OCTOBER 2018, REVISED JANUARY 2019

SANTA MARGARITA RIVER
WATERSHED MANAGEMENT AREA

Water Quality Improvement Plan

Submitted by

COUNTY OF RIVERSIDE, COUNTY OF SAN DIEGO, RIVERSIDE COUNTY FLOOD CONTROL AND WATER CONSERVATION DISTRICT, CITIES OF MENIFEE, MURRIETA, TEMECULA, AND WILDOMAR

** This Page Intentionally Left Blank **

CERTIFICATION STATEMENT

SANTA MARGARITA RIVER WATERSHED MANAGEMENT AREA
WATER QUALITY IMPROVEMENT PLAN

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Table of Contents

Executive Summary **1**
Priority Water Quality Conditions 2
Water Quality Improvement Goals, Strategies, and Schedules 4
Monitoring and Assessment Plan (MAP) 5
Iterative Approach and Adaptive Management 5
1 Introduction **1-1**
1.1 Purpose of the Water Quality Improvement Plan 1-1
1.2 Regulatory Background 1-1
1.2.1 RCFCWCD and the City of Menifee 1-2
1.3 Physical Setting 1-3
1.4 Water Quality Improvement Plan Development and Implementation Process 1-10
1.4.1 Document Overview 1-10
1.4.2 Public Participation Process 1-11
2 Priority Water Quality Conditions **2-1**
2.1 Process to Prioritize Water Quality Conditions 2-1
2.2 Available, Relevant and Appropriately Collected and Analyzed Data Received 2-4
2.2.1 Assessment Areas 2-10
2.2.2 Beneficial Uses and Thresholds to Assess Data 2-13
2.3 Assessment of Receiving Water Conditions 2-15
2.3.1 Step 1. Identify Pollutants and Stressors of Potential Concern in Receiving Waters 2-15
2.3.2 Step 2. Identify PWQCs Potentially Impacting Beneficial Uses (Provisions B.2.a.(3), B.2.a.(6), B.2.a.(7), B.2.a.(8)) 2-27
2.3.3 Identification of Potential PWQCs in Receiving Waters Based on Step 1 and Step 2 Data Assessments 2-41
2.4 Step 3. Assessment of Potential Impacts From Storm Drain Discharges 2-52
2.4.1 Locations of Storm Drain Discharges (Provision B.2.b.(3)) 2-52
2.4.2 Identification of Potential PWQCs Which Storm Drain Discharges May be Contributing (Provisions B.2.b.(1), B.2.b.(2), B.2.b.(4) and B.2.b.(5)) 2-52
2.5 Step 4A Priority Water Quality Conditions 2-59
2.5.1 Priority Water Quality Conditions (Provisions B.2.c.(1)(a-d)) 2-59
2.5.2 Monitoring Data Adequacy and Data Gaps (Provision B.2.c.(1)(e)) 2-62
2.6 Step 5B. Highest Priority Water quality Condition (Provision B.2.c.(2)) 2-64

3 Identification of MS4 Sources of Pollutants and/or Stressors 3-1
3.1 Pollutant Generating Facilities, Areas, and/or Activities 3-4
3.1.1 Pollutant Generating Facilities, Areas, and Activities 3-4
3.1.2 Parks, Recreational and Open Space Areas 3-9
3.1.3 Landfills or Other Treatment Facilities for Municipal Waste 3-9
3.1.4 Areas not Within the Agencies' Jurisdictions 3-10
3.1.5 Location of the Agencies' Stormwater Conveyance Systems 3-10
3.2 Other Potential Sources 3-14
3.2.1 Other Storm Drain Outfalls 3-14
3.2.2 Other NPDES Permitted Discharges 3-14
3.2.3 Other Point Sources 3-15
3.2.4 Non-Point Sources 3-15
3.3 Review of Available Data 3-22
3.3.1 Illicit Discharge Detection and Elimination (IDDE) Programs 3-22
3.3.2 Findings from Major Storm Drain Discharge and Receiving Water Monitoring and Associated Assessments 3-22
3.3.3 Other Data or Studies Related to Pollutant Sources 3-23
3.3.4 Findings from TMDL Alternative Technical Reports 3-24
3.4 Data Adequacy 3-26
3.5 Conclusions From Source Information 3-26
4 Water Quality Improvement Goals, Strategies, and Schedules 4-1
4.1 Goals And Schedules to address eutrophication and nutrient loading 4-2
4.1.1 Geographic Extent of Eutrophication HPWQC 4-2
4.1.2 TMDL Alternative Background 4-4
4.1.3 Numeric Goals and Schedules for the SMR Watershed 4-6
4.2 Strategies and Schedules 4-17
4.2.1 Strategies to Address Eutrophication in the Upper SMR Subwatershed 4-18
4.2.2 Strategies to Address Eutrophication Impacts and Nutrients in the Lower SMR Subwatershed 4-84
4.2.3 Optional WMA Strategies 4-106
4.3 Watershed Management Area Analysis 4-110
5 Monitoring and Assessment Program 5-1
5.1 SMR WMA MAP Description 5-1
5.2 SMR WMA MAP Monitoring Questions 5-1
5.3 General Scope of Monitoring 5-2

5.3.1 Receiving Water Monitoring 5-8
5.3.2 MS4 Outfall Monitoring 5-19
5.3.3 Special Studies 5-26
5.4 Project Organization and Responsibilities 5-30
5.4.1 Monitoring to Assess Progress Toward Achieving Goals and Schedules 5-31
5.5 Reporting and Assessment Program 5-34
5.5.1 Water Quality Improvement Plan Annual Reporting Requirements 5-34
5.5.2 Assessment Program 5-35
6 Iterative Approach and Adaptive Management Process 6-1
6.1 Re-evaluation of Priority Water Quality Conditions 6-3
6.2 Adaptation of Goals, Strategies, and Schedules 6-4
6.2.1 Adaptation of Goals and Schedules 6-5
6.2.2 Adaptation of Strategies and Schedules 6-6
6.3 Adaption of Monitoring and Assessment Program 6-8
6.4 Timing of Adaptive Management Requirements 6-9
6.4.1 Annual Assessments and Adaptive Management 6-9
6.4.2 Permit Term Assessments and Adaptive Management 6-10
6.5 Water Quality Improvement Plan Updates and Reporting 6-13
7 Glossary of Terms 7-1
8 References 8-1

Executive Summary

The Counties of Riverside and San Diego, the Riverside County Flood Control and Water Conservation District (RCFCWCD), and the Cities of Murrieta, Temecula, and Wildomar (collectively known as Copermittees) as well as the City of Menifee have prepared this Water Quality Improvement Plan to comply with requirements in their Municipal Separate Storm Sewer System (MS4) Permit (Order No. R9-2013-0001 as amended by Order No. R9-2015-0001 and Order No. R9-2015-0100; Permit) and to protect the beneficial uses of the receiving waters in the Santa Margarita River (SMR) watershed. The SMR watershed is unique as the least disturbed watershed along the Southern California coast, and the SMR is the longest free flowing, undammed river in the region. The SMR watershed supports a wide variety of beneficial uses related to water supply, agriculture, industry, and aquatic life. Habitat conservation and connectivity within the watershed are important issues to the Copermittees. The major surface water bodies in the SMR watershed are:

- Murrieta Creek;
- Temecula Creek;
- Santa Margarita River; and
- Santa Margarita River Estuary (SMR Estuary).

The Water Quality Improvement Plan was developed in three phases as outlined below, and will be implemented following the process outlined in **Figure ES-1**.

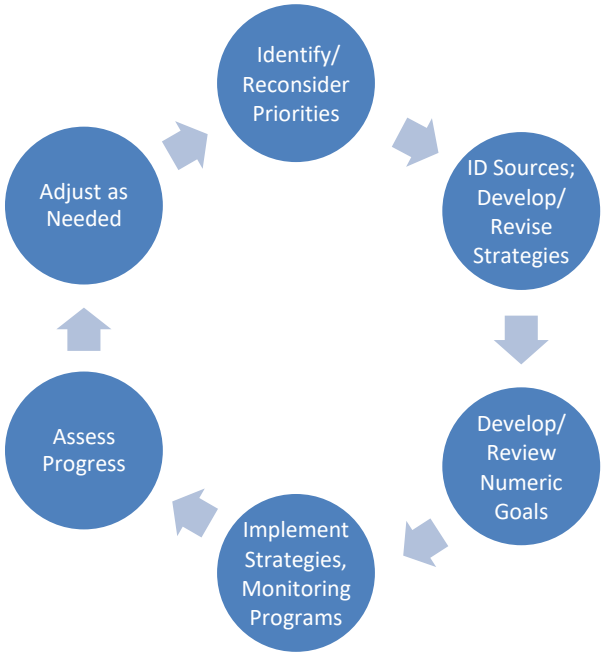

Figure ES-1. Water Quality Improvement Plan Implementation Process

1. The first phase identified the priority and highest priority water quality conditions for the watershed, along with potential water quality improvement strategies (Permit Provision B.2).
2. The second phase identified numeric goals for the highest priority water quality conditions in the watershed, strategies that the Copermittees and the City of Menifee will implement to achieve the numeric goals, and schedules for implementing strategies and attaining goals (Permit Provision B.3).
3. The third phase included development of a monitoring and assessment program to provide feedback to program managers.

During implementation, adaptive management will be utilized to assess progress towards goals and adjust the implementation process as needed.

Chapter 1 provides a brief overview of the SMR watershed and describes the extensive stakeholder process that contributed to the development of the Water Quality Improvement Plan. A Consultation Committee consisting of representatives from the San Diego Regional Water Quality Control Board (Regional Water Board), the environmental community, the development community, and at-large members provided important feedback during development. The public participation process involved the following activities:

- A widely distributed data request to solicit data from the public;
- The public were invited to Consultation Committee meetings, where they received updates on project progress and had the opportunity to provide comments;
- Updates on Water Quality Improvement Plan progress were provided through other watershed meetings that are open to the public; and
- Comments received from the public and the Consultation Committee were considered during the development of the Water Quality Improvement Plan.

PRIORITY WATER QUALITY CONDITIONS

Chapter 2 describes the process to determine priority water quality conditions (PWQCs) for the SMR watershed. To facilitate data analysis for the water quality prioritization process, the watershed was divided into three subwatersheds. The Upper, Middle, and Lower SMR Subwatersheds were delineated based on their hydrologic boundaries (Figure 1-1). The process to determine the PWQCs considered all available data and information on receiving water conditions, Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) listings), Total Maximum Daily Loads (TMDLs) (established or in development), known impacts to beneficial uses, MS4 contributions to water quality conditions, local knowledge about watercourse function, environmental values, community goals, habitat preservation, and input from members of the public and Consultation Committee. Data collected were used to conduct extensive analyses regarding the comparison between historic and current water quality conditions, constituent exceedances, beneficial use impacts, as well as contributions from MS4s to receiving waters. Wet and dry weather conditions were considered independently, as water quality priorities can vary with season. All of these analyses contributed to developing the list of PWQCs. Results show that on the whole, water quality during both dry and wet weather conditions observed in the watershed are trending towards improvement.

The highest priority water quality condition (HPWQC) was selected from the list of PWQCs. The HPWQC provides the basis for selecting watershed strategies and developing goals and schedules during the subsequent phases of Water Quality Improvement Plan development. The HPWQC was determined by evaluating each PWQC against ten criteria related to the extent and impact of the condition. Each PWQC was also evaluated for potential improvements in conditions of receiving water and MS4 discharge quality that can be achieved. Based on the assessment, eutrophication was identified as the highest priority to address. (See **Table ES-1**)

Eutrophication was identified as the HPWQC largely due to 303(d) listings for nutrients, an existing TMDL in Rainbow Creek, the TMDL Alternative (under development) for nutrients and biostimulatory substances in the SMR Estuary and the watershed, the potential impact on beneficial uses from those conditions, the nutrient objective exceedances observed throughout the watershed, and the extent of potential improvements that could be achieved in the condition of the Watershed Management Area (WMA) and discharge quality from MS4s. The eutrophication HPWQC includes two components: 1) eutrophication impacts (elevated algal biomass) and 2) nutrient loading to waterbodies with an adopted TMDL or listed as impaired, including dry weather nutrient loading from both Middle, and Lower SMR Subwatersheds to address the TMDL Alternative for the SMR Estuary, and dry and wet weather nutrient loading to Rainbow Creek to address the Rainbow Creek Nutrient TMDL.

Table ES-1. Highest Priority Water Quality Condition (Eutrophication)

Beneficial Use Category	Highest Priority Water Quality Condition	Temporal Extent	Geographic Extent
Aquatic Life: Eutrophication	Eutrophication impacts (elevated algal biomass)	Dry	SMR Estuary [1], Warm Springs, Redhawk Channel [2]
	Nutrient loading to waterbodies with an adopted TMDL or listed as impaired	Dry	All Middle and Lower SMR Subwatershed subareas, except Fallbrook Creek and Sandia Creek[1]
		Wet	Rainbow Creek

1. MS4 discharges within the following subareas may reach the SMR Estuary during dry weather and contribute to the Eutrophication HPWQC in the Santa Margarita River Estuary: Upper Murrieta Creek and Tributaries, Warm Springs, Santa Gertrudis, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Lower Santa Margarita River, Rainbow Creek and De Luz Creek.
2. Other areas may be added as result of TMDL Alternative development during adaptive management process.

Chapter 3 of this document includes an assessment of potential sources within the watershed contributing to eutrophication and nutrient loading. The source assessment is based on a review of available data and information for potential sources that are likely to be present in the watershed. The main contributor to eutrophication was identified to be algal biomass. Excess algal biomass can be caused by nutrient loading of nitrogen and phosphorus. Such loading is primarily linked to land uses such as orchards, vineyards and nurseries, open scrublands and grasslands, and residential land uses. Additionally, irrigated agriculture was identified as a contributor of total nitrogen loading and roads as a contributor for total phosphorus loading. The mechanisms identified for these non-point source loads to reach a receiving water include stormwater runoff, irrigation return flow (excess irrigation water that reaches a receiving water), and subsurface flow associated with shallow groundwater pathways.

WATER QUALITY IMPROVEMENT GOALS, STRATEGIES, AND SCHEDULES

Chapter 4 defines the goals developed to measure progress, the strategies to be implemented to achieve the goals, and the schedules for implementation of strategies and goal achievement. Through the implementation of strategies and an iterative, adaptive management approach, it is anticipated that the numeric goals will be achieved and the water quality will be improved. The strategies were developed with multiple benefits in mind. They were designed to address the HPWQC, as well as other PWQCs identified in **Chapter 2**.

Within the Middle SMR Subwatershed, the Copermittees and the City of Menifee have the option of demonstrating compliance through one of six pathways. Each pathway includes interim goals, with at least one goal per Permit term, to demonstrate progress toward achieving the final goals. The final goals and timeframe for achieving the goals are based on the *proposed* allocations and schedule in the TMDL Alternative for the SMR Estuary. The Water Quality Improvement Plan goals and schedules may be revised through the adaptive management process, if necessary, to be consistent with the requirements for implementation of the TMDL Alternative for the SMR Estuary.

Within the Lower SMR Subwatershed, numeric goals and schedules were also developed for the Nutrient TMDL in Rainbow Creek. Compliance with the Rainbow Creek Nutrient TMDL final numeric goals can be met in one of five ways, similar to the approach for the eutrophication impacts HPWQC.

Given the different potential sources and jurisdictions in the Upper, Middle, and Lower SMR Subwatersheds, sets of strategies were developed for each jurisdiction in each subwatershed.

For the Middle SMR Subwatershed, the Copermittees and the City of Menifee developed jurisdictional, optional jurisdictional, and optional watershed scale strategies to address the HPWQC. The Copermittees and the City of Menifee also developed an adaptive management approach to implement and evaluate strategies. Each Copermittee will develop and implement a Jurisdictional Runoff Management Program (JRMP) that contains strategies to address the requirements in Provisions E.2 through E.7 of the Permit. As required by the Santa Ana Phase I MS4 Permit, Menifee's jurisdictional program is laid out in its LIP rather than a JRMP. Jurisdictional programs, strategies, and all minimum best management practices (BMPs) established per each Co-Permittee's JRMP will be implemented across all areas within the respective jurisdiction upon the Regional Water Board's acceptance of the Water Quality Improvement Plan.

Strategy implementation will also include enhanced jurisdictional strategies that are specific, locally appropriate, and focused in target areas. Program implementation will be evaluated on an annual basis, and overall progress toward achieving the final Water Quality Improvement Plan goals will be assessed at five year intervals in the Report of Waste Discharge as required for National Pollutant Discharge Elimination System (NDPES) permit renewals. If triggered, and depending on the procurement of funding and necessary approvals, enhanced jurisdictional strategies will be implemented.

In the Lower SMR Subwatershed, San Diego County has developed jurisdictional strategies to address known and suspected sources identified within their inventories, including persistently flowing outfalls and specific land use types (e.g., orchards, vineyards and nurseries, and residential land uses). Jurisdictional strategies target reductions in dry weather flow and address the types of

land use sources that are within the MS4 drainage area. Specific structural strategies such as nutrient-sensitive biofiltration, wetland channels, stream restoration, and channel improvements have also been identified.

Schedules for strategy implementation reflect the time necessary to fully fund, develop, initiate, and complete the chosen strategies. Strategies with relatively high benefit outcomes and low resource requirements are scheduled for earlier implementation. Strategies planned for later years may have implementation requirements that depend on the outcomes of earlier strategies, or might have significant funding needs. Strategies, including schedules for implementation, are included in **Table 4-6** through **Table 4-11** and in **Table 4-14**.

MONITORING AND ASSESSMENT PLAN (MAP)

Chapter 5 outlines the Monitoring and Assessment Plan (MAP) for the SMR watershed to support assessment of progress toward numeric goals and schedules, progress addressing eutrophication and nutrient loading, and each agency's overall efforts to implement the Water Quality Improvement Plan. The SMR watershed MAP is designed with the overall goal of answering the following monitoring questions, which correspond to the numeric goals presented in **Chapter 4**:

- How much has total nitrogen and total phosphorus loading been reduced in the SMR watershed?
- How much has non-storm water flow been reduced at Copermittee outfalls?
- How much has total nitrogen and total phosphorus loading been reduced at Copermittee outfalls?
- Are there sources of pollutants outside of Copermittee control that are causing exceedances of targets?

These questions will be answered through a multi-pronged monitoring approach that includes water quality monitoring in creeks and rivers, the SMR Estuary, and at major outfalls discharging to these waterbodies.

ITERATIVE APPROACH AND ADAPTIVE MANAGEMENT

Chapter 6 outlines the adaptive management process that will be used to evaluate and adapt the Water Quality Improvement Plan. The adaptive management process will be implemented using data collected as part of the MAP, to evaluate whether modifications to goals, schedules, and/or strategies are necessary. Triggers that may prompt program modification include persistent exceedances of water quality standards in receiving waters, new information (e.g., TMDL Alternative implementation requirements, new regulations, etc.), Regional Water Board recommendations, and input received during the public participation process.

1 Introduction

1.1 PURPOSE OF THE WATER QUALITY IMPROVEMENT PLAN

The purpose of this Water Quality Improvement Plan (WQIP) is to guide the development and implementation of jurisdictional runoff management programs of the Counties of Riverside and San Diego, the Riverside County Flood Control and Water Conservation District (RCFCWCD), and the Cities of Murrieta, Temecula, and Wildomar (hereafter referred to as the Copermittees), as well as the City of Menifee, towards achieving the outcome of improved water quality in MS4 (Municipal Separate Storm Sewer System) discharges and receiving waters within the Santa Margarita River (SMR) watershed management area (WMA).

1.2 REGULATORY BACKGROUND

On May 8, 2013, the California Regional Water Quality Control Board (RWQCB) - San Diego Region (Regional Water Board) adopted Order No. R9-2013-0001; National Pollutant Discharge Elimination System (NPDES) Permit No. CAS0109266, NPDES Permit and Waste Discharge Requirements (WDRs) for Discharges from the Municipal Separate Storm Sewer Systems (MS4s) Draining the Watersheds within the San Diego Region (Permit). The Permit was amended by Order No. R9-2015-0001 and Order No. R9-2015-0100 in 2015 to include all participating agencies (Copermittees) in the San Diego Region. The most recent amendment (Order No. R9-2015-0100), which enrolled the Riverside County Copermittees, became effective on January 7, 2016. The Permit covers portions of the counties of San Diego, Orange, and Riverside that reside within the Regional Water Board's jurisdiction.

The Permit has two primary goals[1]:

1) Bring a consistent set of permit requirements to all of the Copermittees within the San Diego Region; and

2) Provide permit requirements that will allow the Copermittees to focus their efforts and resources on achieving goals and desired outcomes toward the improvement of water quality rather than completing specific actions.

As such, the Permit incorporates a strategic planning component that includes short-term and long-term goal setting as well as a requirement to develop a comprehensive program to further the Clean Water Act's objective to protect, preserve, enhance, and restore the water quality and designated beneficial uses of the waters of the state.

The Permit requires two types of planning efforts and plans:

1) Water Quality Improvement Plans (WQIPs) - developed on a watershed basis, these plans identify the highest priority water quality condition(s) (HPWQC(s)) in a watershed as well as the goals, strategies, and schedules to improve discharge and receiving water quality.

2) Jurisdictional Runoff Management Plans (JRMPs)[2] – developed on a jurisdictional basis, describe how the individual Copermittees implement the Permit requirements,

[1] Permit, Attachment F, page F-16.

[2] Strategies for the City of Menifee are described in its equivalent plan referred to as Local Implementation Plan (LIP).

prohibit non-stormwater discharges to the MS4, and reduce pollutants in stormwater discharges from MS4s to the Maximum Extent Practicable (MEP). The JRMPs must also identify how the WQIP strategies will be implemented within each jurisdiction.

Permit Provisions B.1 through B.6 identify the technical requirements that must be addressed during the development and implementation of the WQIP.

- Provision B.1 – Watershed Management Areas - describes the WMAs and responsible agencies covered under the Permit.
- Provision B.2 – Priority Water Quality Conditions - provides the requirements for assessing and determining the priority water quality conditions for the watershed.
- Provision B.3 – Water Quality Improvement Goals, Strategies, and Schedules - contains requirements for developing the goals, strategies, and schedules to guide implementation.
- Provision B.4 – Water Quality Improvement Monitoring and Assessment Program - addresses the monitoring and assessment program that is required to support implementation and assess progress.
- Provision B.5 – Iterative Approach and Adaptive Management Process - describes the iterative approach and the adaptive management process that will be implemented over time to make improvements to the WQIP.
- Provision B.6 – WQIP Submittal, Updates, and Implementation - specifies the submittal and update requirements for the WQIP.

These provisions were adhered to during the development of this WQIP.

1.2.1 RCFCWCD and the City of Menifee

Unlike cities and counties, the RCFCWCD does not own or operate any sanitary sewer systems, public streets, roads, or highways. In 1945, the California State Legislature enacted Act 6642 creating the RCFCWCD. The Act empowered the RCFCWCD to manage flood risk and conserve stormwater for groundwater recharge. In coordination with the United States Army Corps of Engineers, the RCFCWCD developed and constructed a comprehensive system that provides for the regulation and control of flood waters through the use of reservoirs and flood channels. The RCFCWCD operates and maintains storm drains and other appurtenant drainage infrastructure within its service area. The RCFCWCD has no planning, zoning, development permitting, or other land use authority within its service area.

The City of Menifee is located primarily within the geographic jurisdiction of the Santa Ana RWQCB, but a small portion of the city, totaling less than 1.3 square miles, is within the SMR WMA, which is in the geographic jurisdiction of the San Diego RWQCB. Per the Regional Water Board Designation Letter dated October 26, 2015, the entire City of Menifee, including the portion within the SMR watershed, is regulated under the Santa Ana Region MS4 Permit (Order No. R8-2010-0033, as it may be amended or reissued) except for certain provisions specified in the Regional Water Board Designation Letter. One of these provisions is that the City of Menifee is required to participate in the development and implementation of the W QI P for the SMR WMA. Furthermore, the Regional Water Board Designation Letter states that, "The San Diego Water Board shall continue to regulate the City of Menifee under the San Diego Phase I MS4 Permit for the limited purpose of implementing any applicable TMDL."

1.3 PHYSICAL SETTING

The SMR WMA is a unique area because it is the least disturbed watershed along the Southern California coast, and the Santa Margarita River is the longest free flowing, undammed river in the region. The lower 27 miles of the SMR and its estuary are not channelized and support a large population of federally- or state-listed endangered species (County of San Diego, 2005). The SMR WMA encompasses a total area of approximately 741 square miles, spans the southern border of Riverside County and the northern border of San Diego County, and is bordered to the south by the San Luis Rey Watershed and to the west by the San Mateo Creek, Las Flores Creek, and Aliso Creek Watersheds. The watershed is comprised of the following waterbodies: Diamond Valley Lake, Lake Skinner, Vail Lake, Murrieta Creek, Temecula Creek, the SMR, and the SMR Estuary. The Middle SMR Subwatershed includes two major basins, drained by Murrieta and Temecula Creeks.

Murrieta Creek flows between two lengthy strands of the Elsinore fault zone on land that has been down dropped, relatively, by the faulting. Murrieta Creek flows southeasterly from the Wildomar area through the cities of Murrieta and Temecula to the confluence with Temecula Creek. Murrieta Creek and its tributaries drain approximately 222 square miles, with over 50 square miles tributary to Skinner Reservoir, in the northwest portion of the watershed. Temecula Creek has a drainage area of 366 square miles, with steep rugged topography in the Palomar and Thomas Mountain areas and rolling hills below. The upper 316 square miles of this basin is controlled by Vail Lake (completed in 1949).

At the Elsinore fault zone, located at the top of Temecula Gorge and near the City of Temecula, Temecula and Murrieta Creeks merge forming the Santa Margarita River. The Temecula Gorge and Santa Ana Mountains just south of the confluence of the Temecula and Murrieta Creeks serve as a natural barrier delineating the Middle and Lower SMR Subwatersheds. (Rancho California Water District, 2014) From this point, the river flows through the Temecula Gorge and then west into San Diego County for approximately thirty miles before ultimately draining to the SMR Estuary and into the Pacific Ocean.

1.4 SMR WMA SUBWATERSHED AREAS

For purposes of this analysis, the SMR WMA has been divided into three subwatersheds (Figure 1-1):

The Upper SMR Subwatershed;

The Middle SMR Subwatershed; and

The Lower SMR Subwatershed.

The Upper SMR Subwatershed includes all the area in the SMR WMA which drains to the three major manmade lakes: Diamond Valley Lake, Lake Skinner, and Vail Lake; and comprises approximately 385 square miles. Approximately 316 square miles of the subwatershed drain to Vail Lake, 51 square miles drain to Lake Skinner, and 18 square miles of undeveloped area drain to Diamond Valley Lake. Land uses for the subwatershed are shown in Figure 3-1. The Upper SMR Subwatershed includes the following entities/areas:

County of Riverside – 55% of the land area (213 square miles)

- Anza[3] – 12% of the County of Riverside land area (25 square miles)
- Aguanga[3] – 6% of the County of Riverside land area (14 square miles)
- Lake Riverside[3] – 3% of the County of Riverside land area (7 square miles)

Tribal, State and Federal lands – 37% of the land area (143 square miles)

County of San Diego – 8% of the land area (29 square miles)

RCFCWCD – <0.01% of the land area (0.013 square miles)

The Middle SMR Subwatershed is located inland along and east of the I-15 corridor and is approximately 201 square miles. The Middle SMR Subwatershed includes the following entities/areas:

County of Riverside – 53% of the land area (106 square miles)

City of Murrieta – 16% of the land area (33 square miles)

City of Temecula – 15% of the land area (30 square miles)

City of Wildomar – 8% of the land area (16 square miles)

Tribal, State and Federal lands – 6% of the land area (12 square miles)

City of Menifee – 1% of the land area (2 square miles – 815 acres)

RCFCWCD – 1% of the land area (2 square miles – 836 acres)

County of San Diego – <0.1% of the land area (0.13 square miles)

The Lower SMR Subwatershed spans the area downstream of the Temecula Gorge entrance to the Pacific Coast and is approximately 156 square miles. The Lower SMR Subwatershed includes the following entities/areas:

Tribal, State and Federal lands – 46% of the land area (71 square miles)

County of San Diego – 28% of the land area (43 square miles)

County of Riverside – 26% of the land area (40 square miles)

City of Temecula – 1% of the land area (1 square mile – 738 acres)

Vail Lake, Lake Skinner, and Diamond Valley Lake are operated to provide potable water supply. The 44,200 acre-feet Lake Skinner was formed by construction of a dam on Tucalota Creek. Vail Lake is a 49,370 acre-feet reservoir located at the confluence of Temecula Creek, Wilson Creek, and Kolb Creek. Diamond Valley Lake is Southern California's largest reservoir with a capacity of approximately 810,000 acre-feet (264 billion gallons). Diamond Valley Lake covers 4,500 surface acres and holds enough water to meet the area's emergency and drought needs for six months. Vail Lake, Lake Skinner, and Diamond Valley Lake provide important resources for municipal water supply for use by local water agencies. Vail Lake is owned by Rancho California

[3] Census Designated Area

Water District (RCWD); Diamond Valley Lake and Lake Skinner are owned by the Metropolitan Water District of Southern California.

Vail Lake and Skinner Lake capture the majority of incoming flows from Temecula Creek, Wilson Creek, Kolb Creek, and Tucalota Creek. These lakes are operated based on water supply and groundwater recharge considerations, and not for flood control purposes. Virtually all runoff received in these reservoirs is conserved for municipal, industrial, and agricultural use. Nonetheless, the storage capacity of each reservoir typically allows most storm events to be captured and stored. At these reservoirs, the majority of flows are contained and are only released into the downstream channels during higher magnitude storm events or when a series of back-to-back storms occurs. For example, storm flows have only been released from Vail Lake during two storm seasons since 1947. Lake Skinner has not released uncontrolled storm flows since 1975. Diamond Valley Lake releases flows to downstream drainage channel only in emergencies. Therefore, the Upper SMR Watershed is hydrologically disconnected from the Middle SMR Watershed in all but the very largest storms or storm series.

In most years, controlled releases from Vail Lake during the wet season (November – April) are infiltrated in the extensive Valle de los Caballos spreading basins. Although RCWD is required to meet in-stream flow requirements at the Temecula Gorge by releasing 4,000 acre-feet of water per year, this requirement is currently met by a separate discharge of untreated imported water directly into Murrieta Creek, and not by any releases from Vail Lake.

Beneficial Uses for the streams in the SMR WMA are shown in Appendix 2. However, the lakes also have important Beneficial Uses including:

- MUN: Municipal and Domestic Supply
- AGR: Agricultural Supply
- IND: Industrial Service Supply
- PROC: Industrial Process Supply
- GWR: Ground Water Recharge (potential Beneficial Use for Lake Skinner)
- REC-1: Contact Water Recreation (limited to fishing from shore or boat)
- REC-2: Non-contact Water Recreation
- WARM: Warm Freshwater Habitat
- WILD: Wildlife Habitat
- POW: Hydropower Generation (Diamond Valley Lake only)

The WQIP recognizes the importance of protecting the lakes from any adverse water quality impacts. The importance of these lakes is called out in the Basin Plan (Chapter 2: Reservoirs and Lakes):

> "The water resources with the greatest diversity of beneficial uses in the Region are the manmade water storage reservoirs and lakes. Located in nearly all of the Region's hydrologic units, these reservoirs and lakes intercept surface runoff and store imported water supplies.
>
> As such, the storage reservoirs serve as: (1) sources of supply for municipalities, agricultural areas, and industrial operations; (2) recreational bodies; and (3) habitats for fish and wildlife. In a few cases, such as reservoirs used primarily for drinking water, REC-1 uses can be restricted or prohibited by the entities that manage these waters. Many

of these reservoirs, however, are designated as potential for REC-1, reflecting federal Clean Water Act goals."

Population

The Upper SMR Subwatershed has very low population density compared to the Middle SMR Subwatershed (Figure 1-2). Recent estimates from the California Department of Finance 2017 show that there are 321,150 people living in the entire SMR WMA, whereas 2010 Census data shows approximately 15,400 people (5% of the total WMA population) live in the Upper SMR Subwatershed, which comprises approximately 52% of the total SMR WMA. Overall, the population density is low relative to the other subwatersheds. The census-designated areas of Anza, Lake Riverside, and Aguanga, and an area east of Lake Skinner contain most of the population. The small area of density shown in the southwestern corner of the WMA in San Diego County in Figure 1-2 is part of a larger census tract, and most of the population is actually in the San Luis Rey watershed. There is very little developed land in this area.

Infrastructure

Drainage facilities, roads, and receiving waters identified in the Basin Plan are shown in Figure 1-3. There is very limited drainage infrastructure present in the subwatershed. There are two facilities owned by the RCFCWCD: 1) Anza Creek Channel is a 3,500-foot long 30-foot wide X 7-foot deep trapezoidal concrete drainage channel adjacent to and on the south side of Highway 371 in the Anza area; 2) Sage Road Bridge over Wilson Creek is an approximately 750-foot long bridge and a 1.25 acre vegetated mitigation area. Figure 1-3 also shows 115 culverts owned by the County of Riverside that are primarily associated with County roads. No major outfalls have been identified within this portion of the WMA within either Riverside or San Diego County.

Roads

The County of Riverside owns and maintains Primary, Secondary, and lesser roads in the subwatershed as shown in Figure 1-3. Most roads lack curb and gutter, and storm runoff from these roads is managed by infiltration along the road shoulders, by conveying flows under roads via culverts, in some cases surface drainage in natural channels flows over and across roads. Storm runoff may also flow along roadside ditches for short distances. The County of San Diego maintains one single road in this portion of the WMA. The road cuts across the south eastern portion of the WMA through a sparsely populated area for about 6 miles. The county maintains approximately 35 culverts along this road.

Tribal, State, and Federal Lands

The Upper SMR Subwatershed contains large areas of land that are outside the jurisdiction of the counties of Riverside and San Diego, including the Cahuilla, Pechanga, and Ramona Reservations, National Forest and Bureau of Land Management Lands, and the San Felipe Valley Wildlife Area managed by the California Department of Fish and Wildlife (Figure 1-2). These areas comprise approximately 37% of the Upper SMR Subwatershed.

1.5 WATER QUALITY IMPROVEMENT PLAN DEVELOPMENT AND IMPLEMENTATION PROCESS

The WQIP has been developed in three phases, according to the process described within the Permit (Provision F.1).

Phase 1: Priority water quality conditions, the high priority water quality conditions, potential sources, and potential water quality improvement strategies were identified (Provision B.2).

Phase 2: Numeric goals for the HPWQC and strategies that the Copermittees and the City of Menifee will implement to achieve the numeric goals were developed (Provision B.3).

Phase 3: A monitoring and assessment program was designed to provide feedback to program managers on progress towards goals (Provision B.4).

An adaptive management process will be utilized during implementation to assess progress towards goals and adjust the implementation process as needed (Provision B.5). The process for implementation of the WQIP is outlined in **Figure 1-2**.

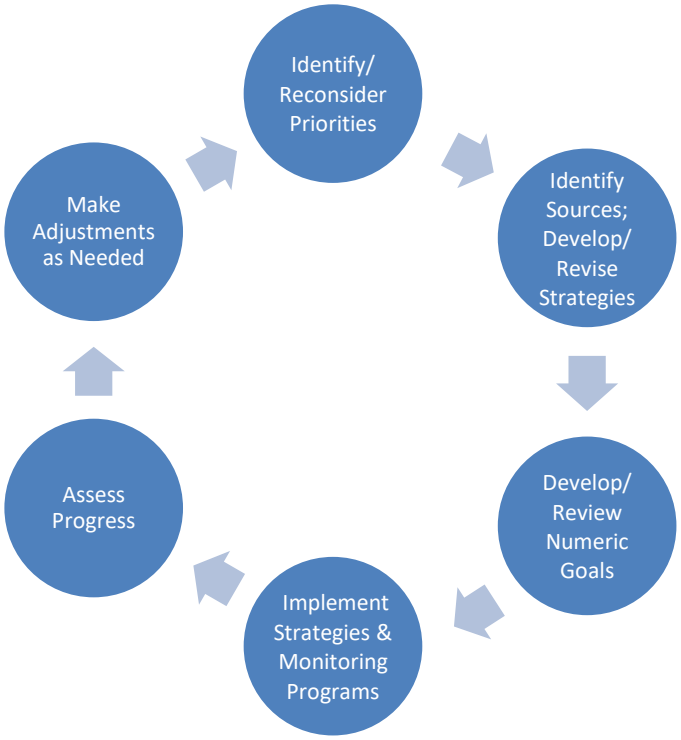

Figure 1-2. Water Quality Improvement Plan Implementation Process

1.5.1 Document Overview

The WQIP is organized into seven chapters. **Chapters 2 - 6** address specific Permit requirements for Plan development (**Table 1-1**). **Chapter 7** contains a glossary of terms and **Chapter 8** contains a list of references cited within the document.

Table 1-1. Structure of the Water Quality Improvement Plan and Associated Permit Requirements

Chapter Content	Permit Requirements Addressed (Provision)
Chapter 1. Introduction	
Chapter 2. Priority Water Quality Conditions	
Water quality priorities identified after evaluating receiving water conditions and impacts from MS4 discharges and potential water quality improvement strategies.	B.2.a-c. Priority Water Quality Conditions
Chapter 3. Identification of MS4 Sources of Pollutants and/or Stressors	
An analysis to identify and prioritize known and suspected sources of stormwater and non-stormwater pollutants associated with MS4 discharges that may cause or contribute to eutrophication or nutrient loading within the watershed.	B.2.d. Identification of MS4 Sources of Pollutants and/or Stressors B.2.e. Identification of Potential Water Quality Improvement Strategies
Chapter 4. Water Quality Improvement Goals and Schedules	
Watershed interim and final goals, along with strategies and schedules developed to achieve the goals.	B.3 Water Quality Improvement Goals, Strategies and Schedules
Chapter 5. Monitoring and Assessment Program	
Integrated Monitoring and Assessment Program developed based on the requirements of the Permit and Plan process.	B.4. Monitoring and Assessment Program
	D. Monitoring and Assessment Program Requirements
Chapter 6. Iterative Approach and Adaptive Management	
Elaboration on the adaptive management processes, including the frequencies of adaptation required by the Permit (annual versus once per Permit term), triggers, and resulting actions.	B.5 Iterative Approach and Adaptive Management
Chapter 7. Glossary of Terms	
Chapter 8. References	

In addition, as part of the WQIP's development, the Copermittees and the City of Menifee created a "crosswalk" to identify which Permit provisions are addressed in specific document sections (**Appendix 1A**). This crosswalk is intended to ease the review process and is based on the Permit checklist used by the Regional Water Board to evaluate the WQIP. The crosswalk includes Permit requirements, comments from the Regional Water Board based on their review of the draft documents, and responses by agencies to comments based on revisions to the WQIP.

1.5.2 Public Participation Process

The Copermittees and the City of Menifee implemented a public participation process as part of Plan development in accordance with Permit Provision F. The process included data solicitation, the formation and participation of a Consultation Committee, presentations at public meetings and other outreach to the community, and participation in the Santa Margarita River Nutrient Initiative Group (SMRNIG), to provide opportunities for public input on the WQIP. Drafts of the priority water quality conditions, numeric goals, water quality improvement strategies, and schedules were submitted to the Regional Water Board as required and were subsequently posted for public

review. Feedback and comments received during Plan development were considered in the process and helped to shape the WQIP.

1.5.2.1 Data Solicitation

On April 22, 2016, the Copermittees issued a public request for data to a distribution list of 83 interested parties, and posted the data solicitation on the RCFCWCD's website, allowing 30 days for submittal of information. The data solicitation closed on May 23, 2016. The notice requested any available quantitative or qualitative data related to water quality within the watershed. Although widely distributed and targeting relevant stakeholders, as well as the general public, no data was received in response to the data solicitation. As a follow-up, Copermittees and the City of Menifee requested and received water quality data from the SMRNIG which was incorporated into the analysis and assisted in prioritization of water quality conditions.

1.5.2.2 Consultation Committee

The Copermittees and the City of Menifee formed a Consultation Committee to receive recommendations during the development of the WQIP (Provision F.1.a.(1)(b)). The Permit includes requirements for the Consultation Committee to review and provide recommendations at key points during the WQIP development process. Feedback from the Committee is vital to the development of the WQIP. The Consultation Committee consisted of representatives from the Regional Water Board, the environmental community, the development community, community organizations, neighborhood groups, and businesses all sharing a commitment to improve water quality. The Consultation Committee included the following individuals:

Required Members

Erica Ryan (San Diego Regional Water Quality Control Board)

Terri Biancardi (Environmental Community)

Dr. Mark Grey, Clint Lorimore (*alternate*) (Development Community)

At Large Members

Ben Drake (Temecula Winegrowers Association)

Andy Domenigoni (Riverside County Farm Bureau)

Kyle Cook (Camp Pendleton Marine Base)

Pablo Bryant (Santa Margarita Ecological Reserve)

Laurie Correa (Western Riverside County Regional Conservation Authority)

Rick Neugebauer (Temecula/Elsinore/Anza/Murrieta Resource Conservation District (TEAM-RCD))

The Copermittees and the City of Menifee hosted three Consultation Committee meetings during development of the WQIP. The meetings were all open to the public, were held at varied times and locations, and publicly noticed to provide ample time and opportunity for the public to participate. Dates and content of the Consultation Committee meetings are summarized in **Table 1-2**. A summary of comments received and their consideration within Plan development are included in the Public Review Process discussion in **Section 1.5.2.5**.

Table 1-2. Summary of Consultation Committee Meetings

Consultation Committee Meeting Date/Location	Key Content of the Meeting
September 7, 2016 Rancho California Water District	• Overview of the Planning Process • Preliminary Prioritization Methodology • Results and Initial Priority Water Quality Conditions • Potential Water Quality Improvement Strategies
May 17, 2017 City of Wildomar	• Revisions to the Prioritization Process • Priority Water Quality Conditions • Proposed goal and schedules • Overview of strategies and schedules • Watershed Management Area Analysis
October 17, 2017 City of Temecula	• Watershed Management Area Analysis Updates • Monitoring and Assessment Program • Adaptive Management

1.5.2.3 Additional Public Participation

In August 2017, the issue of poor attendance at public meetings convened to support Water Quality Improvement Plan development in the San Juan WMA was discussed with RWCQB staff. Arising from this discussion was agreement to implement an alternate approach based on presentations at scheduled council meetings. This approach was accepted, contingent upon informational materials being clearly made available to all individuals attending the meeting and the presentations, including a request for further public engagement. Based on this acceptance, presentations on the SMR WQIP were made at the following council meetings:

October 24, 2017 – City Council Presentation, City of Temecula

November 1, 2017 – City Council Presentation, City of Menifee

November 7, 2017 – City Council Presentation, City of Murrieta

November 8, 2017 – City Council Presentation, City of Wildomar

The same presentation was also provided to the following County Supervisors:

October 18, 2017 – Supervisor Washington briefing, Riverside County Administration Center

October 30, 2017 – Supervisor Jeffries briefing, Riverside County Administration Center

In addition to the presentations, the Copermittees participated in the following public meetings and events to solicit input on the WQIP:

June 1, 2016 – Upper Santa Margarita River Watershed Integrated Regional Water Management Region Stakeholder Meeting

July 12, 2016 – Riverside County Board of Supervisors Meeting

August 9, 2016 – City Manager's Roundtable Meeting

September 7, 2016 – Upper Santa Margarita River Watershed Integrated Regional Water Management Region Stakeholder Meeting

January 19, 2017 – Western Riverside Council of Governments (WRCOG) Technical Advisory Committee

January 30, 2017 – Meeting with City Managers and Public Works Directors

April 22, 2017 – RCFCWCD booth at the Earth Day Celebration

June 7, 2017 – Upper Santa Margarita River Watershed Integrated Regional Water Management Region Stakeholder Meeting.

1.5.2.4 Santa Margarita River Nutrient Initiative Group (SMRNIG)

The Copermittees also regularly participate in the SMRNIG which includes cities and counties, utility districts, Caltrans, scientists, tribes, non-governmental organizations (NGOs), United States Geological Survey (USGS), Camp Pendleton, Farm Bureau, and RWQCB staff that periodically meet to focus on nutrient-related issues in the SMR Estuary. While the SMRNIG did not participate directly in WQIP development, they have conducted extensive modeling efforts in support of a Total Maximum Daily Load (TMDL) Alternative for the SMR Estuary for nutrients, and their work has provided valuable insight and scientific information used in the development of this Plan. With respect to the SMR Copermittees, this WQIP will be a key implementation mechanism for the TMDL Alternative. The TMDL Alternative is expected to be activated through the issuance of an Investigative Order by the Regional Water Board. For simplicity, hereinafter this WQIP will use the term "TMDL Alternative" to refer to this action, pending finalization of the implementation approach to be conducted by the Regional Water Board. Further discussion of the TMDL Alternative process and how it dovetails with the WQIP is provided in **Chapters 2, 3,** and **4**.

1.5.2.5 Public Review Process

In addition to public outreach conducted and input received during development of the WQIP, **Chapters 2** and **3** underwent formal public review processes upon submittal to the Regional Water Board.

1.5.2.5.1 Chapter 2 – Priority Water Quality Conditions and Potential Strategies

Following the first Consultation Committee meeting, draft work products of **Chapter 2** were distributed to the Consultation Committee for review and feedback in September 2016. Draft work products distributed included:

- Summary table of the Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) listings) in the watershed,
- Summary table of the datasets used in the evaluation of water quality conditions,
- Maps of the monitoring locations within the watershed,
- Flowchart describing the draft prioritization process,
- Summary tables showing the results of the ranking process (including all evaluations and scoring), and

- Table of potential strategies to address the priority and highest priority water quality conditions identified for the watershed.

In September 2016, the Copermittees and the City of Menifee received two sets of comments from members of the Consultation Committee. To keep the Consultation Committee informed of progress and direction, Copermittees and the City of Menifee provided drafts of the Executive Summary and section related to Highest Priority Water Quality Conditions with updated results for review and additional comments on November 23, 2016. Several sets of comments were received from Consultation Committee members, including one set of written comments from the Regional Water Board received on December 8, 2016.

The initial complete draft of **Chapter 2** (Priority Water Quality Conditions) considered and addressed all comments received, as appropriate, and was submitted to the Regional Water Board on January 5, 2017 and subsequently released for public comment. The public comment period ended on February 20, 2017. Comment letters were received from one member of the public on January 22, 2017 and from the Regional Water Board on March 30, 2017. All comments received were considered in revisions to **Chapter 2**. The primary focus of the comments was related to the process to identify priority water quality conditions (PWQCs) and the HPWQC(s) for the watershed and source information (i.e., municipal parks and landfills).

All comments received during development of **Chapter 2** are included in the crosswalk provided in **Appendix 1A** and **Appendix 1B** and have been considered and addressed as appropriate.

In response to comments received from the Consultation Committee and from the public, the following changes were made to the analyses and findings presented in **Chapter 2**:

- Watershed delineations were revised based on hydrology only, not on political boundaries;
- PWQCs and the HPWQC were identified by hydrologic subareas and subwatersheds and Copermittees and the City of Menifee were assigned responsibility based on their land areas within the hydrologic subareas;
- The prioritization process was revised to consider current TMDLs, TMDLs under development, and 303(d) listings more explicitly and earlier in the process;
- Included assessment of California Rapid Assessment Method (CRAM) index scores and evidence of erosion in the analysis;
- Available loading information was considered specific to various sources;
- The prioritization process was revised and includes a detailed description of how sensitive or highly valued received waters were considered and the results;
- Perennial/non-perennial criteria were removed from the revised prioritization process and the assessments no longer exclude areas based on flow;
- The HPWQC selection process was revised to address all requirements under Permit Provision B.2;
- Source information was updated to ensure that consistent, accurate information was included for all Copermittees and the City of Menifee;

- Language was added to source discussion to clarify the extent to which Copermittees and the City of Menifee have jurisdiction over agriculture;
- IC/ID information was updated to include five years of IC/ID data and related sources;
- Potential strategies tables were updated to better reflect the relationships between the strategies and the benefits to the PWQCs and HPWQC;
- Text and figures were modified for clarity and simplicity to better reflect the information considered within the prioritization process;
- The public participation process was updated to include additional outreach through public meetings;
- Clarification was added to describe how the City of Menifee and RCFCWCD were included in the assessment and prioritization process.

Based on comments received on the draft of **Chapter 2**, subsequent discussions with Regional Water Board and stakeholders, and a second Consultation Committee meeting held on May 17, 2017, the Copermittees and the City of Menifee submitted a revised draft of **Chapter 2** and an initial draft of **Chapter 3** to the Regional Water Board on July 7, 2017. The combined document was subsequently posted for public review by the Regional Water Board, with comments due by August 10, 2017. There were no further comments received from the public. Four sets of comments were received from Consultation Committee members, however, only comments from the Regional Water Board, received on October 11, 2017, are relevant to **Chapter 2**. Based on these comments, further revisions were made to **Chapter 2**. A summary of the key changes is provided below:

- Additional studies were considered in the evaluation of priorities and sources;
- Facilities, areas, and activities for which RCFCWCD is responsible were described in greater detail and a figure was added;
- Clarification was provided related to the geographic extent of the PWQCs and HPWQC with respect to the connectivity of MS4 discharges to receiving waters;
- Technical work related to the TMDL Alternative for eutrophication in the SMR Estuary was more fully incorporated into the evaluation of priorities and sources;
- Potential nutrient contributions from agriculture were better characterized for the watershed as a whole and for discharges that could be conveyed through the Copermittees' MS4s;
- Clarification was added related to regulation of discharges from agriculture, noting that discharges from agriculture that enter the Copermittee's MS4 is under their control;
- Source information, previously included in an appendix, was moved into **Chapter 2** and additional source information was added (subsequently updated to **Chapter 3**); and

- Potential strategies were updated to better relate to the PWQCs and HPWQC and to provide more detail.

1.5.2.5.2 Chapter 3 – Goals, Strategies, and Schedules[4]

In addition to the second Consultation Committee meeting, each Copermittee and the City of Menifee met with Regional Water Board staff during May 2017 to discuss their jurisdictional strategies. Following these meetings, an initial draft of **Chapter 3** (Goals, Strategies, and Schedules) was distributed to the Consultation Committee for review and feedback in June 2017. Comments received from the Consultation Committee by June 15, 2017 on **Chapter 3** are included in **Appendix 1B**. A combined document including a revised **Chapter 2** and the initial public draft of **Chapter 3** incorporated these comments and was submitted to the Regional Water Board on July 7, 2017. The draft was subsequently posted for public review, with comments due by August 10, 2017. There were no further comments received from the public. Four sets of comments were received from Consultation Committee members, including one set of written comments from the Regional Water Board received on October 11, 2017. Based on these comments, revisions have been made to **Chapter 3**. A summary of the key changes to **Chapter 3** in response to comments is provided below:

- Definitions were added for specific terms where needed (e.g., controllable);
- Rainbow Creek Nutrient TMDL compliance analysis and approach was revised;
- The "menu" approach for strategies was abandoned and tables of selected strategies were included in the document;
- Strategies were updated to ensure that each Copermittee addressed Permit Provisions E.2 – E.7;
- Strategies have been modified to include coordination with water districts;
- Strategies updated to include more specificity with respect to which PWQCs/HPWQC, sources, and conditions (i.e., dry/wet/both weather conditions) are addressed;
- Strategies were updated to include frequency as applicable; and
- Optional strategies were updated to include a better description of resources and triggers.

[4] In consideration of further comments, Chapter 3 – Goals, Strategies, and Schedules, was subsequently re-numbered to Chapter 4 with the addition of a chapter discussing sources.

2 Priority Water Quality Conditions

The first phase of the WQIP development identified the PWQCs associated with MS4 discharges that will be addressed by the WQIP. PWQCs are "pollutants, stressors and/or receiving water conditions that are highest threat to receiving water quality or that most adversely affect the quality of receiving waters."[5] To identify the PWQCs, the Copermittees and the City of Menifee used a prioritization process that identified the pollutants, stressors, and conditions that could impact each of the beneficial uses present in the watershed, assessed whether those pollutants, stressors, and conditions were present at levels that could be of concern for the beneficial uses, and assessed the potential contribution from MS4s to the identified conditions. The prioritization process utilized available physical, chemical, and biological data, considered known impacts to beneficial uses, and incorporated local knowledge and information about watercourse function, environmental values, community goals, and habitat preservation to determine the PWQCs and HPWQC. **Chapter 2** provides an overview of this prioritization process, the assessment results for each step in the process, and the resulting PWQCs and HPWQC identified as a result of the analysis.

2.1 PROCESS TO PRIORITIZE WATER QUALITY CONDITIONS

The developed prioritization process follows the order outlined in Permit Provisions B.2.a (Assessment of Receiving Water Conditions), B.2.b (Assessment of Impacts from MS4 Discharges), and B.2.c (Identification of Priority Water Quality Conditions). Available data were compiled and prepared for analysis by grouping the data into assessment areas, identifying the beneficial uses in the assessment areas, determining the physical, chemical and biological indicators that could impact the beneficial uses, and determining the analysis process and thresholds to use to assess potential impacts on beneficial uses. After the data were compiled and prepared for analysis, a four step process was used to identify the PWQCs. An overview of the prioritization approach is illustrated in **Figure 2-1** and detailed in **Figure 2-2**. **Table 2-1** provides an overview of how the prioritization process relates to the Permit requirements and the section that provides the assessment process and results for each prioritization step.

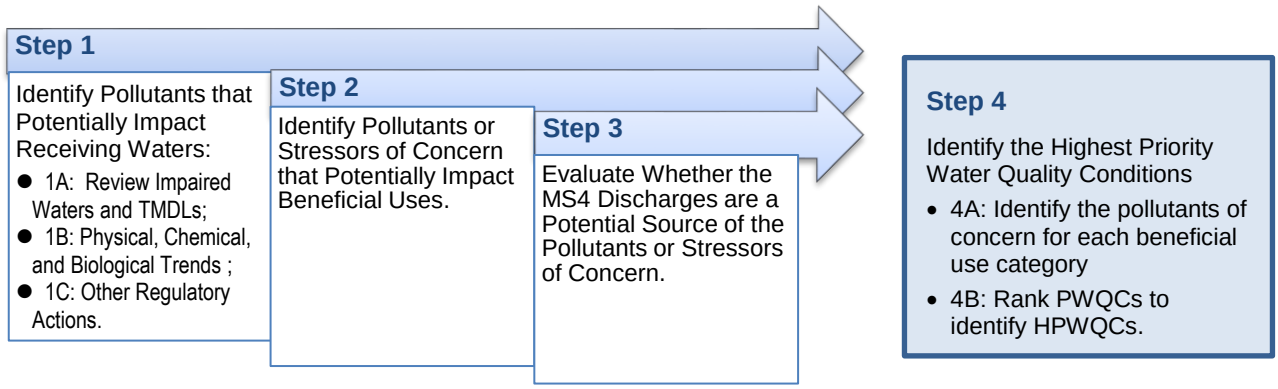

Figure 2-1. Prioritization Process

[5] Provision B.2.c.(1).

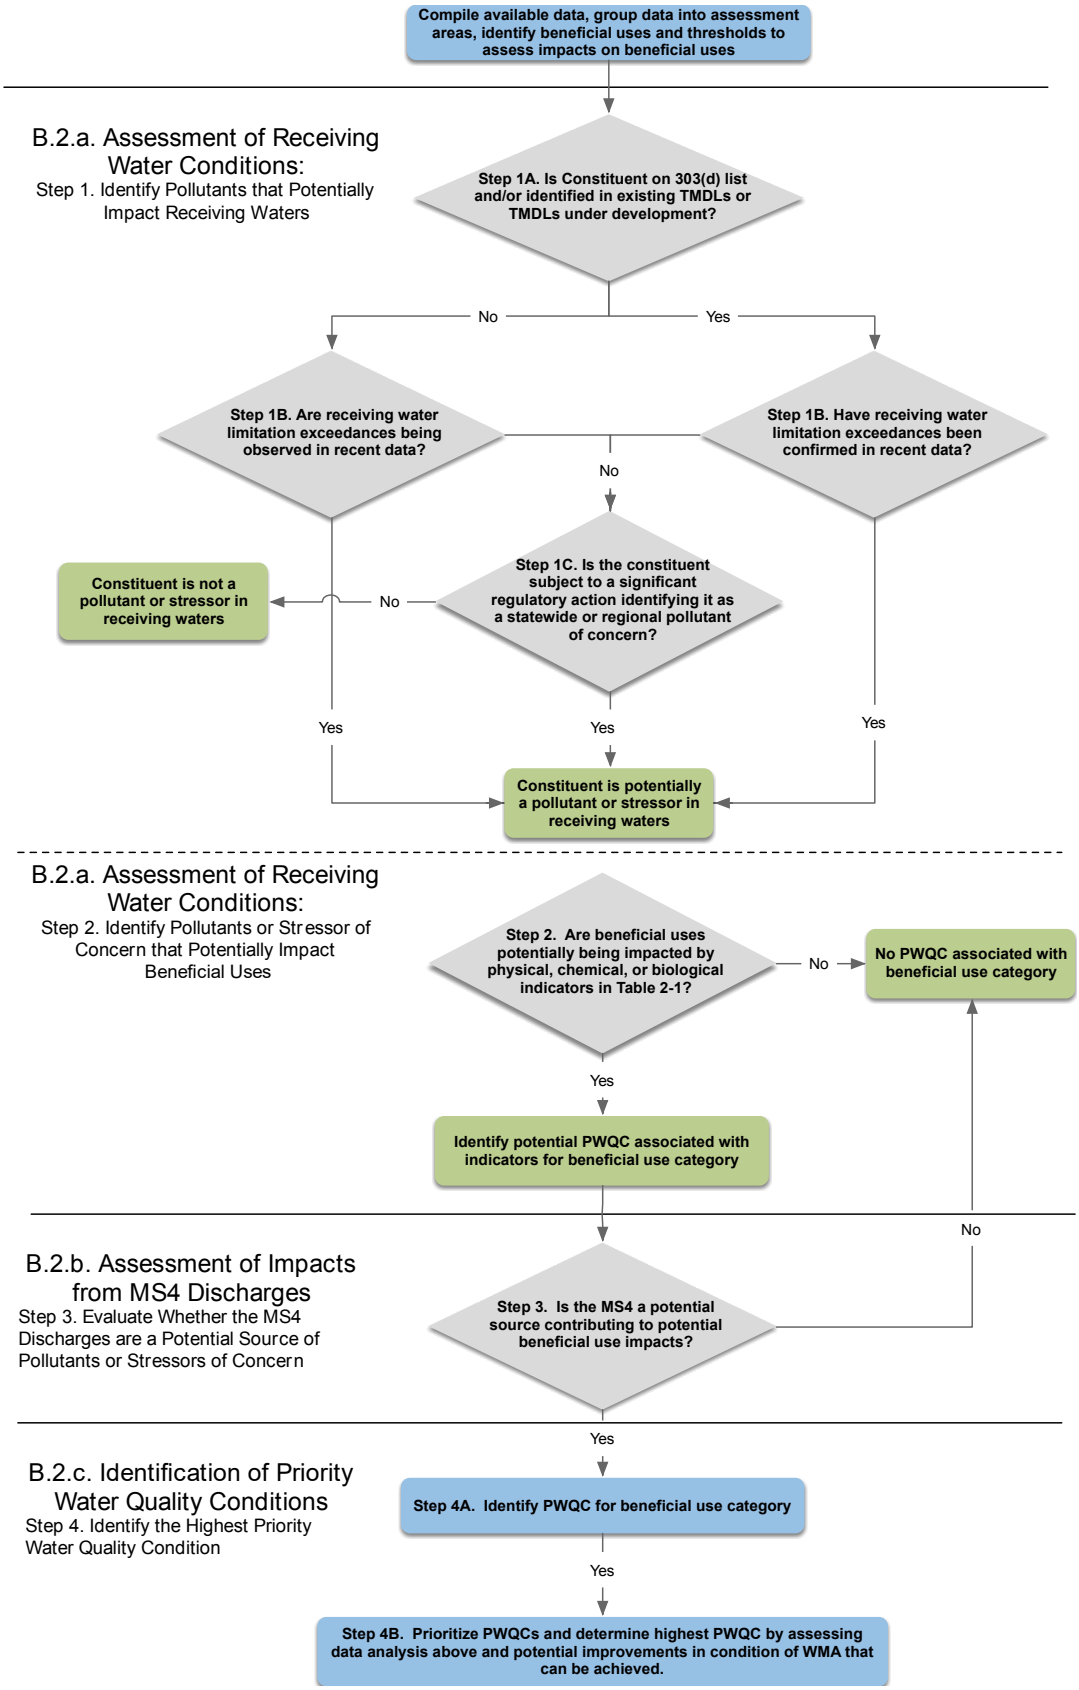

Figure 2-2. Prioritization Process for the SMR WMA

Table 2-1. Prioritization Process Overview and Associated Permit Requirements

Prioritization Step	Permit Requirements Addressed (Provision)
2.3 - B.2.a. ASSESSMENT OF RECEIVING WATER CONDITIONS	
2.3.1 - Step 1. Identify Pollutants and Stressors of Potential Concern in Receiving Waters	
2.3.1.1 – Step 1A. Impaired Receiving Waters and Total Maximum Daily Loads	B.2.a(1) Receiving waters listed as impaired on the Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List)
2.3.1.2 – Step 1A. Impaired Receiving Waters and Total Maximum Daily Loads	B.2.a(2) TMDLs adopted and under development by the Regional Water Board
2.3.1.3 – Step 1B. Evaluation of Receiving Water Limitation Exceedances and Comparison to Historical Conditions	B.2.a(4) Receiving water limitations of Permit Provision A.2 B.2.a(5) Known historical versus current physical, chemical, and biological water quality conditions B.2.a(6) Available, relevant, and appropriately collected and analyzed chemical receiving water monitoring data
2.3.1.4 – Step 1C. Identify Significant Regulatory Actions	N/A
2.3.2 - Step 2. Identify PWQCs Potentially Impacting Beneficial Uses	B.2.a(3) Sensitive or highly valued receiving waters[6] B.2.a(6) Available, relevant, and appropriately collected and analyzed physical, chemical, and biological receiving water monitoring data B.2.a(7) Available evidence of erosional impacts in receiving waters due to accelerated flows (i.e., hydromodification) B.2.a(8) Available evidence of adverse impacts to the chemical, physical, and biological integrity of receiving waters;
2.4 - B.2.b. ASSESSMENT OF IMPACTS FROM MS4 DISCHARGES	
2.4 – Step 3. Assessment of Potential MS4 Discharge Impacts	B.2.b(1) The discharge prohibitions of Provision A.1 and effluent limitations of Provision A.3 B.2.b(2) Available monitoring data from the Copermittees' MS4 outfalls B.2.b(3) Locations of each Copermittees' MS4 outfalls that discharge to receiving waters B.2.b(4) Locations of MS4 outfalls that are known to persistently discharge non-stormwater to receiving waters likely causing or contributing to impacts on receiving water beneficial uses B.2.b(5) Locations of MS4 outfalls that are known to discharge pollutants in stormwater causing or contributing to impacts on receiving water beneficial uses

[6] Defined in Order No. R9-2013-0001 as estuaries designated under the National Estuary Program under Clean Water Act Section 320, marine protected areas, wetlands defined by the State or U.S. Fish and Wildlife Service's National Wetlands Inventory as wetlands, waters having the Preservation of Biological Habitats of Special Significance (BIOL) beneficial use designation, and receiving waters identified as Areas of Biological Significance, or areas recognized as sensitive or highly valued by the Copermittees.

Prioritization Step	Permit Requirements Addressed (Provision)
2.5 and 2.6 - B.2.c. IDENTIFICATION OF PRIORITY WATER QUALITY CONDITIONS	
2.5. – Step 4A. Priority Water Quality Conditions	B.2.c(1) The Copermittees must use the information gathered for Provisions B.2.a and B.2.b to develop a list of priority water quality conditions as pollutants, stressors and/or receiving water conditions that are the highest threat to receiving water quality or that most adversely affect the quality of receiving waters. The list must include the following information for each priority water quality condition: • The beneficial use(s) associated with the priority water quality condition; • The geographic extent of the priority water quality condition within the Watershed Management Area, if known; • The temporal extent of the priority water quality condition (e.g., dry weather and/or wet weather); • The Copermittees with MS4 discharges that may cause or contribute to the priority water quality condition; and • An assessment of the adequacy of and data gaps in the monitoring data to characterize the conditions causing or contributing to the priority water quality condition, including a consideration of spatial and temporal variation.
2.6 – Step 4B. Highest Priority Water Quality Conditions	B.2.c(2) The Copermittees must identify the highest priority water quality conditions to be addressed by the Water Quality Improvement Plan, and provide a rationale for selecting a subset of the water quality conditions identified pursuant to Provision B.2.c.(1) as the highest priorities. B.2.a(9) The potential improvements in the overall condition of the watershed management area that can be achieved. B.2.b(6) The potential improvements in the quality of discharges from the MS4s that can be achieved.

2.2 AVAILABLE, RELEVANT AND APPROPRIATELY COLLECTED AND ANALYZED DATA RECEIVED

The Copermittees and the City of Menifee identified the available data and information for receiving water conditions, MS4 discharges, and sources of pollutants within the SMR WMA. Data were obtained from Copermittees, publicly available datasets, and through a public request for data (as described in **Section 1.5.2.1)**.

Sources of raw data available for the assessment are listed in **Table 2-2**. The datasets obtained were from the following sources:

- RCFCWCD MS4 NPDES permit monitoring data, which included data from the Southern California Stormwater Coalition Monitoring (SMC).
- County of San Diego MS4 NPDES permit monitoring data.
- Santa Margarita River Nutrient Initiative Group (SMRNIG) dataset from the water quality database developed for the *Hydrological and Biological Support to the Lower Santa Margarita Watershed Monitoring Program* final report (Stetson, 2010).
- California Environmental Data Exchange Network (CEDEN), which was a combined dataset from the United States Environmental Protection Agency (USEPA), Southern California Bight Program, SMC and Surface Water Ambient Monitoring Program (SWAMP) extracted from the CEDEN website.

- California Storm Water Multiple Applications and Report Tracking System (SMARTS) and California Integrated Water Quality System (CIWQS) Project databases were also reviewed to identify industrial and Publicly Owned Treatment Works (POTW) data. No relevant data and information were found in these databases.

The types of data and information that were obtained from these datasets generally included field measurements, field observations, photographs, site/field reconnaissance findings and mapping, water quality chemistry, bioassessment, toxicity, algal biomass and CRAM information. Where multiple datasets contained data from the same monitoring program (e.g. SMC), duplicates were removed from the compiled dataset.

Table 2-2. SMR WMA Receiving Water Data Sources- Raw Datasets

Data Source	Program	Period of Record	# of Locations	Data Type					
				Chemistry	Field Data	Observations/ Photographs	Biological	Toxicity	Physical Habitat
RCFCWCD	MS4 Permit	1993 – 2015	41	X	X	X	X	X	-

San Diego County	MS4 Permit	2008 - 2015	22	X	X	-	X	X	X

Note: Available data are indicated in the table by a "X.". Dashes indicate data were not available in the dataset for the given data type.

In addition to these programs, multiple special studies have been performed for areas within the SMR WMA. These studies provided additional information related to sources of nutrients in the watershed, contributions from other sources such as federal, state, and tribal lands, the effects of hydromodification on receiving waters, sediment toxicity, sources of iron and manganese in the watershed, the presence of trash in the watershed, and TMDL-related information. The special studies used in the prioritization process are shown in **Table 2-3**. Other studies used for evaluating sources are discussed in **Appendix 3A**.

Table 2-3. Other Types of Data Used for PWQC Identification [1]

Special Study Title	Type of Data	Notes
Eutrophication and Nutrient Cycling in Santa Margarita River Estuary: A Summary of Baseline Studies for Monitoring Order R9-2006-0076 (Estuary Data Report)	Algal biomass and percent cover, dissolved oxygen, total nitrogen and total phosphorus concentrations and fluxes between water and sediment.	---
Status of Eutrophication over a Two Year Period (2015-2016) in Lower Santa Margarita River, San Diego, California (SMRNIG Phase I Data Report)	Benthic algal abundance, benthic organic carbon, dissolved oxygen, pH, total nitrogen and total phosphorus concentrations, stream velocity, depth, discharge, channel substrate and riparian canopy cover.	Two year study in three portions of river.
Santa Margarita River Watershed Phase II-Sediment and Nutrient Calibration Memorandum	Results of Watershed Loading Model calibration for nitrogen and phosphorus.	---
Calibration of Linked Hydrodynamic and Water Quality Model for Santa Margarita Lagoon	Results of estuary model calibration for algae, dissolved oxygen, nitrogen and phosphorus.	---
Application of watershed loading and estuary water quality models to inform nutrient management in the Santa Margarita River Watershed.	Results of using the watershed loading model and estuary model to inform major science objectives for the SMRNIG, including understanding the major pathways that supply nutrients to the SMR Estuary, estimate the range of allowable loads to the SMR Estuary, evaluate potential numeric targets, identify preliminary scenarios for evaluating nutrient management, and estimate sources of nutrients to SMR Estuary.	---
Hydromodification Monitoring Project	Channel and bank conditions (gradient, particle size, channel width), location of discharge points, habitat integrity (individual CRAM attribute scores and selected parameters from SWAMP stream physical habitat characterization), quantification of bank eroded areas, and vertical and lateral susceptibility ratings.	Three monitoring locations.

Special Study Title	Type of Data	Notes
Sediment Toxicity Special Study, Santa Margarita Region, 2013-2014 Final Report	Analytical results for particle size, general chemistry, trace metals, organochlorine pesticides, and synthetic pyrethroids. Acute and chronic solid phase toxicity bioassay results, rapid stream bioassessment results (including IBI scores for four reaches).	---
Transitional Monitoring and Assessment Program Report for the Santa Margarita River Watershed Management Area (2014 - 2015)	Dry and wet weather receiving water trends.	One monitoring location

1. Pesticides Subcommittee Annual Report and Effectiveness Assessment 2014-2015 contains qualitative updates regarding short-term and long-term pesticide management efforts and concerns that are not immediately relevant to the assessment of receiving water conditions.

2.2.1 Assessment Areas

All available data were compiled and reviewed to conduct this assessment. Based on the data review, virtually no water quality data were identified to support the evaluation of the Upper SMR subwatershed, which is comprised of a total of 15 subareas. Where available, data for the Upper SMR Subwatershed are included in the tables in Sections 2 and 3.

As described in Section 1.3, the Upper SMR subwatershed has much lower population density and limited infrastructure relative to the Middle SMR subwatershed, and is hydrologically disconnected from the Middle and Lower SMR subwatersheds in all but very large storm events or storm series. Due to the lack of water quality data, very few documented water quality concerns, the absence of impaired beneficial uses in the lakes, and the hydrologic disconnection from the downstream subwatersheds created by the lakes, the Upper SMR subwatershed could not be fully evaluated using the process described in Sections 2.3 – 2.6 and Section 3. In particular, although there are 303(d) listings for Temecula Creek (Step 1A), the data used to support the listings were collected downstream from Vail Lake, and there are no data documenting exceedances within this subwatershed; so Step 1B of the process could not be completed. There were also no available data regarding erosional or other adverse impacts to receiving waters, and Step 2 could not be completed. In addition, data were not available from the Upper SMR Subwatershed to characterize discharges or potential impacts from developed areas, so Step 3 could not be completed.

Therefore, although the Upper SMR Subwatershed was characterized and evaluated, there were insufficient recent data to assign PWQCs and/or HPWQCs. However, a new Receiving Water Monitoring Site has been identified upstream of Vail Lake and monitoring will be conducted as specified in Section 5. As part of the WQIP adaptive management process, further evaluation of this subwatershed area will be conducted in the future as more data become available and in consideration of any new receiving water conditions of concern, and this WQIP will be updated accordingly. Although PWQCs and HPWQCs were not identified for the Upper SMR Subwatershed in this evaluation, the strategies identified in Section 4 will be implemented as applicable in the Upper SMR Subwatershed and as described in the JRMPs to ensure any potential water quality impacts are avoided.

The three subwatersheds of the SMR WMA are comprised of the 28 hydrologic subareas listed in Table 2-4 and shown in Figure 2-3. This delineation was based on a combination of watershed hydrologic subareas and the 2010 Clean Water Act Section 303(d)/305(b) Integrated Report (**Figure 2-3** and **Table 2-4**).

Table 2-4. Subareas in the SMR Subwatersheds

Upper SMR Subwatershed	Middle SMR Subwatershed	Lower SMR Subwatershed
Chihuahua Creek	Upper Murrieta Creek and Tributaries	Upper Santa Margarita River
Rattlesnake Creek-Temecula Creek	Warm Springs	Lower Santa Margarita River
Tule Creek	Murrieta and Long Canyon Creeks	Rainbow Creek
Long Canyon	Santa Gertrudis Creek	Sandia Creek

Cottonwood Creek-Temecula Creek	Temecula Creek and Redhawk Channel	De Luz Creek
Upper Cahuilla Creek	Pechanga Creek	Fallbrook Creek
Lower Cahuilla Creek		Santa Margarita River Estuary
Upper Wilson Creek		
Lower Wilson Creek		
Arroyo Seco Creek		
Rawson Canyon		
Upper Tucalota Creek		
Temecula Creek		
Warm Springs Creek		
Lower Tucalota Creek		

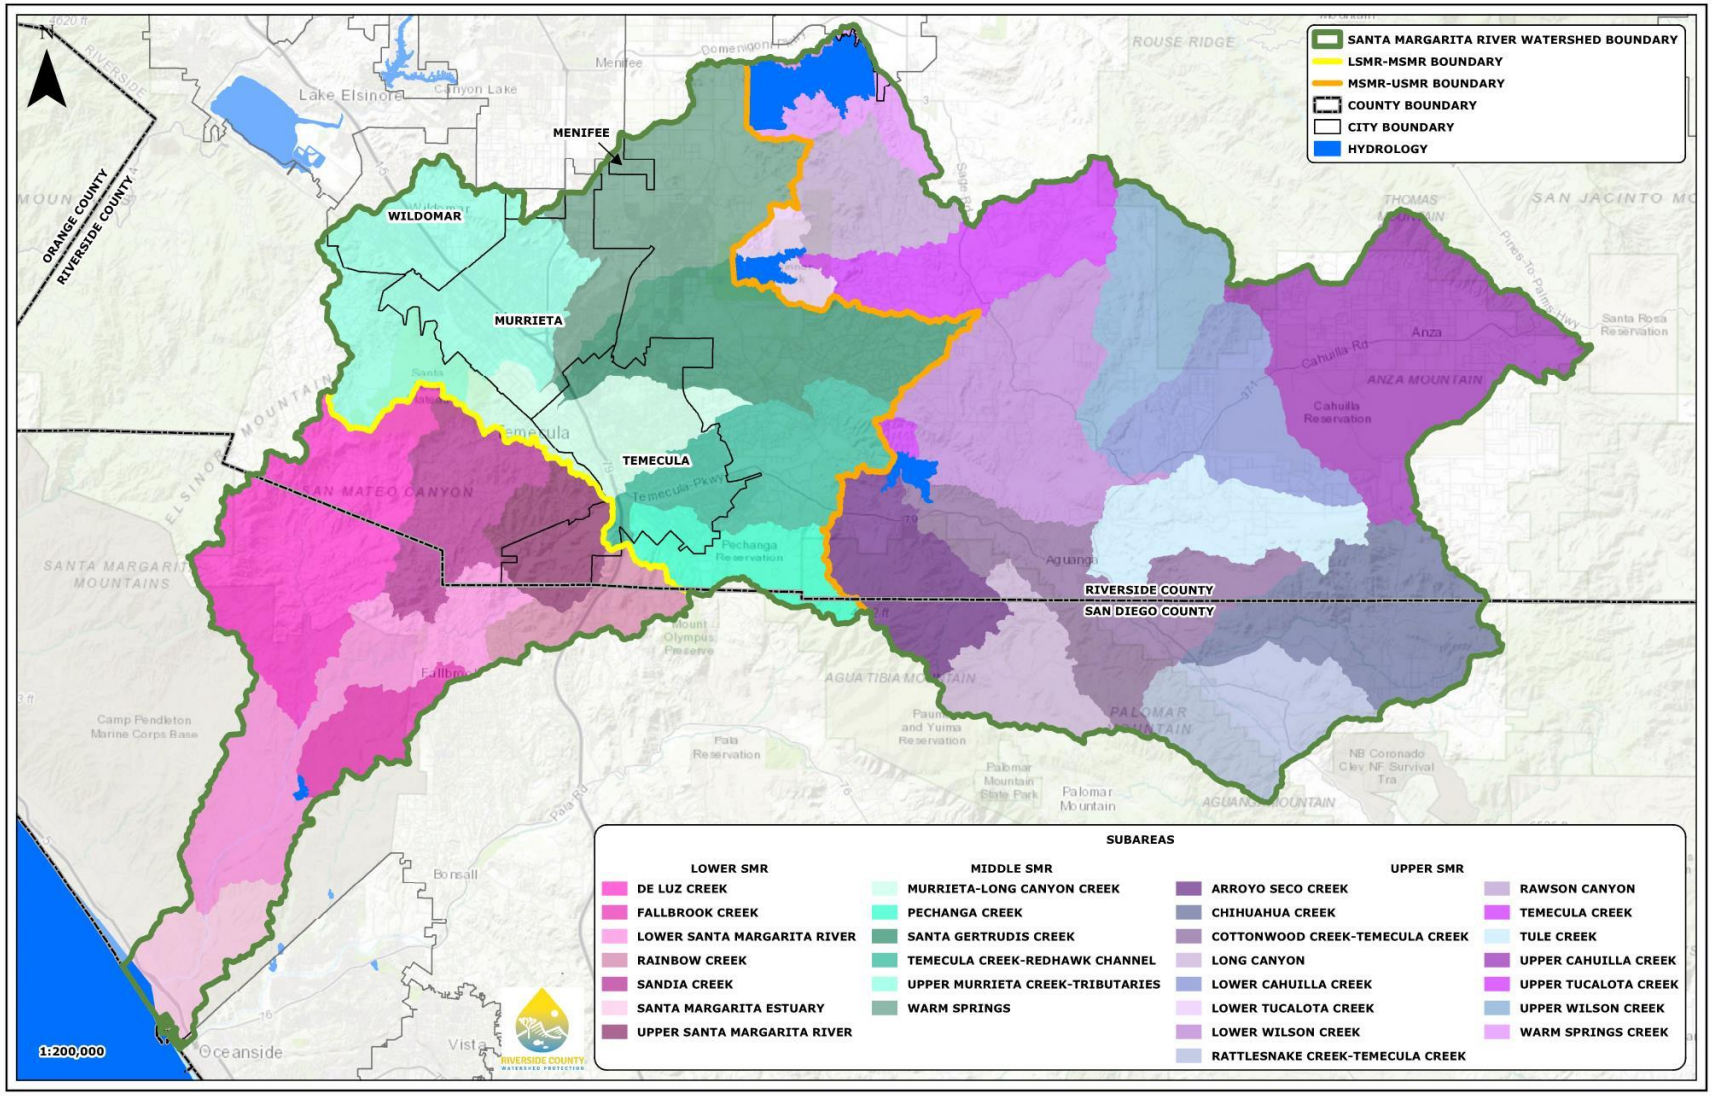

Figure 2-3. Priority Condition Assessment Subareas

2.2.2 Beneficial Uses and Thresholds to Assess Data

Beneficial uses for the SMR WMA are designated in the Water Quality Control Plan for the San Diego Basin (Basin Plan) (California Regional Water Quality Control Board, 1994 as amended in 2016). Per the Basin Plan, "Beneficial uses are defined as the uses of water necessary for the survival or well being of man, plants and wildlife." The designated beneficial uses for the SMR WMA are summarized in **Appendix 2**. Beneficial uses for Diamond Valley Lake, Lake Skinner, and Vail Lake are also described in Section 1.3, above. Per the Basin Plan:

"Existing beneficial uses were originally determined as part of a use survey of water resources in the Region described in Chapter 1, History of Basin Planning in the San Diego Region. Beneficial use designations have also been determined using additional information gathered since 1975. Beneficial uses are designated as "potential" for a variety of reasons, including:

- Plans are proposed to put the water to a future use;
- Potential exists to put the water to a future use;
- The public desires to put the water to future use;
- The water is potentially suitable for municipal or domestic water supply under the terms of the Sources of Drinking Water Policy (State Board Resolution No. 88-63); or
- The Regional Board has designated a beneficial use as a regional water quality goal."

Designated beneficial uses can only be modified through a use attainability analysis that meets the requirements of Title 40 of the Code of Federal Regulations (CFR) 131.10(g).

The WQIP is designed to support protection of the thirteen designated beneficial uses in the SMR WMA. Many of these beneficial uses have overlapping or related pollutants, stressors, and conditions that could be pollutants of concern. To streamline the analysis and aid in identifying PWQCs, the thirteen designated beneficial uses were grouped into five beneficial use categories (shown in **Table 2-5**). The groupings provide an organized framework for the large amount of data that is included in the analysis and focus the analysis on beneficial use impacts. The beneficial use categories do not represent Basin Plan designated beneficial uses. The assessments conducted in Steps 1 through 3 are all organized around these five beneficial use categories.

Based on the review of the available data summarized above, physical, chemical and biological indicators were identified that could be used to assess impacts to the beneficial use categories in the Subwatersheds. For each of these indicators, thresholds developed to protect beneficial uses were identified. Water quality objectives (WQOs) were used as the threshold where available, but WQOs do not exist for all identified chemical, physical, and biological indicators. For indicators without WQOs, thresholds were identified from available literature and guidance. The WQOs used for the assessment are included in **Appendix 2**. Other identified thresholds are discussed in **Section 2.3.2** in the summary of the assessment process for the indicator.

The beneficial use category, associated beneficial uses, and associated physical, chemical and biological indicators used to assess the potential impact on the beneficial uses are shown in **Table 2-5**. The assessments conducted to develop PWQCs are based on these beneficial use categories and indicators. Per the Basin Plan, "Designated beneficial uses are generally, but not always, present throughout the entire reach of a particular hydrologic unit, area, subarea, or water body.

Designated beneficial uses may not be present throughout the year." However, the Regional Water Board has noted that there are no seasonal variations identified in the designated surface waters (which includes the unlisted tributaries to these surface waters) in the Basin Plan tables. As a result, the assessments were conducted for all receiving water conditions, even though surface waters may not be present year-round.

Table 2-5. Beneficial Uses and Associated Physical, Chemical, and Biological Indicators Within the Santa Margarita River WMA

Beneficial Use Category [4]	Beneficial Uses	Physical, Chemical, and Biological Indicators
Aquatic Life	WARM COLD WILD RARE BIOL (limited) SPWN (limited)	Algal biomass Benthic community indices (IBI/CSCI) Dissolved Oxygen Total Nitrogen Total Phosphorus Ammonia Pesticides [1] Metals [2] Toxicity Sediment – visual observations [5] Physical habitat scores (CRAM) Evidence of erosion and hydromodification Trash
Recreation	REC-1 REC-2	Trash Fecal Coliform *E. coli*
Water Supply	MUN GWR	Nitrate Title 22 Constituents[3]
Agricultural Supply	AGR	Total Dissolved Solids Chloride Boron
Industry	IND PROC	pH Total Dissolved Solids

1. Pesticides include: Organophosphorus, Organochlorine, and Pyrethroid pesticides.
2. Metals include: Copper, Nickel, Zinc, and Selenium.
3. A full list of the California Code of Regulations Title 22 (Title 22) Constituents is included in **Appendix 2**.
4. Beneficial use categories were developed to group related designated beneficial uses from the Basin Plan for ease of assessment in the Water Quality Improvement Plan. Beneficial use categories are not designated in the Basin Plan.
5. Visual observations provided by Consultation Committee.

2.3 ASSESSMENT OF RECEIVING WATER CONDITIONS

The assessment of receiving water conditions consisted of two steps. Step 1 identified all constituents that could potentially impact beneficial uses. The identification was completed by summarizing constituents on the 303(d) list and identified in TMDLs or TMDLs under development that are causing impairments (Step 1A), comparing chemical data to WQOs to identify other pollutants with the potential to impair waterbodies (Step 1B), assessing known historic conditions and identifying if conditions are of potential concern based on more recent data by evaluating trends (Step 1B), and reviewing regulatory actions to determine if any other constituents have been identified as a priority by Regional or State Water Boards (Step 1C).

Step 2 identifies potential beneficial use impacts through a comparison of physical and biological data to identified thresholds.

2.3.1 Step 1. Identify Pollutants and Stressors of Potential Concern in Receiving Waters

2.3.1.1 Step 1A. Impaired Receiving Waters - 303(d) Listings (Permit Provision B.2.a(1))

In this step, the Copermittees identified constituent/water body combinations that are on the 303(d) list that could be considered pollutants or stressors of potential concern in receiving waters.

The Clean Water Act Section 303(d)/305(b) Integrated Report (Integrated Report) identifies the condition of the region's surface waters as well as the water quality limited segments that are identified as "impaired" or "threatened" (the 303(d) list). In California, water bodies are assessed and listed consistent with the State Water Board's Listing Policy. (California State Water Resources Control Board, 2004)

The receiving waters in the SMR WMA listed as impaired in the 2010 Integrated Report are summarized in **Table 2-6**. The 2010 Integrated Report is currently being updated. A proposed 2014/2016 list of impaired waters was approved by the State Water Board on October 3, 2017, but has not yet been approved by USEPA. Because the proposed listings are not yet effective, they have not been included within **Table 2-6**. However, the Step 1B assessment includes a review of the data used for the development of the 2014/2016 list to identify additional constituents that may be contributing to impairments based on data collected since the 2010 303(d) list and the State Water Board approved list was considered in the identification of PWQCs.

Table 2-6. 2010 303 (d) Listings for the SMR WMA

	Water Body [3]												
	Upper Santa Margarita River Subwatershed	Middle Santa Margarita River Subwatershed						Lower Santa Margarita River Subwatershed

1. Both reaches are within the Murrieta and Long Canyon Creeks subarea.
2. Both reaches are within the Temecula Creek and Redhawk Channel subarea. Listed extent of Temecula Creek lies within the Temecula Creek-Redhawk Channel, Cottonwood Creek-Temecula Creek, and Rattlesnake Creek-Temecula Creek subareas.
3. There are no 303(d) listed waterbodies in the Pechanga Creek subarea in the Middle SMR Subwatershed; Fallbrook Creek subarea in the Middle SMR Subwatershed; or in the Chihuahua Creek, Tule Creek, Long Canyon, Upper Cahuilla Creek, Lower Cahuilla Creek, Upper Wilson Creek, Lower Wilson Creek, Arroyo Seco Creek, Rawson Canyon, Upper Tucalota Creek, Temecula Creek, Warm Springs Creek or Lower Tucalota Creek subareas in the Upper SMR Subwatershed. There are no 303(d) listings for Vail Lake, Lake Skinner, or Diamond Valley Lake.
4. X – Currently being addressed by a TMDL.
5. XX – Currently being addressed by development of a TMDL Alternative project.

2.3.1.2 Step 1A. TMDLs

In this step, the Copermittees identified TMDLs that have been adopted or are under development.

2.3.1.2.1 Adopted TMDLs

The only adopted TMDL in the SMR WMA is the Rainbow Creek Nutrient TMDL (Basin Plan Amendment: Resolution No. R9-2005-0036), which became effective in 2006 (San Diego RWQCB, 2006). The TMDL includes targets and allocations to address nitrogen and phosphorus 303(d) listings in Rainbow Creek. In 2013, the TMDL was incorporated into Attachment E.3 of the Permit. The County of San Diego is the only Copermittee subject to this TMDL.

2.3.1.2.2 SMR Estuary TMDL Alternative

In 2011, a diverse group of stakeholders (cities and counties, utility districts, Caltrans, scientists, tribes, environmental groups, USGS, Camp Pendleton, Farm Bureau, Regional Water Board staff) formed the SMRNIG with the goal of addressing eutrophic, nitrogen and/or phosphorus 303(d) listings in the SMR WMA. The multi-year process will address the 303(d) listings in four reaches: SMR Estuary, Lower Santa Margarita River to confluence with De Luz Creek, Upper Santa Margarita River, and the Tributaries to the Santa Margarita River (hereafter called the Upper SMR Subwatershed[7]). The Regional Water Board is currently planning to formalize the regulatory requirements for the TMDL Alternative for the SMR Estuary by the end of 2018. The work that has been completed to date is summarized below. The listings in the remaining portions of the watershed will be addressed as funding is available.

The SMRNIG received two Proposition 84 grants to conduct studies and analyses to support the development of a TMDL Alternative for the watershed.

1. The first grant covered data analysis in the SMR Estuary to identify potential targets as well as monitoring in the SMR below the confluence with De Luz Creek.
2. The second grant covered the data analysis for the river monitoring conducted under the first grant as well as monitoring of the remainder of the SMR and tributaries.

The results of the monitoring and data analysis are summarized in two reports:

1. *Eutrophication and Nutrient Cycling in Santa Margarita River Estuary: A Summary of Baseline Studies for Monitoring Order R9-2006-0076* (Estuary Data Report)*;* and
2. *Status of Eutrophication over a Two Year Period (2015-2016) in Lower Santa Margarita River, San Diego, California* (SMRNIG Phase I Data Report).

The major findings of the reports were that the SMR Estuary is "exhibiting symptoms of eutrophication, as documented by high biomass and cover of macroalgae and episodes of low dissolved oxygen." Additionally, high dry weather concentrations of nutrients in the SMR Estuary indicate the presence of anthropogenic sources of nutrients. Findings from the SMRNIG Phase I Data Report identified significant variations in concentrations depending on the season for all parameters measured. The majority of the nitrogen and phosphorus observed results were below Basin Plan WQOs. The monitoring showed some periods of low DO in the summer. Higher algal biomass was observed in 2015 as compared to 2016 when concentrations were similar to reference conditions. The results of the studies identified that eutrophication is a concern in the SMR Estuary

[7] For the purpose of this TMDL Program the "Upper SMR Subwatershed" refers to both the Upper and Middle subwatershed areas as defined under the WQIP.

and nutrient loading from the watershed is contributing to the eutrophication in the Estuary. Results are less clear in the Lower SMR and eutrophication was not identified in the river as part of the SMRNIG Phase I Data Report.

As part of the development of the TMDL Alternative for the SMR Estuary, the SMRNIG partner, Marine Base Camp Pendleton, sponsored Space and Naval Warfare Systems Command (SPAWAR) to develop an estuary model using monitoring data for total nitrogen, total phosphorus, algal biomass, and dissolved oxygen collected in 2008 and 2009 in the SMR Estuary. The Estuary model predicts the dissolved oxygen and algal biomass concentrations resulting from total nitrogen and total phosphorus loading to the SMR Estuary. Several model scenarios were run to assess the changes in dissolved oxygen and algal biomass concentrations predicted to result from reducing loadings of total nitrogen and total phosphorus to the SMR Estuary. The results of the model scenarios are summarized in the Model Application Report (Sutula, et al., 2016).

In addition to the Estuary model, a watershed loading model was developed by Tetra Tech on behalf of the Regional Water Board for the SMR Watershed. The purpose of this model was to predict the loadings from the watershed into the SMR Estuary and estimate the contributions from various land based sources (e.g. agricultural, open space, Caltrans, federal lands, and MS4s). The watershed loading model was only calibrated at the base of the watershed at the point of entry into the SMR Estuary. As a result, the loading estimates for areas upstream of the SMR Estuary are preliminary and will likely be refined as future phases are completed. The results of the watershed loading model are also presented in the Model Application Report.

The relevant findings for the WQIP development from the Model Application Report were as follows:

- Eutrophication is a dry weather concern in the SMR Estuary. Eutrophication symptoms are present during dry weather, and exhibit their peak during summer dry weather. Uncertainties exist regarding the impact of wet weather discharges on groundwater concentrations that could ultimately result in baseflows during dry weather.
- As configured in the Estuary model, major external sources of total nitrogen (TN) to the SMR Estuary during dry weather consist of surface water and local groundwater inputs, while major total phosphorus (TP) sources include surface water and upstream aquifer discharge, though many uncertainties exist in the estimates.
- Dissolved oxygen and macroalgal biomass and cover have demonstrated linkages to beneficial uses, have a predictive relationship with nutrient loading to the SMR Estuary, and have practical and generally cost-effective methods for measurement and interpretation of data. These two indicators seem to be well suited for further consideration as numeric targets for the SMR Estuary. Use of TN and TP targets is not recommended because ambient TN and TP concentrations do not have a strong linkage to beneficial use impairments.
- The watershed loading model provides a quantitative basis for summarizing the nutrient loads and sources for the SMR watershed, for the purpose of supporting nutrient management discussions. While tools for modeling watershed loading can be improved, the basic requirements for quantitative analysis are met.

While the Rainbow Creek Nutrient TMDL used a numeric interpretation of the narrative Basin Plan WQOs to derive TN and TP targets and associated allocations for various sources, the TMDL Alternative for the SMR Estuary is focused on reducing nutrient loading to the SMR Estuary to

prevent low dissolved oxygen and benthic community impacts that result from excess algal biomass, based on the findings in the Model Application Report. As a result, the TMDL Alternative for the SMR Estuary will likely have targets based on some combination of DO, algal biomass and benthic community scores rather than TN and TP concentrations. Then, necessary TN and TP load reductions to meet those targets in the SMR Estuary (based on the Estuary model scenarios) will be used to develop load and wasteload allocations based on the watershed loading model.

To facilitate this process, several technical memoranda have been prepared by the SMRNIG and provided to the Regional Water Board for consideration in the TMDL Alternative development. These technical memoranda, combined with the Model Application Report, were used to inform the selection of the PWQCs and to develop goals and strategies for the WQIP. Because the TMDL Alternative for the SMR Estuary is still under development, the information provided in the WQIP is subject to revision once the TMDL Alternative for the SMR Estuary is approved. Additionally, if future phases of the project are funded, relevant findings will be incorporated into the WQIP as part of the adaptive management process.

2.3.1.3 Step 1B. Evaluation of Receiving Water Limitation Exceedances and Comparison to Historical Conditions (Provisions B.2.a.(4) and B.2.A.(5))

To assess the receiving water quality conditions, Step 1B of the prioritization process included two types of analyses: 1) evaluation of exceedances of receiving water limitations and a comparison of the results to the 303(d) listings, TMDLs, and known historic conditions; and 2) historic data review and a trend analysis to compare current conditions to known historic conditions. The data used for the two assessments is described in the following section.

2.3.1.3.1 Data Used in the Assessment

The available raw data included samples from 1950 to 2015. All historic data was included in a qualitative review for an assessment of historic conditions. However, upon review of the full dataset, it became clear that data prior to 1998 was not collected with established Quality Assurance Project Plans (QAPPs) and, therefore, lacked sufficient data quality to be used in assessing the receiving waters (e.g., inconsistent methods, issues with reporting limits; discussed further in **Section 2.5.2**). Therefore, the time period from 1998 to 2015 was selected to perform the data evaluation and assess trends. For the evaluation of exceedances of receiving water limitations, data from 2005 to 2015 was selected to represent the current conditions because monitoring data during that time period reflects requirements from the two most recent MS4 NPDES permit cycles. Locations of the monitoring sites used for the assessment are shown in **Figure 2-4**.

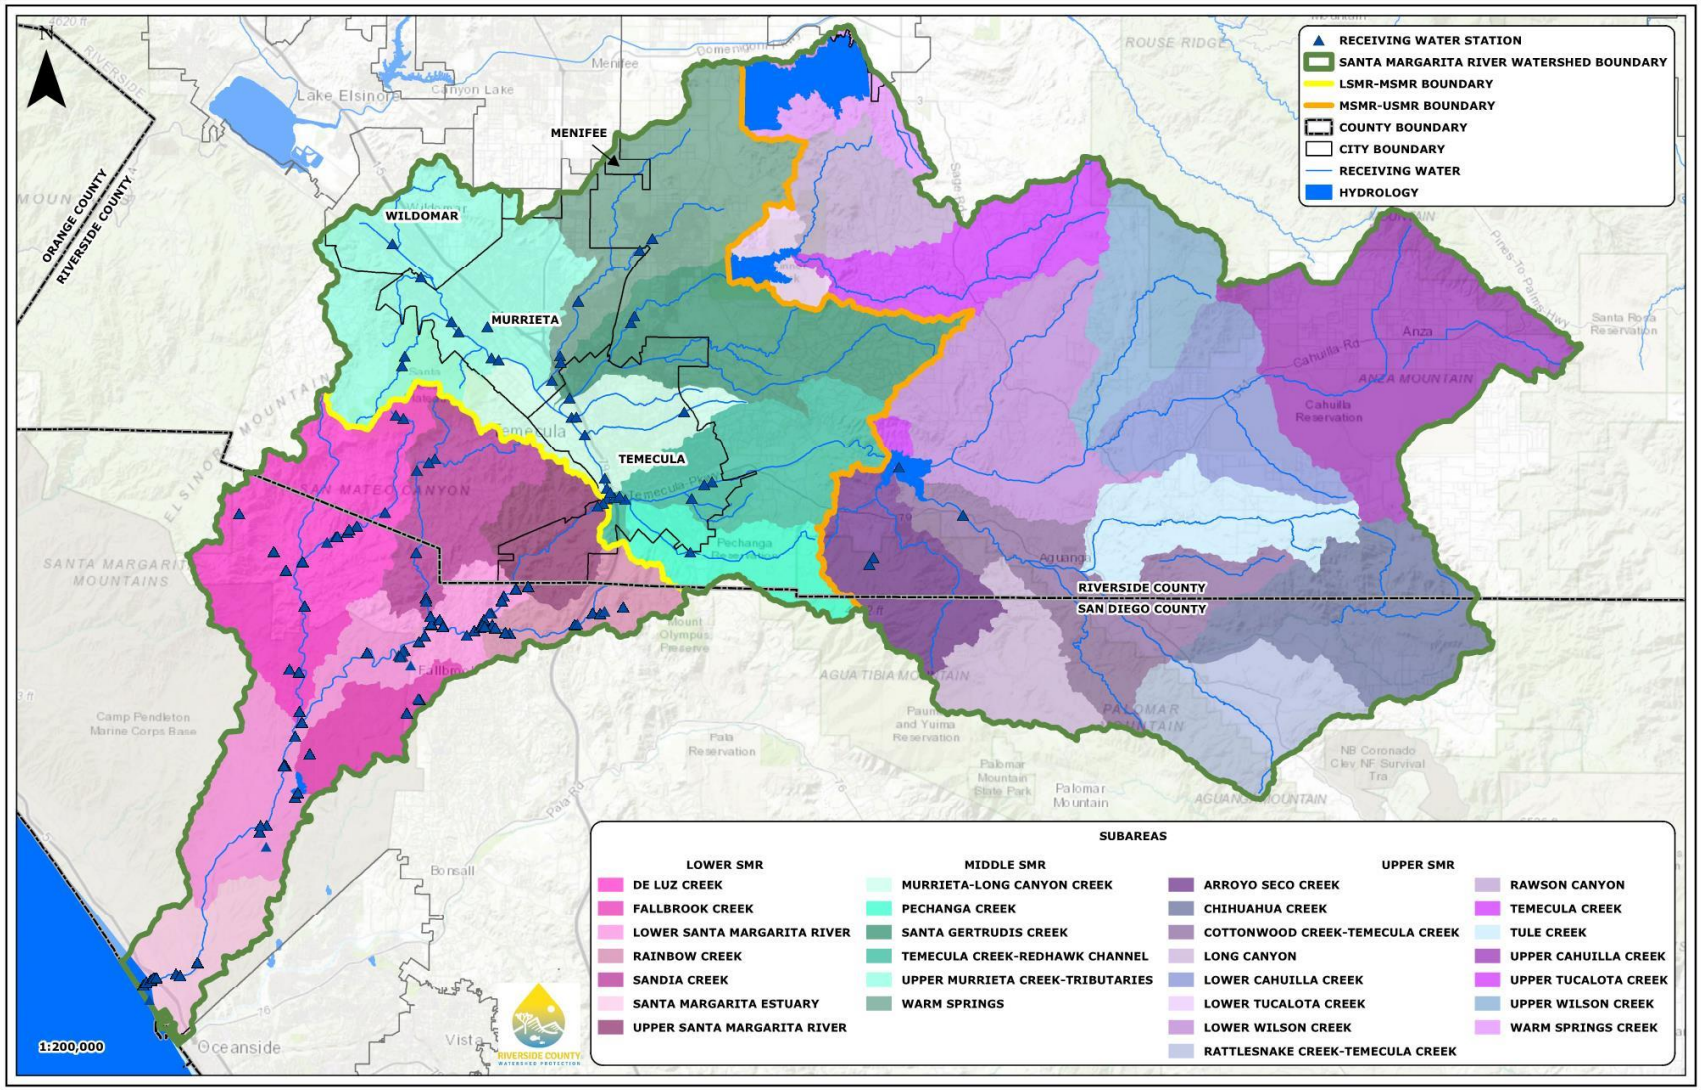

Figure 2-4. Historic Receiving Water Monitoring Stations Used in Assessment

2.3.1.3.2 Evaluation of Receiving Water Limitation Exceedances

The evaluation of receiving water limitation exceedances was conducted by comparing all constituents to applicable WQOs for the designated beneficial uses in the subarea. WQOs contained in the Basin Plan, California Toxics Rule (CTR), and the National Toxics Rule (NTR) identified as receiving water limitations in Permit Provisions A.2 and B.2 were compiled for the evaluation and are included in **Appendix 2**. The following approach was used to select the WQOs used for the exceedance evaluation. Where conflicting objectives were identified, the most conservative objective was chosen.

- For dry weather samples, the lowest applicable acute, chronic, or human health objective from either the CTR/NTR or the Basin Plan was used for the evaluation.
- For wet weather samples, the lowest acute objective between the CTR/NTR and the Basin Plan was selected. If there were no acute objectives, the CTR/NTR or Basin Plan WQOs with the shortest averaging period was selected.
- Reach-specific objectives apply for total dissolved solids (TDS), sulfate, chloride, and dissolved oxygen and were applied appropriately for the reach where the sample was collected.
- For WQOs that are calculated using pH, temperature or hardness, the pH, temperature and/or hardness of the sample was used to calculate the objective if available. If not available, the median value for all wet and/or dry samples was used to calculate the value of the objective.

For this evaluation, exceedances were defined as a subarea that has not met an applicable WQO in at least two samples and more than 10% of all samples in the subarea. The ≥10% threshold was used as it is an allowable exceedance frequency for objectives for biostimulatory substances, dissolved oxygen, and all constituents in Tables 3-2 in the Basin Plan and it approximates the thresholds used for evaluation in the State Water Board's Listing Policy[8] (California State Water Resources Control Board, 2004). **Figure 2-5** summarizes the constituents with current exceedances during dry and wet weather conditions. Constituents on the 303(d) list for the subarea are bolded and underlined in the figure.

In some cases, the exceedance analysis demonstrated that WQOs are no longer being exceeded for some constituents on the 303(d) list. While there were insufficient data to delist the constituents in most cases, the lack of recent exceedances, combined with a stable or decreasing trend analysis, was determined to be sufficient evidence that these constituents were likely no longer a pollutant of concern in receiving waters (e.g., chlorpyrifos).

[8] The Listing Policy uses a binomial distribution approach based on the number of samples that has a hypothesis that the actual exceedance proportion is between 10 and 25% for conventional pollutants and between 3 and 18% for toxicants. Ten percent was selected as a threshold for streamlined analysis that was on the lower end for conventional pollutants and in the range of the thresholds for toxic pollutants.

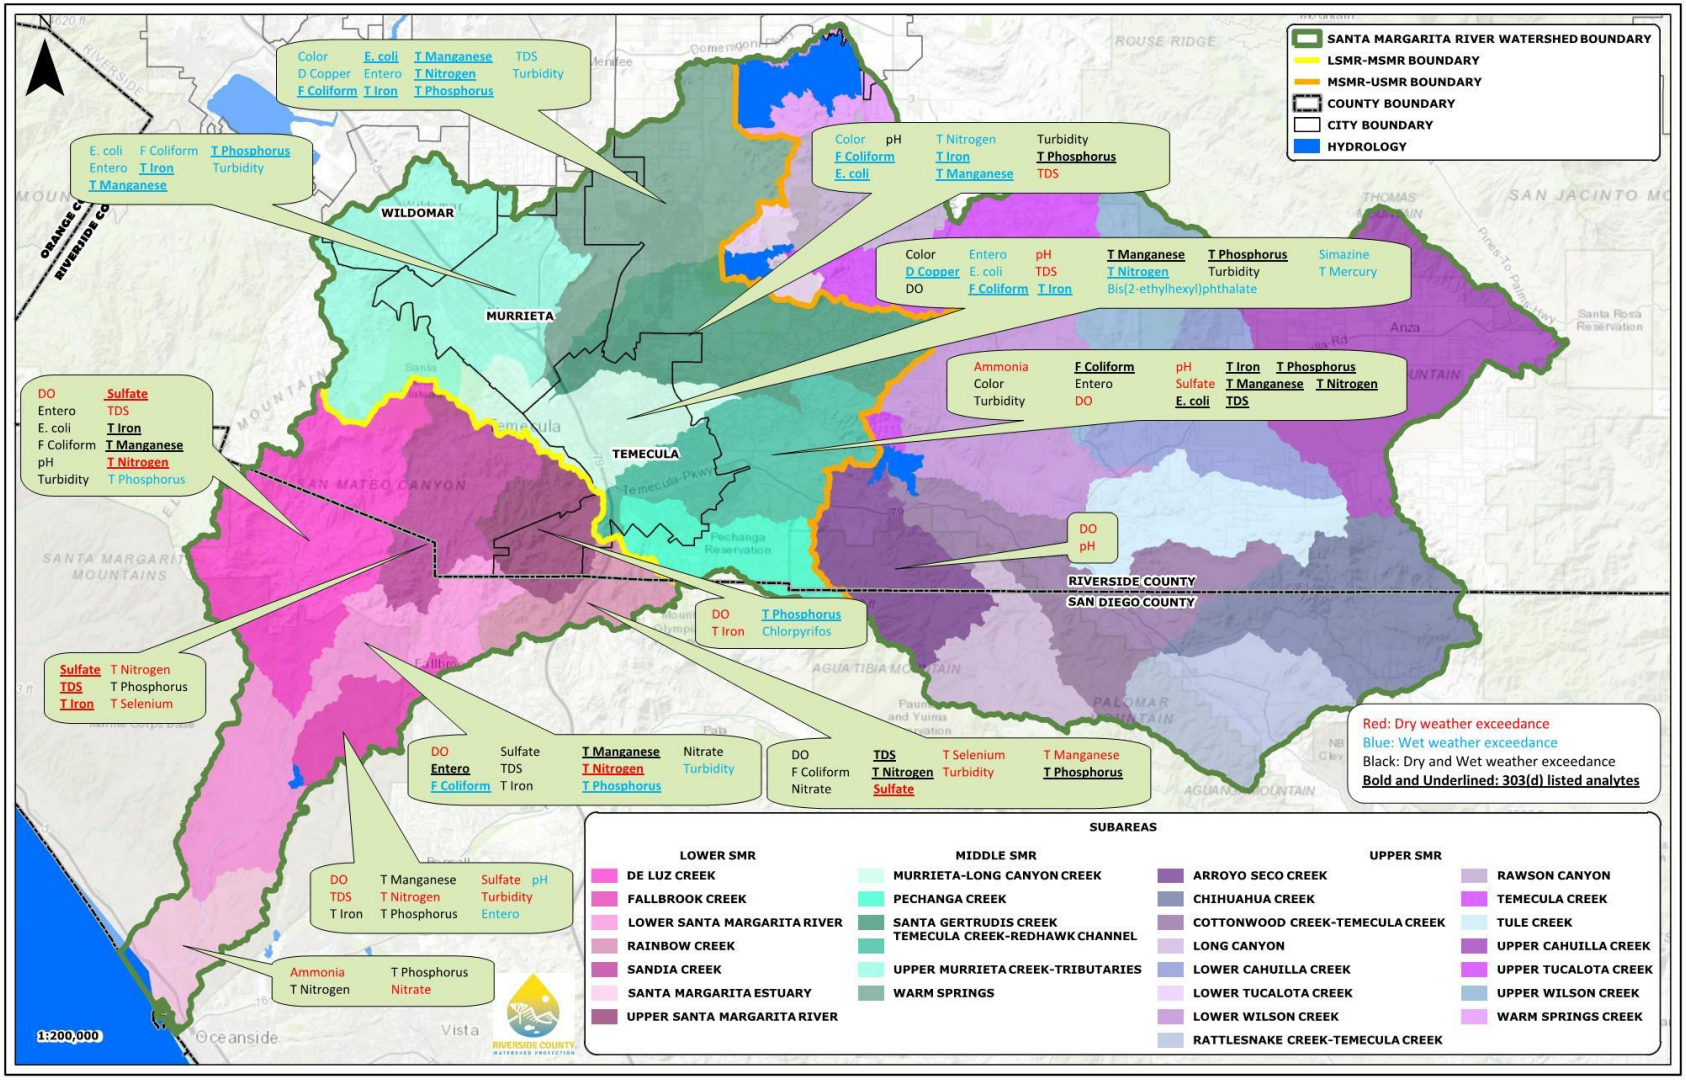

Figure 2-5. Water Quality Objective and Threshold Exceedances Identified in Receiving Waters (Recent Data: 2005 – 2015)

2.3.1.3.3 Comparison to Historical Conditions

Comparison of current data to known historic conditions was evaluated through a trends analysis.

For the Middle SMR Subwatershed, a trend analysis was conducted using data from 1998-2015, grouped by subarea, to assess whether the water quality indicator conditions were improving, declining, or stable. The trend analyses were conducted using the Mann-Kendall (M-K) test (Helsel, Hirsch, 2002). The M-K test is a simple but robust statistical method to find trends in datasets. The M-K test cannot assess trends for datasets with three or fewer samples.

The statistic of the M-K test (S) is computed by evaluating differences between all possible pairs of measurements in the dataset. An S value greater than zero indicates that the majority of later measurements are larger than the earlier ones, suggesting an upward trend over time. Similarly, a negative S value implies that earlier measurements are larger and the trend over time is decreasing. The decision for how the water quality of the receiving water is changing (or not) was made according to the rules shown in **Table 2-7** (Aziz, 2003):

Table 2-7. Trend Estimation Based on M-K Test Statistic (S) and Critical S Value ($S_{crit95\%}$)

Rule	Condition	Trend
1	$S > 0$ and $S > S_{crit\ 95\%}$	Declining
2	$S > 0$ and $S_{crit\ 90\%} < S < S_{crit\ 95\%}$	Probably Declining
3	$0 < S < S_{crit\ 90\%}$	No trend
4	$S \leq 0$, $\lvert S \rvert < S_{crit\ 90\%}$, and COV ≥ 1	No trend
5	$S \leq 0$, $\lvert S \rvert < S_{crit\ 90\%}$, and COV < 1	Stable
6	$S < 0$ and $S_{crit\ 90\%} < \lvert S \rvert < S_{crit\ 95\%}$	Probably Improving
7	$S < 0$ and $\lvert S \rvert > S_{crit\ 90\%}$	Improving

COV: Coefficient of variation

DO is the only exception to the stated rules, given that an increasing DO concentration results in an improving condition, and decreasing DO values are linked to a declining condition.

For the Lower SMR Subwatershed, due to readily available trends analysis from the recent SMR WMA Transitional Monitoring and Assessment (TMAR) Report (County of San Diego, 2016), the statistical analysis was not needed for the Lower SMR. The TMAR Report presented an analysis of receiving water trends using the historical dataset for the SMR-MLS-2 Long Term Monitoring Station (LTMS).

The trend analyses are presented in **Table 2-8** for wet weather and **Table 2-9** for dry weather. The detailed statistical results for the trend analysis for exceedances in the Middle SMR Subwatershed are included in **Appendix 2**.

↗ probably improving ↑ improving ↘ probably declining ↓ declining → stable NT no trend — no exceedance/no data
Reaches not included did not have any trends data available

Where sufficient data were available for the assessment and trends could be developed, the trend analysis demonstrates that most conditions in the Middle SMR Subwatershed appear to either show no trend or are trending towards improvement. The exceptions include some subareas where conditions are declining for TDS. For the Lower SMR Subwatershed, most trends were toward improvement with some declining trends for nitrogen, dissolved selenium, conductivity and surfactants.

2.3.1.4 Step 1C. Identify Significant Regulatory Actions

In Step 1C, Copermittees identified constituents that are subject to significant regulatory action (other than 303(d) listings and TMDLs, which are addressed in Step 1A). Constituents subject to significant regulatory actions were evaluated to determine if any other constituents have been identified as a priority by Regional or State Water Boards.

The Statewide Trash Amendments (California State Water Resources Control Board, 2015) constitute a significant regulatory action affecting all Copermittees with land use jurisdiction over designated priority land uses pursuant to the amendments. This includes all subareas in the Middle SMR Subwatershed, and the Fallbrook Creek subarea in the Lower SMR Subwatershed. The Upper SMR Subwatershed has not been evaluated regarding priority land uses pursuant to the amendments.

No other existing or proposed significant regulatory actions were identified.

2.3.1.5 Step 1 Results

Based on the Step 1A assessment of 303(d) listings and TMDLs, eutrophication, nitrogen, phosphorus, pesticides (chlorpyrifos and diazinon), metals (copper), toxicity, bacteria (*E. coli*, *Enterococcus*, fecal coliform), some Title 22 constituents (iron and manganese), Total Dissolved Solids, and sulfate were identified as pollutants and stressors of potential concern in receiving waters.

The Step 1B exceedance and trend analyses confirmed most of the Step 1A analysis and identified a few additional constituents in limited locations. The analysis also demonstrated that chlorpyrifos in the Middle SMR Subwatershed was no longer exceeding and should likely be delisted once sufficient samples are collected.

Step 1C resulted in the addition of trash for subareas with priority land uses to the list of pollutants and stressors of potential concern.

Table 2-10. Summary of Step 1 Results: Pollutants and Stressors of Potential Concern

Beneficial Use Category	Pollutants of Potential Concern in Receiving Waters
Aquatic Life	Eutrophication, nitrogen, phosphorus, chlorpyrifos, simazine, copper, selenium, toxicity, turbidity, trash
Recreation	Bacteria, trash
Water Supply	Nitrate, iron, manganese, Total Dissolved Solids, sulfate
Agricultural Supply	Total Dissolved Solids
Industrial Supply	Total Dissolved Solids, pH

2.3.2 Step 2. Identify PWQCs Potentially Impacting Beneficial Uses (Provisions B.2.a.(3), B.2.a.(6), B.2.a.(7), B.2.a.(8))

Based on the constituents identified in Step 1 as pollutants and stressors of potential concern in the receiving waters, Step 2 was completed to evaluate the potential impacts on beneficial uses from physical, chemical, and biological indicators and develop potential PWQCs. The evaluation consisted of the following:

- Assessing locations of known beneficial use impacts and sensitive receiving waters in the watershed.
- Evaluating biological and physical indicators using identified assessment thresholds (chemical factors were assessed in Step 1).
- Incorporating the results from Step 1 for the chemical indicators to identify potential PWQCs by beneficial use category.

2.3.2.1 Location of Known Beneficial Use Impacts and Sensitive Receiving Waters

For each subarea, a series of questions related to the beneficial use categories were used to evaluate where beneficial uses may be impacted as a result of the physical, chemical, and biological indicators identified in **Table 2-12**. The questions included the following:

Aquatic Life: Are sensitive areas present that could be impacted?

Recreation: Are there areas of known contact recreation and are flow conditions supportive of contact recreation (REC-1)?

Municipal Supply: Are there any known municipal supply diversions?

Agricultural Supply: Are there any known agricultural supply diversions?

Industrial Supply: Are there any known industrial diversions?

Table 2-11 and the text below provides a summary of this analysis, which was conducted in order to elevate water bodies recognized as sensitive or highly valued to potential priority areas. Sensitive receiving waters in the Middle SMR Subwatershed include streams with the Preservation of Biological Habitats of Special Significance (BIOL) designated beneficial use and bodies of water recognized as wetlands by the State or U.S. Fish and Wildlife Service's National Wetland Inventory (NWI) (www.fws.gov/wetlands/). The Upper and Lower SMR Subwatersheds do not include any BIOL designated waterbodies but do include NWI recognized waterbodies. Sensitive water bodies in the Middle and Lower SMR Subwatersheds are identified in **Figure 2-6**.

Known locations of contact recreation beneficial uses were identified in the Murrieta Creek and Long Canyon subarea and all subareas of the Lower SMR Subwatershed. Flow conditions to support contact recreation were identified in the Warm Springs, Murrieta Creek and Long Canyon, Santa Gertrudis Creek subareas and all subareas of the Lower SMR Subwatershed.

Known municipal diversions were identified in the Lower SMR subarea. Known agricultural diversions were identified in Sandia Creek and the De Luz Creek subareas. No known industrial diversions were identified in any subarea. Active diversions in the watershed are included in **Appendix 2**.

Table 2-11. Beneficial Use Associated Questions

Subwatershed	Subarea	Aquatic Life: Sensitive Areas Potentially Impacted?	REC: Location of Known Recreation?	REC: Flow Conditions Supportive of Recreation?	MUN: Location of Known Municipal Supply Diversion?	AGR: Location of Known Agricultural Supply Diversion?	IND: Location of Known Industrial Diversion?
Upper SMR	Arroyo Seco Creek	No	No	No	No	No	No

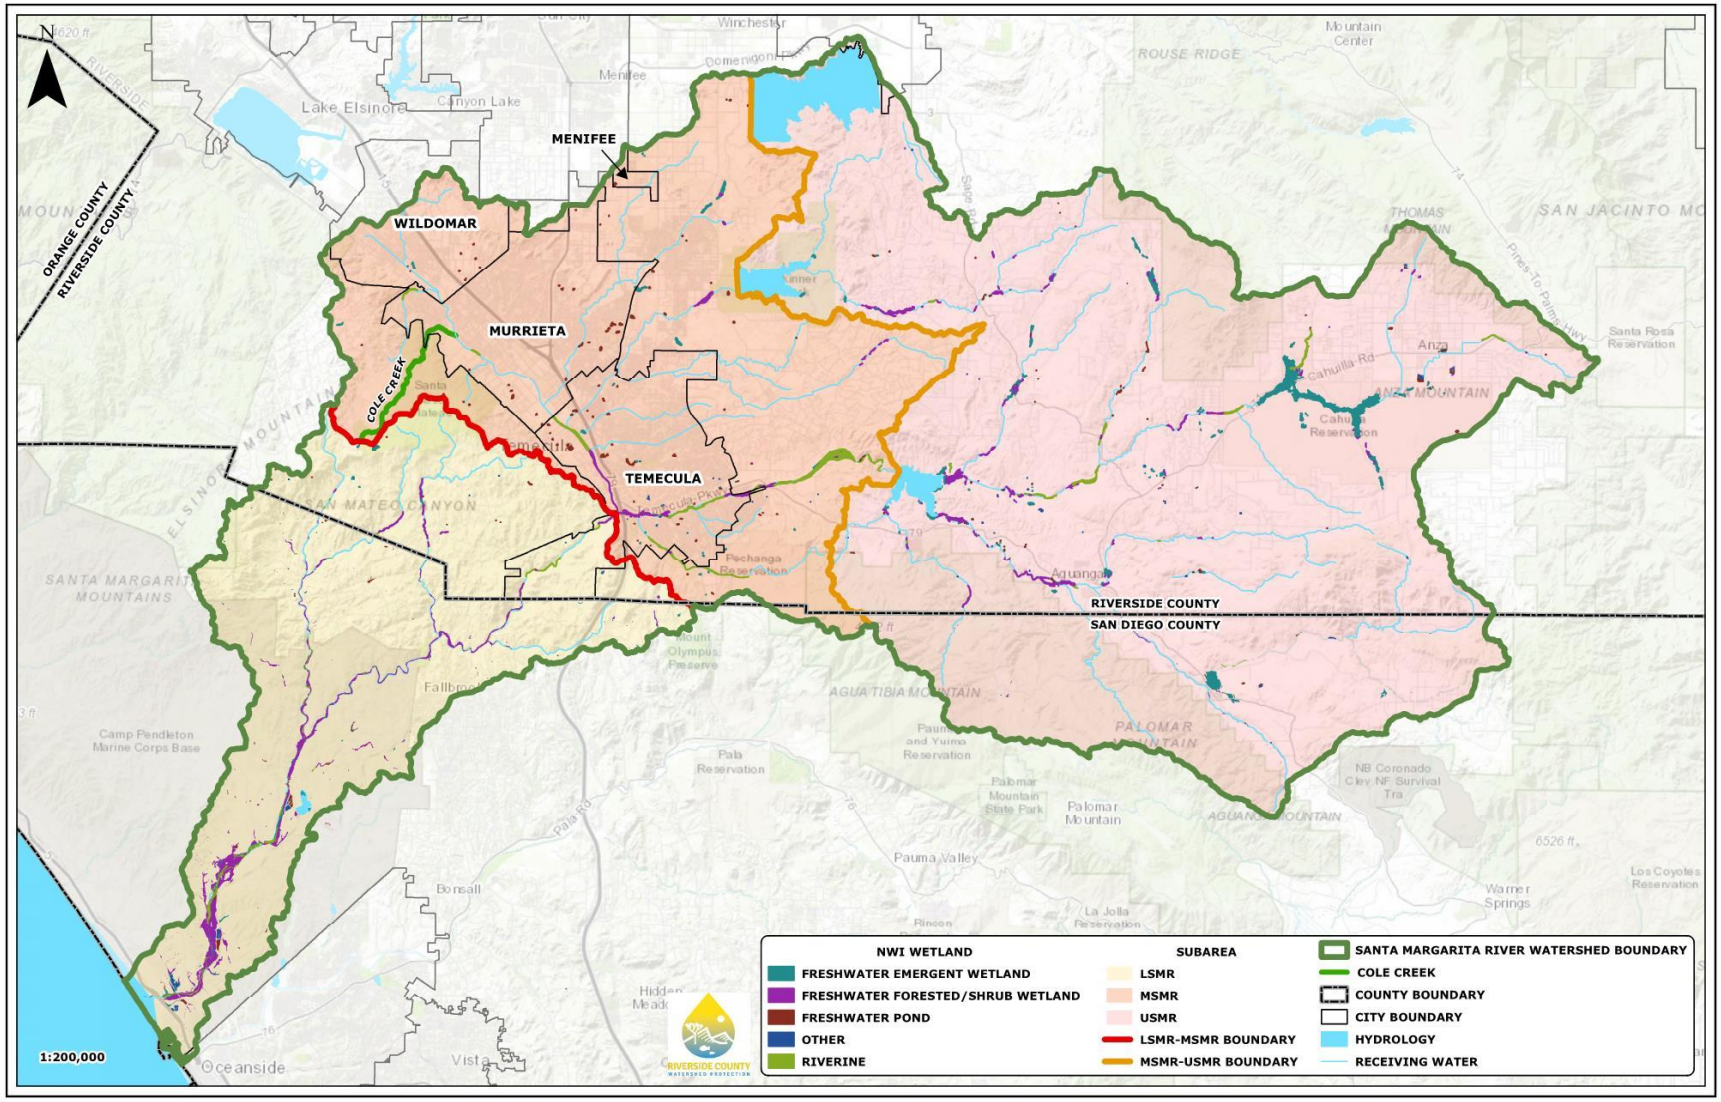

Figure 2-6. SMR Sensitive Waters – Wetlands Designated by the NWI and Cole Creek (with BIOL Beneficial Use)

2.3.2.2 Step 2A. Biological and Physical Indicator Assessment

As discussed in **Section 2.2.2**, the beneficial uses in the SMR WMA were grouped into a number of beneficial use categories. In addition to the chemical data assessed in Step 1, some beneficial use categories are potentially impacted by physical and biological indicators. The physical and biological indicators assessed are summarized in **Table 2-12**. Only the aquatic life and recreation beneficial use categories had associated physical and biological indicators that were evaluated in this step.

Table 2-12. Beneficial Uses and Associated Physical and Biological Indicators Within the Santa Margarita River WMA

Beneficial Use Category	Beneficial Uses	Physical, Chemical, and Biological Indicators
Aquatic Life	WARM COLD WILD RARE BIOL (limited) SPWN (limited)	Algal biomass Benthic community indices Physical habitat scores (CRAM) Evidence of erosion and hydromodification Trash
Recreation	REC-1 REC-2	Trash

2.3.2.2.1 Algal Biomass Assessment

No WQOs or established thresholds are available for algal biomass. In the early 2000s, the State Water Board began a process for establishing a biostimulatory policy. As part of that process, they developed an initial assessment of potential thresholds that included benthic algal biomass. (Tetra Tech, 2006) The metrics presented in **Table 2-13** were developed for freshwater streams and are indicative of three beneficial use risk categories. Category I is considered presumptively unimpaired (use is supported), Category II is considered potentially impaired, and Category III is considered presumptively impaired (use is not supported or is highly threatened). While the science being used to develop the State Water Board's biostimulatory policy is still evolving, the thresholds developed as part of this initial effort have been used in TMDL development in Southern California and represent the best available information for determining thresholds for algal biomass at this time.

Table 2-13. Benthic Algal Biomass Thresholds for SMR WMA Beneficial Uses (Tetra Tech, 2006)

Beneficial Use Risk Category [2]	Benthic Algal Biomass In Streams (mg chl-a/m^2)		
	Beneficial Use[1]		
	COLD	WARM	SPWN
I/II	100	150	100
II/III (maximum)	150	200	150

1. Although the 2006 TetraTech Report included additional beneficial uses, only the beneficial uses presented are applicable to reaches in the Santa Margarita River Watershed.
2. Thresholds shown are the break point between the two beneficial use risk categories.

The benthic algal biomass chlorophyll-a concentrations observed within the SMR watershed were compared to a threshold of 150 milligram per cubic meter (mg/m^2). This threshold was selected as it represents an unimpaired condition for the WARM beneficial use, which applies to all waters in the WMA, and is the maximum threshold for the COLD beneficial use under the cited framework. It is also consistent with the numeric targets for TMDLs for similar watersheds with both WARM and COLD beneficial uses (Malibu Creek and Ventura River). Chlorophyll-a data for SMR WMA are shown in **Table 2-14**. In the Middle SMR Subwatershed, data from 2005 to 2015 were obtained from the SMC dataset and the annual reports. In the Lower SMR Subwatershed, data from 2008 to 2015 were obtained from the SMC and SWAMP datasets. Results exceeding 150 mg/m^2 were considered indicative of eutrophic conditions.

Table 2-14. Chlorophyll-a Concentrations Observed Within the SMR WMA During Dry Weather

Subwatershed	Subareas	Reach Name	Chlorophyll-a (mg/m^2)
Upper SMR	Arroyo Seco Creek	Arroyo Seco Creek	9
Middle SMR	Upper Murrieta Creek and Tributaries	Slaughterhouse Canyon	48
		Cole Canyon	122
	Warm Springs	Warm Springs Creek	43
		French Valley	**179**
	Santa Gertrudis Creek	Tucalota Creek	85
	Murrieta and Long Canyon Creek	Murrieta Creek	49
	Temecula Creek and Redhawk Channel	Redhawk Channel	**2300**
		Temecula Creek	85
Lower SMR	Upper Santa Margarita River	Santa Margarita River	125
	Lower Santa Margarita River	Santa Margarita River	23
	Rainbow Creek	Rainbow Creek	-
	Fallbrook Creek	Fallbrook Creek	-
	De Luz Creek	Adobe Creek	111
	Sandia Creek	Sandia Canyon Creek	72
		Sandia Canyon	4

BOLDED values exceed the identified threshold of 150 mg/m2 and were considered indicative of eutrophic conditions
A dash means no data available

Elevated algal biomass concentrations were only observed in two subareas, indicating potential eutrophication conditions.

2.3.2.2.2 Benthic Macroinvertebrate Assessment

Benthic macroinvertebrate community condition is assessed using the California Stream Condition Index (CSCI) and the Benthic Macro-Invertebrate (BMI) index of biotic integrity (IBI). The BMI IBI is a multi-metric index developed specific to Southern California and is used to evaluate the conditions of the benthic macro-invertebrate community structure (Ode, et al., 2005). This metric has been calculated at various monitoring locations in the watershed based on bioassessment data.

The BMI IBI score is calculated based on several metrics including taxa richness, EPT[9] taxa, percent intolerant individuals, percent tolerant taxa, and percent collector filterers and collector gatherers. In addition, the CSCI is used throughout the state in a similar fashion and may be available for some or all sites. Because water quality objectives are not currently available for IBI and CSCI results, thresholds were developed for the assessment based on literature values as shown in **Table 2-15**.

Table 2-15. Thresholds Associated with Benthic Macro-Invertebrate Index of Biotic Integrity and California Stream Conditions Index Scores

Threshold	IBI Score[1]	CSCI Score[1]
Very High	56 – 70	≥ 0.92
Good	41 – 55	0.79 – 0.91
Moderate	27 – 40	0.63 – 0.78
Low	14 – 26	0 – 0.63
Very Low	0 - 13	

1. Weston, 2015.

Subareas were considered to be potentially impacted if CSCI < 0.78 or IBI < 40 (i.e., very low, low, or moderate thresholds). In cases where both CSCI and IBI data were available, the CSCI data were used in the assessment as this index represents the latest science and assessment methodology for benthic macroinvertebrate community conditions. The CSCI and IBI scores for subareas with available benthic macroinvertebrate data are presented in **Table 2-16**. Reaches within subareas with potentially impacted biological condition are identified using an "X". Biological data were included in the SMC and MS4 Permit compliance monitoring datasets. Data ranged from 2005 to 2015.

[9] Relative abundance of taxa within the groups, Trichoptera, Ephemeroptera, and Plecoptera.

Table 2-16: CSCI and IBI Scores Observed Within the SMR WMA During Dry Weather

Subwatershed	Subarea	Reach Name	CSCI	IBI
Upper SMR	Arroyo Seco Creek	Arroyo Seco Creek	**-**	**-**
Middle SMR	Upper Murrieta Creek and Tributaries	Slaughterhouse Canyon	0.87	-
		Cole Canyon	**0.61**	-
	Warm Springs	Warm Springs Creek	0.82	-
		French Valley	**0.49**	-
	Santa Gertrudis Creek	Tucalota Creek	0.79	-
	Murrieta and Long Canyon Creek	Murrieta Creek	**0.55**	**30.26**
	Temecula Creek and Redhawk Channel	Redhawk Channel	**0.641**	-
		Temecula Creek	**0.78**	**27.39**
Lower SMR	Upper Santa Margarita River	Santa Margarita River	0.98	-
	Lower Santa Margarita River	Santa Margarita River	0.87	**22.7**
	Rainbow Creek	Rainbow Creek	1.04	**35.4**
	Fallbrook Creek	Fallbrook Creek	-	**-**
	De Luz Creek	Adobe Creek	0.93	65.5
	Sandia Creek	Sandia Canyon Creek	1.05	-

BOLDED values exceed the identified threshold of CSCI<0.79 or IBI<40 and are indicative of a potentially impacted biological condition.
A dash means no data available.

Four subareas had lowered benthic community scores based on the CSCI. Two subareas in the Lower SMR subwatershed had lowered IBI scores, but the CSCI scores were similar to reference. As the CSCI scores are based on the most recent science and are representative of a broader reference data set, the CSCI scores were used to determine the subareas with lowered scores. The lower scores are indicative of potential aquatic life beneficial use impacts, but need to be considered along with other information (such as algal biomass concentrations and physical habitat scores) to identify potential causes of the impacts.

2.3.2.2.3 Toxicity Data Assessment

Receiving water monitoring for toxicity is conducted as required by the Permit during wet and dry weather conditions. Toxicity results are evaluated using the Test of Significant Toxicity (TST) as outlined in the NPDES Test of Significant Toxicity Implementation Document. Results are considered to be either "pass" or "fail" depending on whether the response observed is significantly different than the control. (USEPA, 2010) In subareas where TST results are not available, the chronic toxic unit calculation (i.e., TUc) is used. When the TUc is above 1.0, the sample is considered to be exceeding the threshold; the larger the toxic unit, the greater the toxicity. The 1.0

TUc threshold was selected based on its use in NPDES permits as a trigger for additional investigation of the causes of toxicity.

Results of chronic toxicity analyses for receiving waters within the SMR WMA are presented in **Table 2-17** and **Table 2-18** for dry and wet weather conditions, respectively, based on data collected from 2005 - 2015.

Table 2-17. Chronic Toxicity Test Results Number of Samples Collected by Category in the SMR WMA During Dry Weather

Subarea	Reach Name	TUc Count			TST Count	
		TUc<1	TUc=1	TUc>1	TST Pass	TST Fail
Upper Murrieta Creek and Tributaries	Slaughterhouse Canyon Cole Canyon	-	-	-	-	-
Warm Springs	Warm Springs Creek French Valley	-	-	-	-	-
Santa Gertrudis Creek	Tucalota Creek	-	-	-	-	-
Murrieta and Long Canyon Creek	Murrieta Creek	-	28	-	-	-
Temecula Creek and Redhawk Channel	Redhawk Channel	-	13	**2**	-	-
	Temecula Creek	-	23	**3**	-	-
Arroyo Seco Creek	Arroyo Seco Creek	-	-	-	-	-
Upper Santa Margarita River	Santa Margarita River	-	13	-	-	-
Lower Santa Margarita River	Santa Margarita River	-	2	-	17	-
Rainbow Creek	Rainbow Creek	-	-	-	-	-
Fallbrook Creek	Fallbrook Creek	-	-	-	-	-
De Luz Creek	Adobe Creek	-	27	**3**	-	-
Sandia Creek	Sandia Canyon Creek	-	11	-	-	-

TUc and TST Test are two different ways of measuring toxicity. When TUc is greater than 1.0 or TST is Fail **(bolded)** the sample is considered to be exceeding thresholds.

Table 2-18. Chronic Toxicity Test Results Number of Samples Collected by Category in the SMR WMA During Wet Weather

Subarea	Reach Name	TUc Count			TST Count	
		TUc<1	TUc=1	TUc>1	TST Pass	TST Fail
Upper Murrieta Creek and Tributaries	Cole Canyon	1	6	**1**	-	-
Warm Springs	Warm Springs Creek French Valley	**-**	**-**	**-**	**-**	**-**
Santa Gertrudis Creek	Tucalota Creek	**-**	**-**	**-**	**-**	**-**
Murrieta and Long Canyon Creek	Murrieta Creek	-	20	**2**	-	-
Temecula Creek and Redhawk Channel	Temecula Creek	-	22	-	-	-
Arroyo Seco Creek	Arroyo Seco Creek	**-**	**-**	**-**	**-**	**-**
Upper Santa Margarita River	Santa Margarita River	**-**	**-**	**-**	**-**	**-**
Lower Santa Margarita River	Santa Margarita River	-	-	-	16	**1**
Rainbow Creek	Rainbow Creek	**-**	**-**	**-**	**-**	**-**
Fallbrook Creek	Fallbrook Creek	**-**	**-**	**-**	**-**	**-**
De Luz Creek	Adobe Creek	-	22	**3**	-	-
Sandia Creek	Sandia Canyon Creek	-	5	-	-	-

TUc and TST Test are two different ways of measuring toxicity. When TUc is greater than 1.0 or TST is Fail **(bolded)** the sample is considered to be exceeding thresholds.
A dash means no data available

The majority of the toxicity samples collected during both dry and wet weather were not toxic. On occasion, toxicity was observed in three subareas during dry weather and four subareas during wet weather. The presence of toxicity indicates potential impacts to aquatic life beneficial uses, but the associated water quality data needs to be evaluated to determine the cause of the toxicity. Toxicity in the SMR WMA has been previously correlated with pyrethroid pesticides. However, neither toxicity nor pyrethroid pesticides are currently persistent in the mass loading station monitoring data. Furthermore, the organophosphate pesticides, chlorpyrifos and diazinon, that have been shown to cause toxicity in other areas of Southern California are no longer regularly detected in the SMR WMA receiving waters.

2.3.2.2.4 Physical Habitat –Erosional Impacts Data Assessment (Provision B.2.a.(7))

The physical habitat conditions of the subareas (**Table 2-20**) were assessed using the California Rapid Assessment Method (CRAM) index. Additionally, information from studies and the public were used to identify potential areas of hydromodification, erosion and sedimentation. CRAM provides an overall summary score for the physical habitat of the monitoring location. (www.cramwetlands.org) CRAM scores range from 25 – 100 and can be divided to reflect physical habitat quality as shown in **Table 2-19**. The CRAM scores account for channel substrate and evidence of erosion within the assessment methodology.

Four attributes of riverine stream evaluation:

1. buffer and landscape context (i.e., stream corridor continuity, stream buffers)
2. hydrology (i.e., water source, channel stability, hydrologic connectivity),
3. physical structure (i.e., structural patch richness, topographic complexity), and
4. biotic structure (i.e., plant community composition, horizontal interspersion, and vertical biotic structure).

Table 2-19. Habitat Quality Indicated by CRAM Score

Habitat Quality	CRAM Score
High	> 75
Moderate	50 - 75
Low	< 50

In the Middle SMR Subwatershed, the CRAM scores were obtained from the SMC dataset and the hydromodification project monitoring report (from 2005 to 2015). In the Lower SMR Subwatershed, the CRAM scores were obtained from the SMC and SWAMP datasets (from 2008 to 2015). Results of the physical habitat assessment are presented in **Table 2-20**, respectively. For the purposes of the assessment, CRAM scores below 50 alone (i.e., a low habitat quality) and CRAM scores between 50 and 75 (i.e., a moderate habitat quality), combined with evidence of hydromodification, were considered indicative of potential impacts to aquatic life.

Table 2-20. CRAM Scores Observed Within the SMR WMA During Dry Weather

Subwatershed	Subarea	Reach Name	CRAM Score	Evidence of Hydromodification
Upper SMR	Arroyo Seco Creek	Arroyo Seco Creek	-	-
Lower SMR	Upper Murrieta Creek and Tributaries	Slaughterhouse Canyon	67	-
	Warm Springs	Warm Springs Creek	**63**	✓
		French Valley	70	-
	Santa Gertrudis Creek	Tucalota Creek	78	-
	Murrieta and Long Canyon Creek [1]	Long Canyon	**-**	✓
		Murrieta Creek	74	-
	Temecula Creek and Redhawk Channel	Temecula Creek	73	-
	Upper Santa Margarita River	Santa Margarita River	84	-
	Lower Santa Margarita River	Santa Margarita River I	84	-
	Rainbow Creek	Rainbow Creek	73.4	-
	Fallbrook Creek	Fallbrook Creek	-	-
	De Luz Creek	Adobe Creek	74	-
	Sandia Creek	Sandia Canyon Creek	86	-
		Sandia Canyon Creek	80	-

CRAM scores below 50 are automatically considered indicative of potential impacts to aquatic life. A CRAM score between 50 and 75 with other evidence of hydromodification was also considered to be potentially impacting (**bolded**).

A dash means no data available

1. CRAM index scores from Murrieta Creek and evidence of hydromodification on Long Canyon Creek. The WMAA analysis found that the hydromodification exemption could be applied to Murrieta Creek, indicating hydromodification is not a concern in that reach of the subarea.

In addition to the CRAM index scores, stream conditions and potential areas of erosion and observed hydromodification were considered in the assessment. The Consultation Committee provided comments with areas recommended for investigation for potential erosion/hydromodification concerns in the Middle SMR Subwatershed. These areas, along with the characteristics of the channels are shown in **Figure 2-7**. Similar information is not available for the Lower SMR Subwatershed and no areas for investigation were identified in the Lower SMR Subwatershed.

Evidence of erosion/hydromodification was assessed by reviewing available reports and information provided during the data request. Two key documents were identified that discussed physical habitat conditions, potential hydromodification, and erosion/sedimentation impacts. The Hydromodification Monitoring Project documented hydromodification surveys at two streams within the Cities of Temecula and Murrieta in the Middle SMR Subwatershed; however, this report contained no hydromodification surveys for sites in the Upper or Lower SMR Subwatersheds. Parameters observed and measured in this report included channel dimensions, hydrological and geomorphic conditions, presence and condition of vegetation and habitat, location of discharge points, habitat integrity, dimensions of existing channel bed or bank erosion and known or suspected causes of existing downstream erosion or habitat impact. Two areas were

identified as having evidence of erosion/hydromodification based on this report, Long Canyon Creek in the Murrieta Creek and Long Canyon subarea, and Warm Springs Creek in the Warm Springs subarea.

The Bioassessment of Perennial Streams in Southern California: A Report on the First Five Years of the Stormwater Monitoring Coalition's Regional Stream Survey was also reviewed for evidence of erosion/hydromodification in the SMR WMA. This report was conducted at a regional level, evaluating watersheds at a hydrologic scale larger than the SMR WMA that ranged from Ventura to San Diego. This report utilized data from the SMC dataset and contained summary statistics for physical habitat variables relating to biomass, instream habitat, riparian characteristics and stream substrates. No mention of erosion processes was included and, therefore, no additional areas of concern were identified based on this report.

In addition to the reviewed reports and data, the analysis conducted to evaluate the potential for a hydromodification exemption for Murrieta Creek, Temecula Creek, and the Upper and Lower Santa Margarita River as part of the Watershed Management Area Analysis (**Appendix 4B**) was also considered. The analysis determined that the hydromodification exemption could be applied to Murrieta Creek and the Upper and Lower Santa Margarita River reaches. As a result, evidence of hydromodification/erosion was not identified for these areas. The potential for erosion was identified in the lower portion of Temecula Creek in the analysis.

The results of the assessment show that the CRAM scores were generally good throughout the SMR WMA, although there were a few areas in the Middle SMR Subwatershed where there is evidence of erosion/hydromodification and some other subareas of potential concern identified by the Consultation Committee and in the WMAA analysis (**Figure 2-7**).

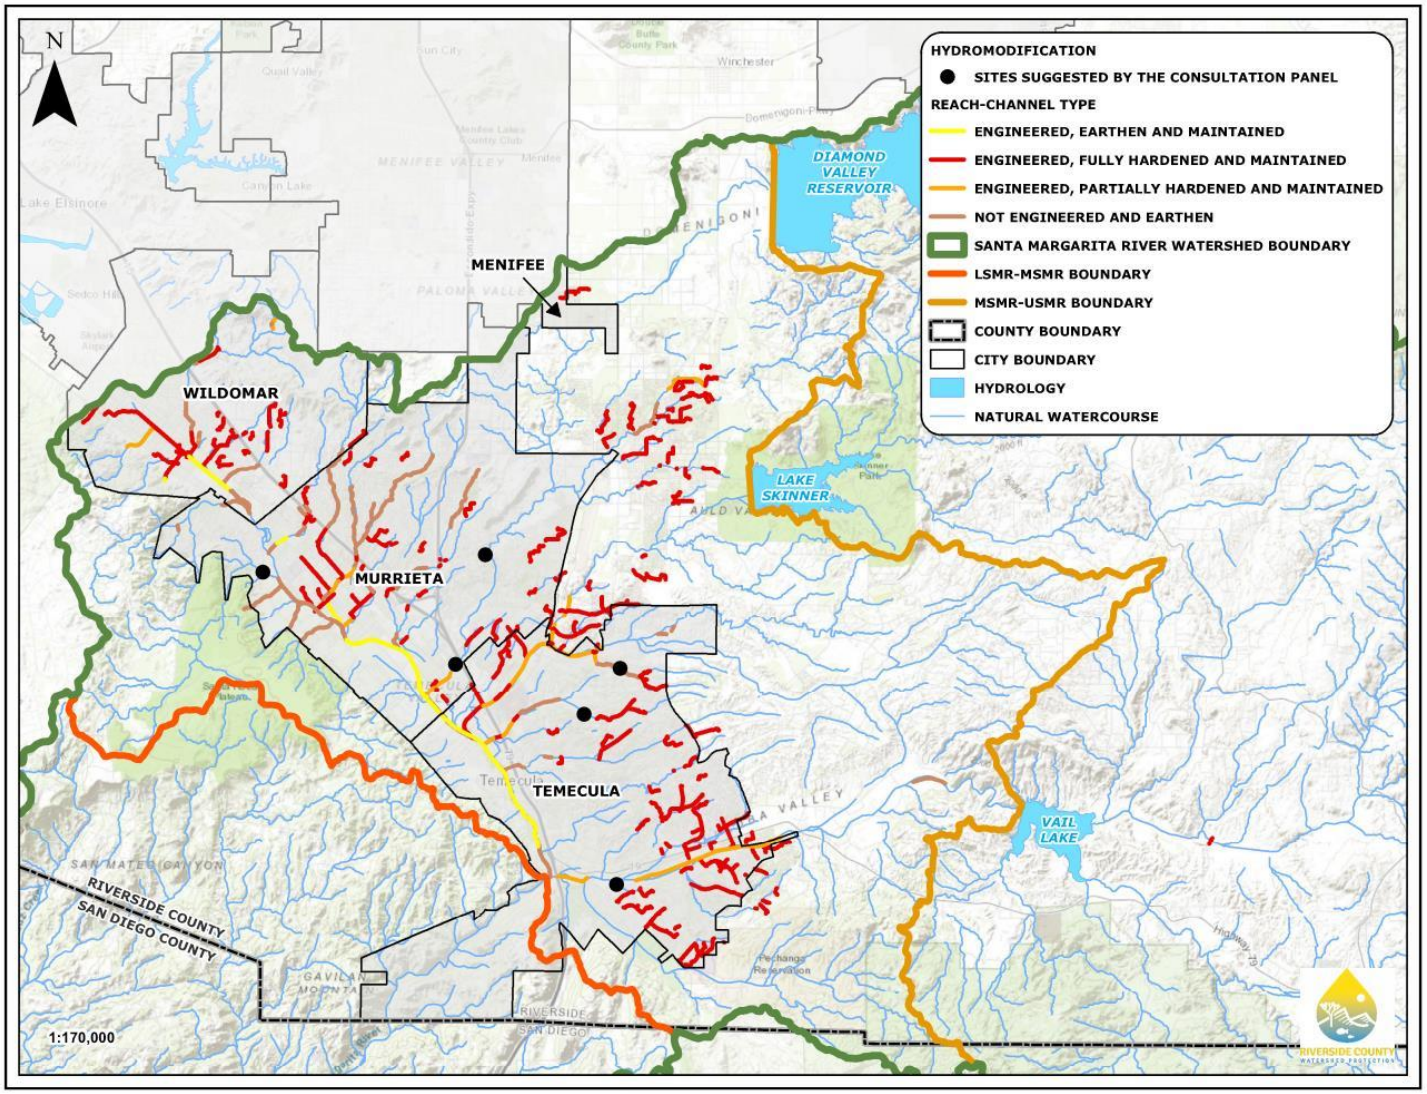

Figure 2-7. Middle SMR Subwatershed Channel Characteristics and Areas Identified by Consultation Committee for Investigation

2.3.2.2.5 Trash Data Assessment

The Statewide Trash Amendments identify specific priority land uses for trash for which the amendments are applicable, based on the potential to impact aquatic life and recreational beneficial uses in receiving waters. While the Middle SMR Subwatershed and Fallbrook Creek are the only areas that have been identified with priority land uses, additional data available from special studies were assessed to determine if any additional subareas should be added. The Upper SMR Subwatershed has not been evaluated for potential priority land use areas pursuant to the trash amendments. Results from trash assessments conducted within the Middle SMR Subwatershed and Lower SMR Subwatershed are summarized in **Table 2-21** and **Table 2-22**, respectively.

Table 2-21. Trash Conditions Within the Upper and Middle SMR Subwatershed Subareas

Subwatershed	Subarea	Dry Weather		Wet Weather	
		Rating	Score	Rating	Score
Upper SMR	Arroyo Seco Creek	N/A	N/A	N/A	N/A
Middle SMR	Upper Murrieta Tributaries	Optimal	111	Optimal	119
	Warm Springs	Suboptimal	85	Suboptimal	88
	Murrieta Creek and Long Canyon Creek	Suboptimal	86	Suboptimal	90
	Santa Gertrudis Creek	Optimal	107	Optimal	103
	Temecula Creek and Redhawk Channel	Suboptimal	80	Suboptimal	81

[1] Results from Trash and Litter Investigation Special Study.
[2] Assessment conducted in accordance with Rapid Trash Assessment (RTA) protocols to develop scores. Scores were assigned to the categories of optimal and suboptimal in accordance with the RTA category descriptions.
[3] N/A – no data for assessment

Table 2-22. Dry Weather MS4 Outfall Field Screening Trash Assessments Within the Lower SMR Subwatershed (Source: 2015-2016 TMAR)

Copermittee	Hydrologic Subarea	Trash Present (# of sites)			
		None	Low (<50 pieces)	Medium (50 to 400 pieces)	High (>400 pieces)
County of San Diego	902.13	1	5	2	2
	902.23	1	8	1	0
	Total	2	13	3	2

Based on the data presented above showing minimal trash in the measured areas, no additional subareas were identified for consideration of impacts due to trash.

2.3.3 Identification of Potential PWQCs in Receiving Waters Based on Step 1 and Step 2 Data Assessments

Potential PWQCs were identified by integrating the Step 1 assessments with the Step 2 assessments of locations of known beneficial use locations and an evaluation of physical and biological indicators for each beneficial use category. The potential PWQCs and associated chemical, physical, and biological indicators for each beneficial use category are summarized in **Table 2-23**.

Table 2-23. Potential PWQCs by Beneficial Use Category

Potential PWQCs	Physical, Chemical, and Biological Indicators	Beneficial Use Category
Eutrophication	Algal biomass Benthic community indices Dissolved Oxygen	
Nutrient Loading to TMDL Waterbodies	Total Nitrogen Total Phosphorus	
Toxicity		
	Ammonia Pesticides [1] Metals [2] Toxicity	Aquatic Life
Physical Habitat		
	Sediment Physical habitat scores (CRAM) Evidence of erosion and hydromodification	
Nuisance	Trash	Aquatic Life and Recreation
Indicator Bacteria	Fecal Coliform *E. coli*	Recreation
Constituents of concern for drinking water supplies	Nitrate Title 22 Constituents[3]	Water Supply
Constituents of concern for agricultural supply	Total Dissolved Solids Chloride Boron	Agricultural Supply
Constituents of concern for industrial supply	pH Total Dissolved Solids	Industry

This section summarizes the results of the analysis from the previous sections of the indicators shown in **Table 2-23** to determine the subareas with each potential PWQC based on the receiving water analysis. In Step 3, the potential contributions from MS4 discharges will be compared to the potential PWQCs identified from the receiving water analysis to determine the PWQCs for the WQIP. Each column in the following set of tables represents a type of analysis that was conducted by geographic reach. By reviewing the data in this way, this section 2B will result in a complete list of Potential PWQCs (**Table 2-30**).

2.3.3.1 Aquatic Life-Eutrophication PWQC

Eutrophication is caused by excessive growth of algal biomass. Elevated biomass levels cause changes in water column and sediment chemistry that can cause fish kills and impact benthic communities. As shown in **Figure 2-8**, eutrophication can be assessed by measuring macroalgae and phytoplankton and the associated changes in DO and pH in the water column. Additionally, eutrophication symptoms can result from excess TN and TP loading. While TN and TP may not cause eutrophication in all areas of the watershed, even when above assessment thresholds, the elevated nutrient concentrations can contribute to downstream eutrophication impacts. Therefore, all of these indicators were evaluated in the assessment of the potential PWQC of eutrophication.

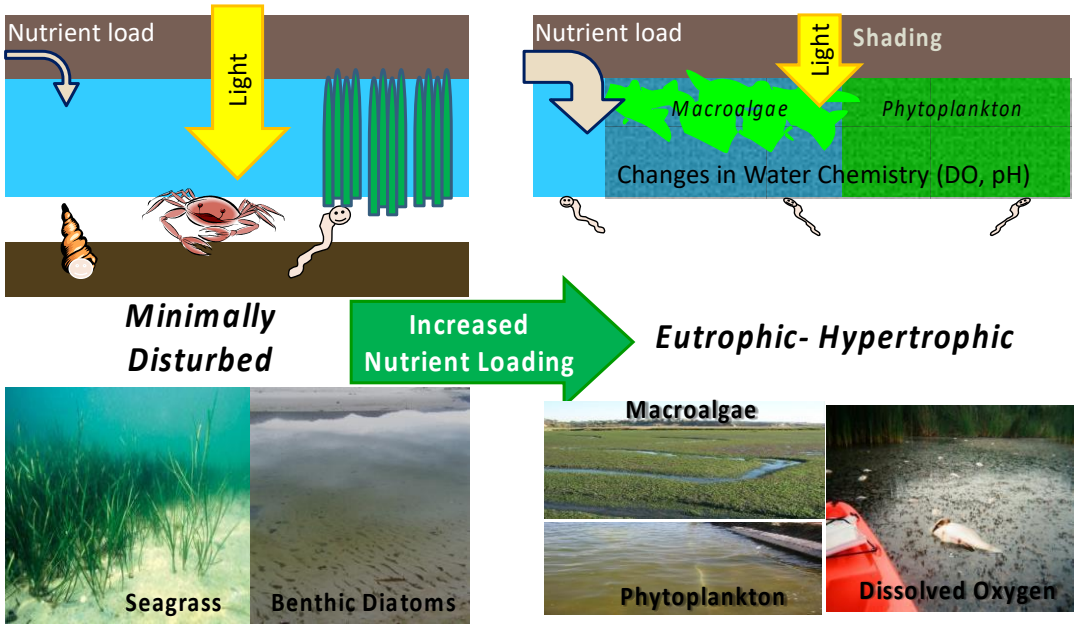

Figure 2-8. Conceptual Model of Eutrophication in Mediterranean Estuaries (from Model Application Report)

While all of the metrics discussed above are indicative of eutrophication, elevated levels of nutrients or other indicators may or may not have an impact on aquatic life beneficial uses, due to physical factors or other waterbody conditions (Sutula, et al., 2016). Benthic macroinvertebrate community condition can be used to assess whether the elevated algal biomass is impacting aquatic life beneficial uses. As a result, the benthic community condition data were also used in the eutrophication assessment. The results of the assessment are summarized in **Table 2-24**.

Table 2-24. Summary of Eutrophication PWQC Assessment Results

Subwatershed	Subarea	303(d) Listings for Associated Chemical Indicators	TMDL	Nitrogen Above Assessment Threshold	Phosphorus Above Assessment Threshold	Algal Biomass Above Threshold	Benthic Below Threshold	Dissolved Oxygen
Upper SMR	Arroyo Seco Creek	No	No [1]	No	No	No	N/A	**D**
Middle SMR	Upper Murrieta Creek and Tributaries	No	No [1]	No	**W**	No	No	No
	Warm Springs	**Yes**	No [1]	**W**	**W**	**D**	**D**	No
	Murrieta and Long Canyon Creek	**Yes**	No [1]	**W**	**D, W**	No	**D**	**D,W**
	Santa Gertrudis Creek	**Yes**	No [1]	**W**	**D, W**	No	No	No
	Temecula Creek and Redhawk Channel	**Yes**	No [1]	**D, W**	**D, W**	**D**	**D**	**D**
Lower SMR	Upper Santa Margarita River	**Yes**	No [1]	No	**W**	No	No	**D**
	Lower Santa Margarita River	**Yes**	No [1]	**D**	**W**	No	No	**D**
	Rainbow Creek	**Yes**	**Yes [2]**	**D, W**	**D, W**	N/A	No	**D, W**
	Fallbrook Creek	No	No	**D**	**D, W**	N/A	N/A	**D**
	De Luz Creek	**Yes**	No [1]	**D**	**W**	No	N/A	**D**
	Sandia Creek	No	No [1]	**D**	**D, W**	No	No	No
	Santa Margarita River Estuary	**Yes**	No [1]	**D, W**	**D, W**	N/A	N/A	No

N/A: no data for assessment; Threshold exceedance: D for dry weather; W for wet weather.

1. TMDL Alternative (under development) for the SMR Estuary identifies dry weather nutrient loading from the subarea to be potentially contributing to eutrophication concerns in the SMR Estuary.
2. Effective TMDL with dry and wet weather allocations for MS4s.

Results of the analysis show that many subareas are above the assessment threshold for nitrogen and phosphorus and have the potential to contribute nutrient loading to eutrophic conditions in the SMR Estuary. All subareas that have elevated nitrogen or phosphorus concentrations and are considered as part of a TMDL or TMDL Alternative have a potential PWQC of nutrient loading to a TMDL waterbody. Additionally, Warm Springs and Temecula Creek and Redhawk Channel have elevated algal biomass levels and lowered benthic community condition results, indicating the potential for localized eutrophication concerns and are, therefore, assigned a potential PWQC of eutrophication along with SMR Estuary which is listed for eutrophication. Murrieta and Long Canyon Creek subarea had benthic community measurements below thresholds, but did not have associated elevated algal biomass above thresholds so were not assigned a potential eutrophication PWQC. Santa Gertrudis Creek subarea benthic community scores were around the threshold, but the algal biomass levels were not above thresholds and, therefore, the subarea was not assigned a potential eutrophication PWQC.

2.3.3.2 Aquatic Life-Toxicity PWQC

Toxicity can be assessed in the water column and in sediment, each of which can affect the aquatic life. Toxicity is directly measured through toxicity testing, but the potential for toxicity can also be assessed through the examination of constituents that have the potential to cause toxicity to water quality objectives. The assessment of toxicity considered both the results of toxicity tests and evaluation of constituents most likely to cause toxicity. Toxicity in the Santa Margarita River WMA has been previously correlated with pyrethroid pesticides. Organophosphate pesticides, ammonia and metals are other constituents that have the potential to cause or contribute to receiving water toxicity.

The assessment of chemical, physical and biological indicators associated with toxicity are summarized in **Table 2-25**. The assessment included the Step 2 evaluation of toxicity samples and results from the exceedance analyses of pesticides, metals, and ammonia conducted in Step 1B.

Table 2-25. Summary of Toxicity PWQC Assessment Results

Subwatershed	Subarea	303(d) Listings	TMDL	Toxicity Above Assessment Threshold	Pesticides Above Assessment Threshold	Metals Above Assessment Threshold	Ammonia Above Assessment Threshold

	Lower Santa Margarita River	No	No	No	N/A	No	No
	Rainbow Creek	No	No	N/A	N/A	No	No
	Fallbrook Creek	No	No	No	N/A	No	No
	De Luz Creek	No	No	N/A	N/A	No	No
	Sandia Creek	No	No	No	N/A	**D[4]**	No
	Santa Margarita River Estuary	No	No	N/A	N/A	No	**D**

N/A: no data for assessment; Threshold exceedance: D for dry weather; W for wet weather.

1. Simazine is the only pesticide with exceedances in this subarea.
2. Copper is the only metal with exceedances in this subarea.
3. Chlorpyrifos is the only pesticide with exceedances in this subarea.
4. Selenium is the only metal with exceedance in this subarea.
5. Listings for chlorpyrifos and copper were not confirmed during the Step 1B exceedance analysis.
6. Listing for chlorpyrifos was not confirmed during the Step 1B exceedance analysis.

7. Listing for toxicity was not confirmed by the Step 2 toxicity data assessment.

Results of the analysis show that observed toxicity is limited to a few subareas and the organophosphate pesticides, that may have historically contributed to toxicity, are no longer exceeding in receiving waters.

Constituents potentially contributing to toxicity, including diazinon and copper, exceeded thresholds in a few subareas. Additionally, although 303(d) listings for constituents potentially contributing to toxicity (e.g. copper and chlorpyrifos) exist in most subwatersheds, most of these listings were not confirmed in the Step 1B exceedance analysis and the pesticide trends indicate improving conditions. The Murrieta and Long Canyon Creek and Temecula Creek and Redhawk Channel subareas were assigned potential PWQCs of observed toxicity due to observed toxicity in the subareas and continuing exceedances of WQOs for constituents that could potentially contribute to toxicity. Warm Springs, Sandia Creek and SMR Estuary had some constituents that were above objectives, but no associated toxicity so were not assigned this potential PWQCs.

2.3.3.3 Aquatic Life-Physical Habitat PWQC

Physical habitat is important for protection of aquatic life. Erosion of stream channels, increased sediment deposition, and modified channels can alter conditions necessary to support spawning and macroinvertebrate communities. Several factors can be used to evaluate physical habitat including channel substrate, evidence of erosion, and the creek rapid assessment methods.

Table 2-26. Summary of Physical Habitat PWQC Assessment Results

Subwatershed	Subarea	303(d) Listing	TMDL	CRAM Index Score below threshold	Benthic Below Threshold	Evidence of Hydromodification[1]
Upper SMR	Arroyo Seco Creek	No	No	N/A	N/A	No
Middle SMR	Upper Murrieta Creek and Tributaries	No	No	No[2]	No	(4)
	Warm Springs	No	No	No[2]	**D**	**Yes**
	Murrieta and Long Canyon Creek[3]	No	No	No[2]	**D**	**Yes**
	Santa Gertrudis Creek	No	No	No	No	No
	Temecula Creek and Redhawk Channel	No	No	No[2]	**D**	(4)
Lower SMR	Upper Santa Margarita River	No	No	No	No	N/A
	Lower Santa Margarita River	No	No	No	No	N/A
	Rainbow Creek	No	No	No[2]	No	N/A
	Fallbrook Creek	No	No	N/A	N/A	N/A
	De Luz Creek	No	No	No[2]	N/A	N/A
	Sandia Creek	No	No	No	No	N/A
	Santa Margarita River Estuary	No	No	N/A	N/A	N/A

N/A: no data for assessment; Threshold exceedance: D for dry weather; W for wet weather.

1. As reported in the Hydromodification Monitoring Project Report.
2. As described above, the CRAM threshold is <50. However, for scores between 50 and 75, physical habitat impacts were considered a PWQC if there was also evidence of hydromodification. These reaches had CRAM scores between 50 and 75.
3. CRAM index scores from Murrieta Creek and evidence of hydromodification on Long Canyon Creek. The WMAA analysis found that the hydromodification exemption could be applied to Murrieta Creek, indicating hydromodification is not a concern in that reach of the subarea.
4. Areas are under investigation for erosion/sediment impacts at the sites identified by the Consultation Committee and in Temecula Creek based on the results of the WMAA.

Warm Springs and Murrieta and Long Canyon Creek were identified as subareas having potential PWQCs for lowered physical habitat scores (CRAM) or evidence of hydromodification/erosional impacts. Subareas with sites under investigation based on input from the Consultation Committee and the WMAA may be included as a PWQC in the future if the investigations confirm evidence of hydromodification/erosional impacts. The Temecula Creek and Redhawk Channel subarea was not assigned this PWQC at this time because the elevated algal biomass values are likely contributing to the lowered benthic community scores, but may be added after further investigation of potential erosion impacts in the reach as follow up to the WMAA and Consultation Committee input.

2.3.3.4 Recreation-Indicator Bacteria PWQC

Recreation beneficial uses are impacted by the presence of pathogens that have the potential to cause illness. Indicator bacteria, such as *E. coli*, fecal coliform, and *Enterococcus* are used to assess the potential risk of illness. No other physical or biological indicators were identified as

indicators for the recreation beneficial use category. The assessment for recreation utilizes indicator bacteria results from the Step 1 analysis as summarized in **Table 2-27**.

Table 2-27. Summary of Recreational Beneficial Use Impact Assessment

Subwatershed	Subarea	303(d) Listings	TMDL	Fecal Coliform Above Threshold	*E. coli* Above Threshold	Location of Known Recreation	Flow Condition Supportive of Recreation
Upper SMR	Arroyo Seco Creek	No	No	No	No	No	No
Middle SMR	Upper Murrieta Creek and Tributaries	No	No	**W**	**W**	No	No
	Warm Springs	**Yes**	No	**W**	**W**	No	**Yes**
	Murrieta and Long Canyon Creek	**Yes**	No	**W**	**W**	**Yes**	**Yes**

	Santa Margarita River Estuary	No	No	No	No	**Yes**	**Yes**

Threshold exceedance: D for dry weather; W for wet weather.

All subareas with fecal coliform or E. coli values above thresholds were assigned to this potential PWQC.

2.3.3.5 Municipal Supply-Constituents of Potential Concern for Municipal Supply PWQC

The municipal supply beneficial use can be impacted by elevated concentrations of constituents that have the potential to impact the health of people drinking the water. The constituents that could impact the municipal supply beneficial use are those that have identified objectives for the protection of human health as outlined in Title 22. A list of these constituents is included in **Appendix 2**. No physical or biological indicators were identified for consideration for the municipal supply beneficial use category. The assessment of chemical indicators associated with municipal supply are summarized in **Table 2-28** based on the analysis conducted in Step 1.

Table 2-28. Summary of Municipal Supply Beneficial Use Impact Assessment

Subwatershed	Subarea	303(d) Listings	TMDL	Nitrate Above Threshold	Title 22 Above Threshold	Location of Known Municipal Supply Diversion
Upper SMR	Arroyo Seco Creek	No	No	No	No	No
Middle SMR	Upper Murrieta Creek and Tributaries	No	No	No	W[1,2]	No
	Warm Springs	Yes[1,2]	No	No	W[1,2,4,5]	No
	Murrieta and Long Canyon Creek	Yes[1,2]	No	No	D,W[1,2,4,5]	No
	Santa Gertrudis Creek	Yes[1,2]	No	No	D,W[1,2,4,5]	No
	Temecula Creek and Redhawk Channel	Yes[1,2,4]	No	No	D,W[1,2,3,4,5]	No
Lower SMR	Upper Santa Margarita River	No	No	No	D[1]	No
	Lower Santa Margarita River	No	No	D,W	D,W[1,2,3,4]	Yes
	Rainbow Creek	Yes[1,3,4]	No	D,W	D,W[2,3,4]	No

	Sandia Creek	Yes[1,3,4]	No	No	D,W[1,3,4]	No
	Santa Margarita River Estuary	(6)	(6)	(6)	(6)	(6)

N/A: no data for assessment; Threshold exceedance: D for dry weather; W for wet weather.

1. Iron
2. Manganese
3. Sulfate
4. TDS
5. Color
6. Municipal drinking water beneficial use does not apply to the Santa Margarita River Estuary so the analysis was not conducted for this subarea.

All subareas with nitrate or Title 22 constituents values above thresholds were assigned to this potential PWQC.

Agricultural and Industrial Supply

Potential impacts to agricultural and industrial supply were evaluated through assessments of the potential PWQCs: constituents of potential concern for agricultural and industrial supply.

Agricultural and industrial supply beneficial uses are potentially impacted by constituents, that at elevated concentrations, can impact the viability of agriculture or impact industrial processes. TDS, chloride and boron are constituents that could adversely impact agriculture and TDS and pH could potentially impact industrial uses. No physical or biological indicators were identified for consideration for these beneficial use categories. The assessment of chemical indicators associated with agricultural and industrial supply are summarized in **Table 2-29** based on the analysis conducted in Step 1.

Table 2-29. Summary of Agricultural and Industrial Supply Beneficial Use Impact Assessment

Subwatershed	Subarea	303(d) Listings	TMDL	TDS Above Threshold	Chloride Above Threshold	Boron Above Threshold	pH Above Threshold	AGR: Location of Known Agricultural Supply Diversion?	IND: Location of Known Industrial Diversion?
Upper SMR	Arroyo Seco Creek	No	No	No	No	N/A	D	No	No
Middle SMR	Upper Murrieta Creek and Tributaries	No	No	No	N/A	N/A	No	No	No
	Warm Springs	No	No	W	No	N/A	No	No	No

Note: Potential PWQCs are indicated by an "X" in the table.

1. Identified as potential PWQC based on TMDL Alternative studies.
2. Evidence of hydromodification on Long Canyon Creek only. The WMAA analysis found that the hydromodification exemption could be applied to Murrieta Creek, indicating hydromodification is not a concern in that reach of the subarea.

2.4 STEP 3. ASSESSMENT OF POTENTIAL IMPACTS FROM MS4 DISCHARGES

The assessment of receiving water conditions in Steps 1 and 2 identified potential PWQCs of concern in receiving waters within the SMR WMA. Step 3 assesses if discharges from MS4s could cause or contribute to the potential PWQCs. The assessment was conducted by identifying the locations where MS4 discharges occur. Then, representative chemical monitoring data and persistent flow data were reviewed to determine which constituents the MS4 discharges may be contributing to receiving waters to create the list of PWQCs.

2.4.1 Locations of MS4 Discharges (Provision B.2.b.(3))

As a first step, the locations of each Copermittee's MS4 outfalls, as defined in the Regional Permit, that discharge to receiving waters were identified to assess where MS4 discharges were most likely to contribute to receiving water conditions identified in Step 2. For most of the subareas, MS4 contributions are a possibility where there are MS4 outfalls and jurisdictional area within or upstream of the subarea (see **Figure 3-4**).

2.4.2 Identification of Potential PWQCs Which MS4 Discharges May be Contributing (Provisions B.2.b.(1), B.2.b.(2), B.2.b.(4) and B.2.b.(5))

Monitoring data from Copermittee's MS4 outfalls was compared to established thresholds to determine whether or not MS4s s are contributing pollutants. All relevant and appropriate data for both stormwater and non-stormwater discharges were considered. MS4 outfall monitoring locations are shown in **Figure 2-10**. The outfall monitoring stations shown in Figure 2-10 represent the best available information on the locations ofMS4 outfalls that discharge pollutants and are considered representative of all MS4 outfalls that discharge to receiving waters. Locations of outfalls with persistent non-stormwater flow are shown in **Figure 2-11**. All of the Upper SMR Subwatershed, and the Pechanga Creek and Sandia Creek subareas do not have storm drain outfall monitoring data and are primarily comprised of open space and federal lands. Due to the lack of data and the minimal amount of urban land use in these subareas, MS4 discharges were not identified as contributing to potential PWQCs in these subareas. As a result, no PWQCs are assigned for these subareas, but modifications will be considered during the adaptive management process if data are collected that identify MS4 contributions to potential PWQCs in these areas.

As discussed further in **Section 2.5.2**, the assessment of potential impacts of the MS4 discharges on the receiving waters is based on limited MS4 outfall data. While the available data generally support characterization of the discharges from the MS4s, the limited spatial extent of data from the MS4 outfalls means the assessment of the potential impacts from storm drain outfalls for a whole subarea is based on data from a single outfall and the results may not be fully representative of conditions across the whole subarea. The assessment of MS4 discharge impacts on receiving waters will improve over time as this data gap is addressed by future outfall monitoring and non-stormwater field screening.

Although limitations on the amount of MS4 outfall discharge data exist, the available data were considered representative for the purposes of the analysis. At least one MS4 outfall monitoring location was available in each subarea within the Middle and Lower SMR Subwatersheds, with the exception of the Pechanga Creek, Sandia Creek, and SMR Estuary subareas, which have a minimal amount of urban land use and are primarily comprised of open space and federal lands. Therefore,

the analysis assumes that all MS4 outfalls within a subarea have the potential to discharge any pollutants that are observed in the representative outfall(s) for that subarea.

The procedure for assessing the contribution of MS4 discharges to the potential PWQCs identified in Step 2 is shown in **Figure 2-9**. The potential for non-storm water discharges to cause or contribute to impacts on beneficial uses was assessed in the same method as storm water discharges and all outfalls identified as persistent in Figure 2-11 are assumed to potentially contribute pollutants to receiving waters under dry weather conditions. Based on the Step 3 assessment, the subareas with identified MS4 discharges potentially contributing to PWQCs are shown in **Figure 2-9. Table 2-31** summarizes the results of the MS4 discharge assessment for each of the potential PWQCs identified in Step 2. If the indicator of the impact was not available for the MS4 outfall data, the potential PWQC was noted as "N/A" in the table. If the MS4 outfall data demonstrated exceedances, the potential PWQC is identified with an "X" in the table. If the MS4 outfall data did not demonstrate exceedances of an indicator, a footnote is referenced in the table to explain the assessment.

Impacts are summarized by wet and dry weather conditions and organized according to beneficial use category. Further investigation of the contribution of discharges from MS4 outfalls to the PWQCs will be conducted as part of the Monitoring and Assessment Program and may result in refinement of the PWQCs or the geographic extent of these conditions.

1. MS4 outfall data do not exceed in at least two samples and more than 10% of the time for this indicator.
2. Simazine is the only pesticide observed as having exceedances in receiving waters. No outfall data for simazine are available. Other pesticides, particularly bifenthrin, that may contribute to toxicity have been observed above thresholds in these outfalls, but receiving water data for other pesticides did not exceed thresholds.
3. No MS4 outfalls are located in the subarea to assess potential impacts. No MS4 outfalls are present. Upstream MS4 discharges may contribute to any PWQC identified in the receiving waters in the subarea.
4. No MS4 outfall data for this subarea so no PWQCs are identified.
5. MS4s are presumptively assumed to be contributing trash from priority land uses under the Statewide Trash Amendments.

2.5 STEP 4A PRIORITY WATER QUALITY CONDITIONS

2.5.1 Priority Water Quality Conditions (Provisions B.2.c.(1)(a-d))

PWQCs were determined based on the analysis conducted in Steps 1-3. The potential PWQCs were identified in **Table 2-30** and the potential impact of the discharges from MS4 outfalls on those potential PWQCs is shown in **Table 2-31**. As shown in **Table 2-31**, not all physical, chemical, and biological indicators can be assessed with MS4 outfall data and outfall data are not available in some areas. As a result, the PWQCs were determined using the following procedure:

1. If the MS4 contributed a chemical indicator that was associated with the PWQC to a subarea, the potential PWQC was identified as a PWQC for all indicators associated with the PWQC. For example, if a MS4 contributed nitrogen or phosphorus to a subarea and the receiving water exceeded algal biomass thresholds, eutrophication was assigned as a PWQC even though algal biomass cannot be measured in the MS4 outfalls.
2. If no MS4 outfall data were available for a subarea that receives MS4 discharges (e.g. Upper Santa Margarita River), the potential PWQC was considered a PWQC if the upstream MS4 outfall data exceeded for the indicator.

Based on this procedure, the identified PWQCs are summarized in **Table 2-32** along with the beneficial use category, geographic and temporal extent, and the responsible agency(ies) for each PWQC. The PWQCs identified for each subarea are shown in **Figure 2-13.** The industrial supply beneficial use category did not have any identified PWQCs because no industrial diversions were identified and the related exceedances of TDS are addressed by the agricultural BU category PWQCs.

Table 2-32. Priority Water Quality Conditions

BU Category	Priority Water Quality Condition	Temporal Extent	Geographic Extent	Responsible Agency(ies)
Aquatic Life Use: Eutrophication	Eutrophication (elevated algal biomass)	Dry	SMR Estuary[1], Warm Springs, Redhawk Channel	All Agencies
	Nutrient loading to waterbodies with an adopted TMDL or listed as impaired	Dry	All Middle and Lower SMR subareas, except Fallbrook Creek and Sandia Creek[1]	All Agencies
		Wet	Rainbow Creek	San Diego County
Aquatic Life Use: Toxicity	Observed toxicity	Dry	Temecula Creek and Redhawk Channel	RCFCWCD Riverside County Temecula
		Wet	Murrieta Creek and Long Canyon	Menifee Murrieta Temecula RCFCWCD Riverside County Wildomar

BU Category	Priority Water Quality Condition	Temporal Extent	Geographic Extent	Responsible Agency(ies)
Aquatic Life Use: Physical Habitat	Lowered physical habitat scores (CRAM) or evidence of hydromodification/ erosional impacts	Wet	Warm Springs, Murrieta Creek and Long Canyon	Menifee Murrieta RCFCWCD Riverside County Temecula Wildomar
Aquatic Life Use / Recreation: Nuisance Conditions	Trash	Dry	All Middle SMR subareas, Fallbrook Creek	All Agencies
		Wet	All Middle SMR subareas, Fallbrook Creek	All Agencies
Recreation	Indicator Bacteria Concentrations	Dry	Temecula Creek and Redhawk Channel and De Luz Creek	RCFCWCD Riverside County San Diego County Temecula
		Wet	Upper Murrieta Creek, Warm Springs, Murrieta Creek and Long Canyon, Santa Gertrudis Creek, Temecula Creek and Redhawk Channel	Menifee Murrieta Temecula RCFCWCD Riverside County Wildomar
Municipal Supply	Constituents of potential concern for municipal supplies (Iron, Manganese)	Dry	Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Rainbow Creek, Lower Santa Margarita River, Fallbrook Creek, De Luz Creek	Murrieta Temecula RCFCWCD Riverside County San Diego County
		Wet	All Middle SMR subareas, Rainbow Creek	All Agencies
Agricultural Supply	Constituents of potential concern for agricultural supply (TDS)	Dry	Santa Gertrudis Creek, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Rainbow Creek, Lower Santa Margarita River, Fallbrook Creek	Murrieta Temecula RCFCWCD Riverside County San Diego County
		Wet	Rainbow Creek	San Diego County

1. Discharges from MS4 outfalls within these subareas may reach the SMR Estuary during dry weather and contribute to the Eutrophication PWQC in the Santa Margarita River Estuary: Upper Murrieta Creek and Tributaries, Warm Springs, Santa Gertrudis, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Lower Santa Margarita River, Rainbow Creek and De Luz Creek.

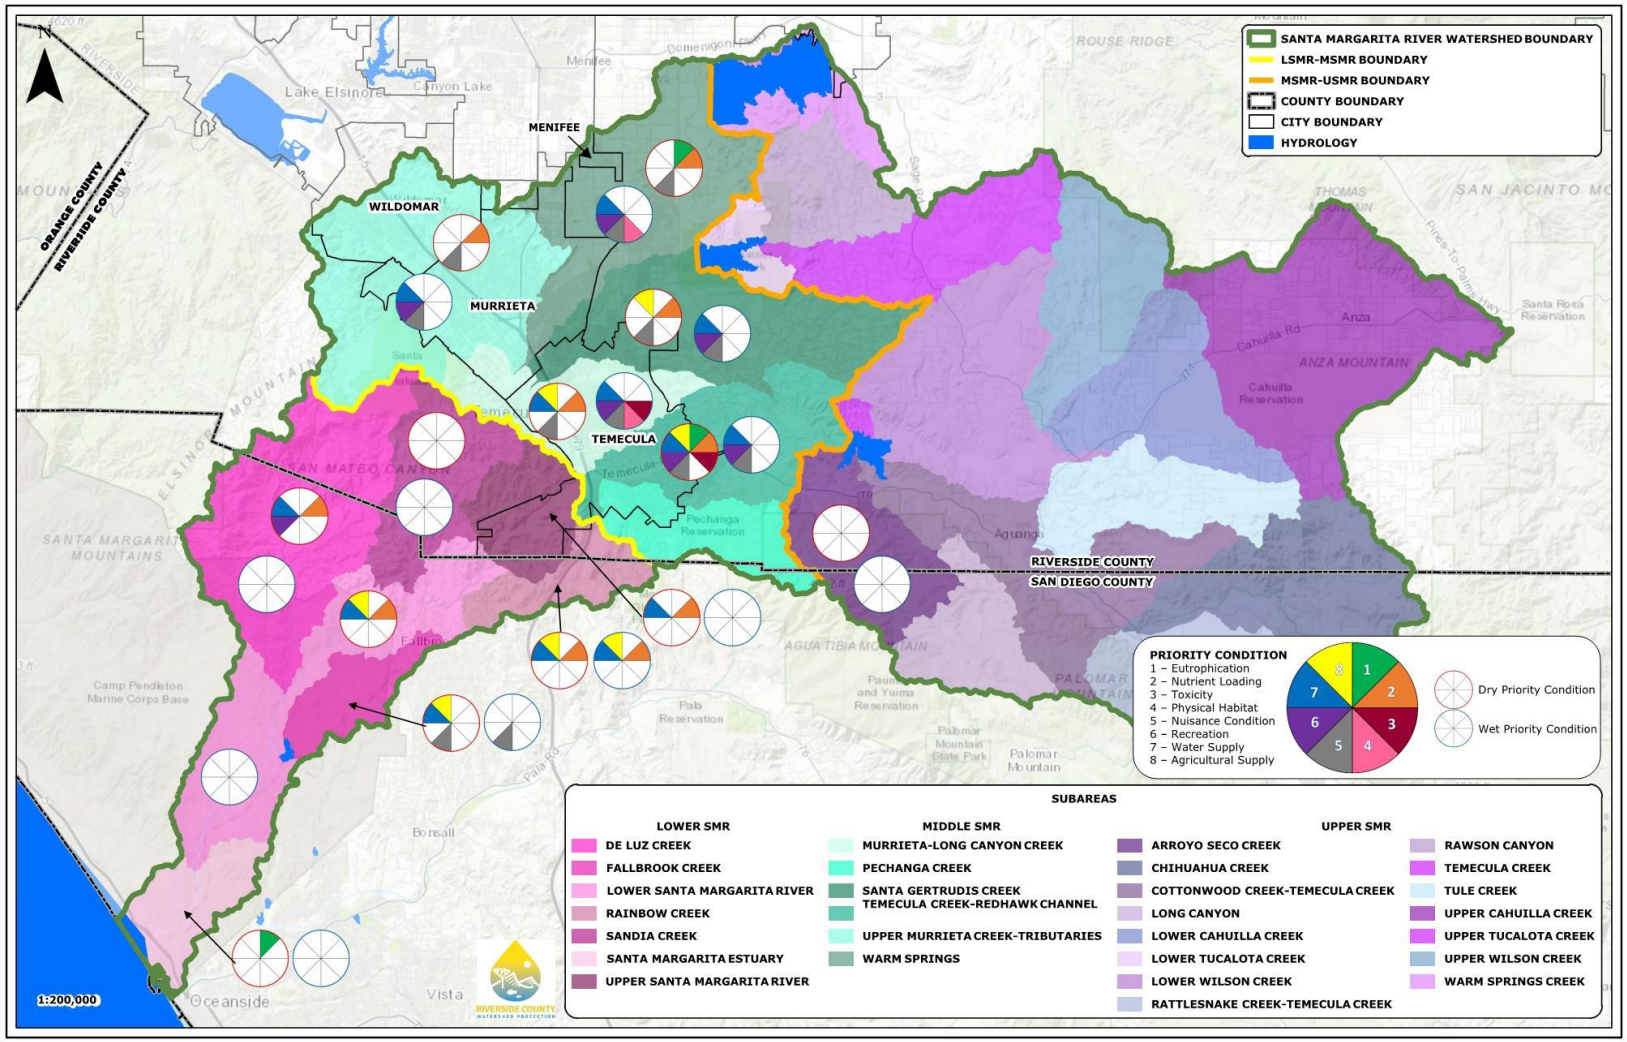

Figure 2-13. Priority Water Quality Conditions in the SMR WMA

2.5.2 Monitoring Data Adequacy and Data Gaps (Provision B.2.c.(1)(e))

Data gaps were evaluated for the SMR WMA analyses of receiving water conditions and potential impacts from discharges from MS4 outfalls.

Receiving water conditions were found to have data gaps for specific analyses, particularly for:

- Biological indices;
- Toxicity;
- Algal biomass; and
- Physical habitat.

Other datasets for receiving water assessments (e.g., chemistry) were adequate to assess receiving waters conditions in the Lower and Middle SMR Subwatersheds. However, recent receiving water data were not available for the Upper SMR Subwatershed.

Data to characterize MS4 discharges is spatially limited, particularly in the Middle SMR Subwatershed. Thus, MS4 outfall data is a limiting factor in gaining a comprehensive understanding of the MS4 contribution to watershed conditions.

Streams in the Middle SMR Subwatershed are predominantly ephemeral or intermittent. In many cases, site visits indicated that receiving waters, especially in the Middle SMR Subwatershed, were dry. Receiving water and outfall sites that were observed to be dry during site visits are indicated by a designation of "visited not sampled" or VNS. The percentage of time that a site was dry during site visits is shown in **Figure 2-14**. The limited data resulting from the ephemeral or intermittent nature of the watershed drainage network constrains the ability to fully assess MS4 impacts on receiving waters.

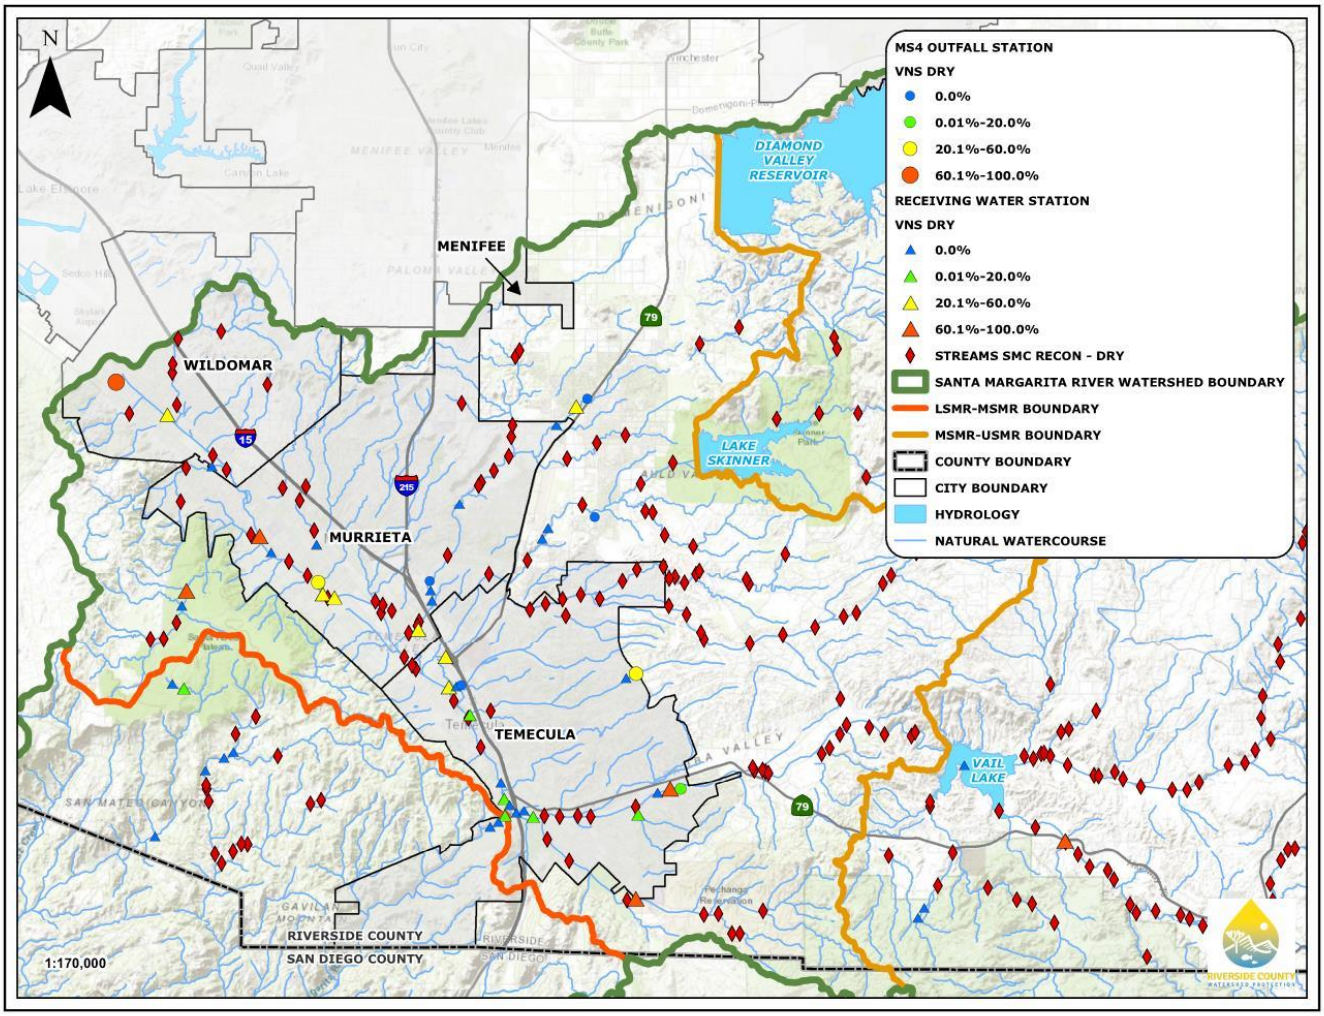

Figure 2-14. Reaches and Receiving Water Monitoring Locations within the Upper and Middle Santa Margarita River Subwatersheds and Monitored Flow Conditions (Perennial to Dry)

VNS = Visited Not Sampled (dry or discontinuous channel or outfall)

As a part of the development of goals, strategies, and the monitoring program, data gaps will be further evaluated by identifying specific questions to support assessment of watershed conditions and implementation to address PWQCs. In addition, work that could address some data gaps may be conducted as part of the SMRNIG should grant funds be available.

2.6 STEP 5B. HIGHEST PRIORITY WATER QUALITY CONDITION (PROVISION B.2.C.(2))

The HPWQC to be addressed by the WQIP (**Table 2-34**) was selected from the list of PWQCs by evaluating them against a set of ten considerations outlined in **Table 2-33**.

- The first seven considerations include many of the components evaluated in Prioritization Steps 1-4. The existence of a TMDL/significant regulatory action, impaired waters 303(d) listing, current WQO and threshold exceedances, as well as historic conditions, location, and geographic extent of the conditions were all taken into account.
- The last three considerations include potential improvements in condition of waterbodies in the WMA and MS4 discharge quality that can be achieved as stated in Permit Provisions B.2.a.(9) and B.2.b.(6) in the Permit.

Each of the PWQCs was given a binary score of 1 if it met the consideration or 0 if it did not. These scores were then summed to give a final score to each of the PWQCs out of a highest possible score of 10. These total scores were then used to rank the PWQCs such that the highest score determined the HPWQC.

Based on the assessment of HPWQC considerations, eutrophication was selected as the HPWQC (See **Table 2-34**) in comparison to other PWQCs. In general, the scoring reflects the limited geographic scope of other PWQCs and the lack of evidence of beneficial use impacts, combined with limited availability of technology available to effectively treat all constituents affecting recreation, water supply, and agricultural supply.

Given the 303(d) listings, the existing TMDL, and the TMDL Alternative under development for nutrients and biostimulatory substances that cover most subareas in the Middle and Lower Subwatersheds, the potential impact on aquatic life from those conditions, and the threshold exceedances observed in those subareas, eutrophication is the clear HPWQC for the Middle and Lower SMR Subwatersheds. The eutrophication HPWQC includes all subareas with observed eutrophication impacts (elevated algal biomass and impacted benthic scores), dry weather nutrient loading to those subareas to address the eutrophication, and dry and wet weather nutrient loading to Rainbow Creek to address the Rainbow Creek Nutrient TMDL.

The intent of the WQIP is to address the HPWQC identified through this prioritization process. As implementation progresses and more information is collected to support the prioritization process, the Copermittees and the City of Menifee could determine that other watershed conditions are of a higher priority or that addressing an identified priority may not result in the most beneficial or cost-effective way to protect beneficial uses. If this were to occur, the Copermittees and the City of Menifee may choose to change their focus, and potentially adjust their priorities, as part of the adaptive management process.

Table 2-33. Summary of Rationale for Selection of Highest Priority Water Quality Conditions

Beneficial Use Category	Aquatic Life			Aquatic Life/ Rec.			
Considerations	Eutrophication	Toxicity	Physical Habitat	Nuisance (Trash)	Recreation	Water Supply	Agricultural Supply
TMDL existing/under development (Permit Provision 2.a.(2)) or significant regulatory action	**1**			1			
303(d) Listing (Permit Provision 2.a.(1))	**1**	1			1	1	1
Threshold exceedances (to assess Permit Provision 2.a.(4)-Receiving Water Limitation, Permit Provision 2.a.(6)-analysis of physical, chemical, and biological Receiving Water data, Permit Provision 2.a.(8)-evidence adverse impacts to waterbody integrity):							
Current WQO exceedances (water chemistry)	**1**	1			1	1	1
Current threshold exceedances (other indicators) or evidence of impacts (Permit Provision 2.a.(7))	**1**		1	1	1		
Known historical compared to current conditions (Permit Provision 2.a.(5)) (increasing trends)	**1**						
Known locations of potential beneficial use impacts	**1**	1	1		1		
Geographic extent (majority of subareas have PWQC)	**1**			1	1	1	
Assessment of potential improvements in condition of WMA and MS4 discharge quality that can be achieved (Permit Provisions 2.a.(9) and 2.b.(6)) based on score from following questions:							
Feasible projects or programs that could be considered to improve PWQCs?	**1**	1	1	1	1		
If PWQCs are improved through actions taken by the Copermittees, would opportunities related to the beneficial use be realized?	**1**	1	1	1			
Are there other social benefits gained by restoring the beneficial uses?	**1**	1	1	1	1		
Total	**10**	6	5	6	7	3	2

Table 2-34. Highest Priority Water Quality Condition (Eutrophication)

Beneficial Use Category	Priority Water Quality Condition	Temporal Extent	Geographic Extent
Eutrophication	Eutrophication impacts (elevated algal biomass)	Dry	SMR Estuary [1], Warm Springs, Redhawk Channel [2]
	Nutrient loading to waterbodies with an adopted TMDL or listed as impaired	Dry	All Middle and Lower SMR subareas, except Fallbrook Creek and Sandia Creek[1]
		Wet	Rainbow Creek

1. MS4 discharges within the following subareas may reach the SMR Estuary during dry weather and contribute to the Eutrophication PWQC in the Santa Margarita River Estuary: Upper Murrieta Creek and Tributaries, Warm Springs, Santa Gertrudis, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Lower Santa Margarita River, Rainbow Creek and De Luz Creek.
2. Other subareas may be added as result of TMDL Alternative development during adaptive management process.

The geographic extent of the HPWQC is shown in **Figure 2-15**.

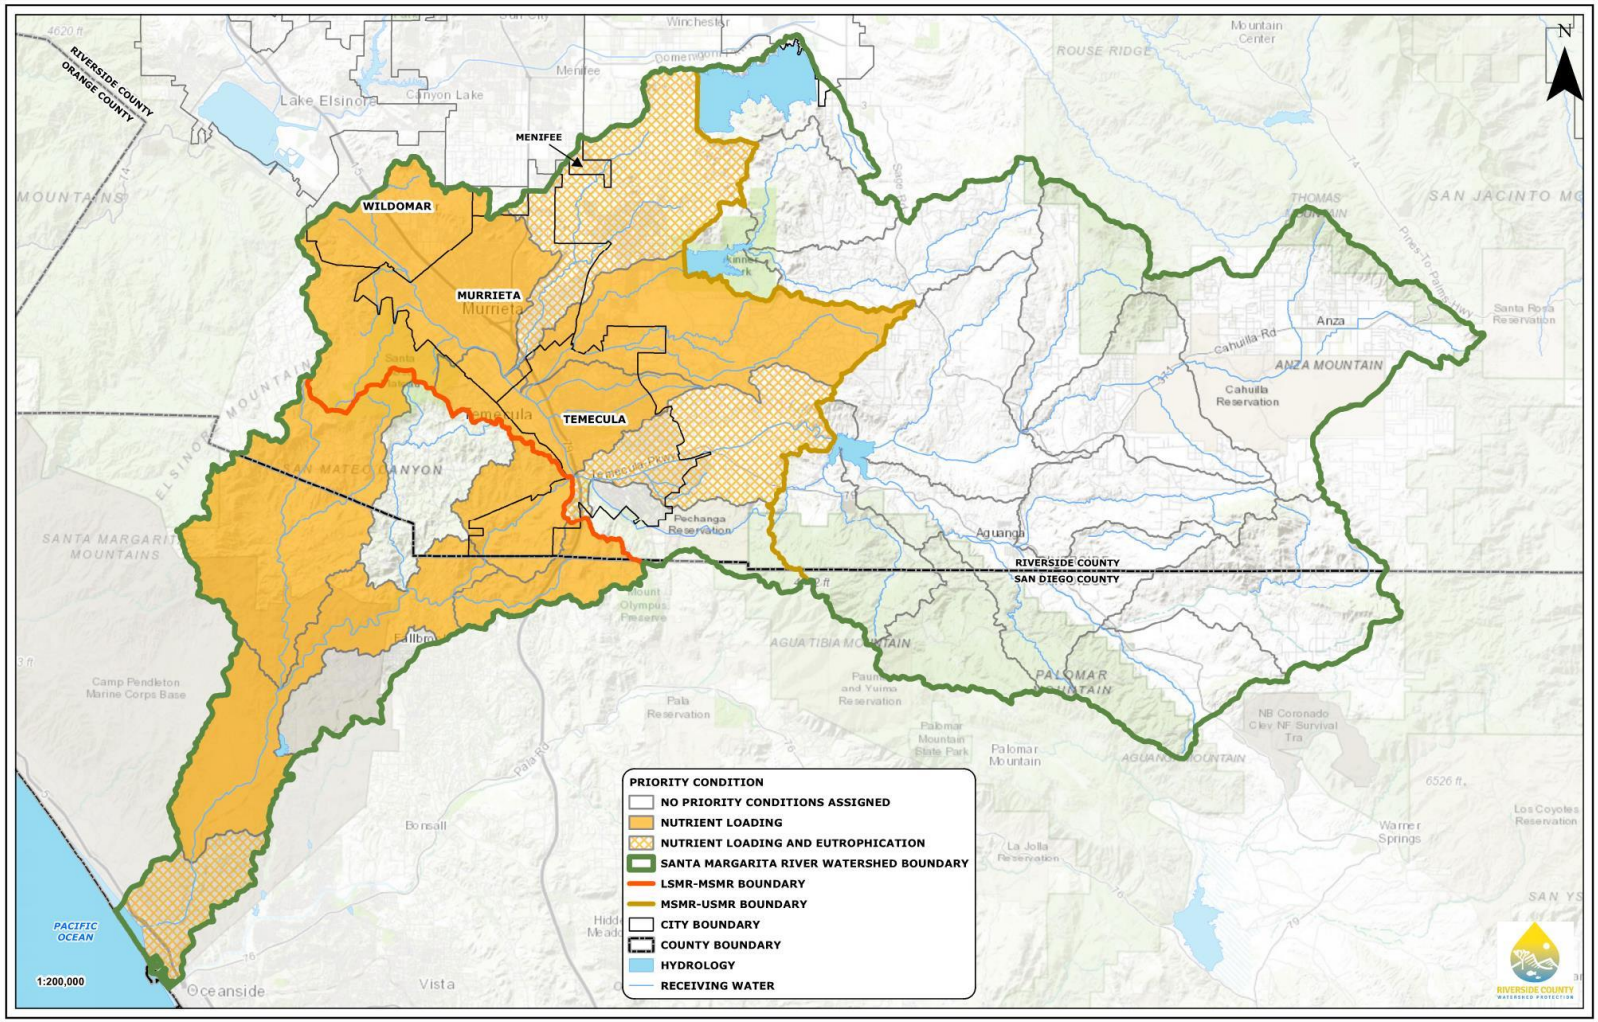

Figure 2-15. Geographic Extent of HPWQC

3 Identification of MS4 Sources of Pollutants and/or Stressors

As a part of the WQIP, the Copermittees must "identify and prioritize known and suspected sources of stormwater and non-stormwater pollutants and/or stressors associated with discharges that cause or contribute to the highest priority water quality conditions". The purpose of the source identification is to evaluate the presence or absence of key sources within the watershed that have the potential to contribute to the HPWQC. The results of the source identification will drive the selection of strategies designed to address these sources, and thereby address the HPWQC. As part of this effort, the following was considered:

- Pollutant generating facilities, areas, and/or activities within the watershed;
- Locations of the Copermittee's stormwater conveyance systems;
- Other known and suspected sources of non-stormwater or pollutants in stormwater discharges to receiving waters within the watershed;
- Review of available data; and
- Adequacy of available data to identify and prioritize sources and/or stressors associated with discharges from MS4 outfalls.

The items listed above were used to identify pollutants and stressors that potentially contribute to the identified HPWQC (eutrophication impacts/nutrient loading). This Plan considers watershed conditions and priorities in the context of the Copermittees' obligations to control MS4 discharges, and the evaluation of potential sources of the HPWQC focuses on MS4 discharges. For sources outside of the regulatory authority of the Copermittees and those impacting water quality within the WMA, the Copermittees may consider opportunities to collaborate with other entities to control the sources. Sources described in this section are not exhaustive, but are generally representative of the types of sources present within the WMA. Reducing nutrient loading from watershed sources will address both elements of the HPWQC – eutrophication impacts (elevated algal biomass) and nutrient loading to TMDL waterbodies.

The identification of sources begins with considering land uses but includes many types of other source information to identify areas and activities within the watershed that contribute total nitrogen and total phosphorus loading to the MS4 . The distribution (in acreage) of land uses (i.e., agriculture, commercial, industrial, etc.) for each agency are shown in **Table 3-1** and the land uses within the watershed are shown in **Figure 3-1**.

Table 3-1. Santa Margarita River WMA Land Use (acre) by Agency [a]

Type of Land Use [b]	City of Menifee	City of Murrieta	City of Temecula [c]	City of Wildomar [d]	County of Riverside	Riverside County Flood Control and Water	County of San Diego	Total	% of Land Use
Agriculture	0	295	0	297	21,953	0	5,389	27,934	5.9%
Commercial	8	1,028	1,476	164	884	0	112	3,672	0.8%
Industrial	0	227	1,075	40	136	0	51	1,529	0.3%
Open space	115	3,941	6,980	2,971	42,660	0	3,100	59,767	12.6%
Parks and Recreation	<1	598	794	105	1,083	0	30	2,610	0.6%
Rural Residential	585	7,185	3,408	2,910	105,475	0	6,144	125,707	26.5%
Urban Residential	35	4,919	5,947	1,586	2,956	0	839	16,282	3.4%
Streets	72	6,468	3,248	908	8,020	0	548	19,264	4.1%
>>>Total	815	24,661	22,928	8,981	183,167	0	16,213	256,763	

a. Other land uses not within the Agencies' jurisdictions comprise the remaining percentage (37%) of land uses found within the Upper, Middle and Lower Santa Margarita River Subwatersheds, totaling 156,185 acres. These land uses are comprised of federal and tribal lands, as well as vacant, undeveloped land, and waterbodies.

b. Land use Sources: Riverside County – July 2017 County Assessor Parcel Data; San Diego County, 2017 SANDAG.

c. Please note the City does not have any land uses zoned for agricultural. However agricultural operations are allowed on all residentially zoned land uses. All commercially operated agricultural operations within the city require a business license and the city uniquely identifies these in its business license inventory. There are currently no commercially operated vineyards or orchards within City limits. "Temecula Wine Country" is located outside Temecula City Limits

d. Only includes land use data within the Santa Margarita River watershed

e. Facilities owned and operated by RCFCWCD, and their respective acreage, are included in **Table 3-3** and illustrated in **Figure** 3-3.

Residential land uses (29.9%) comprise the largest proportion of land use within the jurisdiction of the Copermittees, followed by open space (12.6%). Commercial and industrial together make up about 1% of the total SMR WMA. Agriculture comprises 5.9% of land use in both subwatersheds. Forty-six percent of the land use is comprised of federal and tribal lands, as well as vacant, undeveloped land and waterbodies outside of the Copermittees jurisdiction. **Figure 3-1** illustrates the distribution of land uses within the SMR watershed.

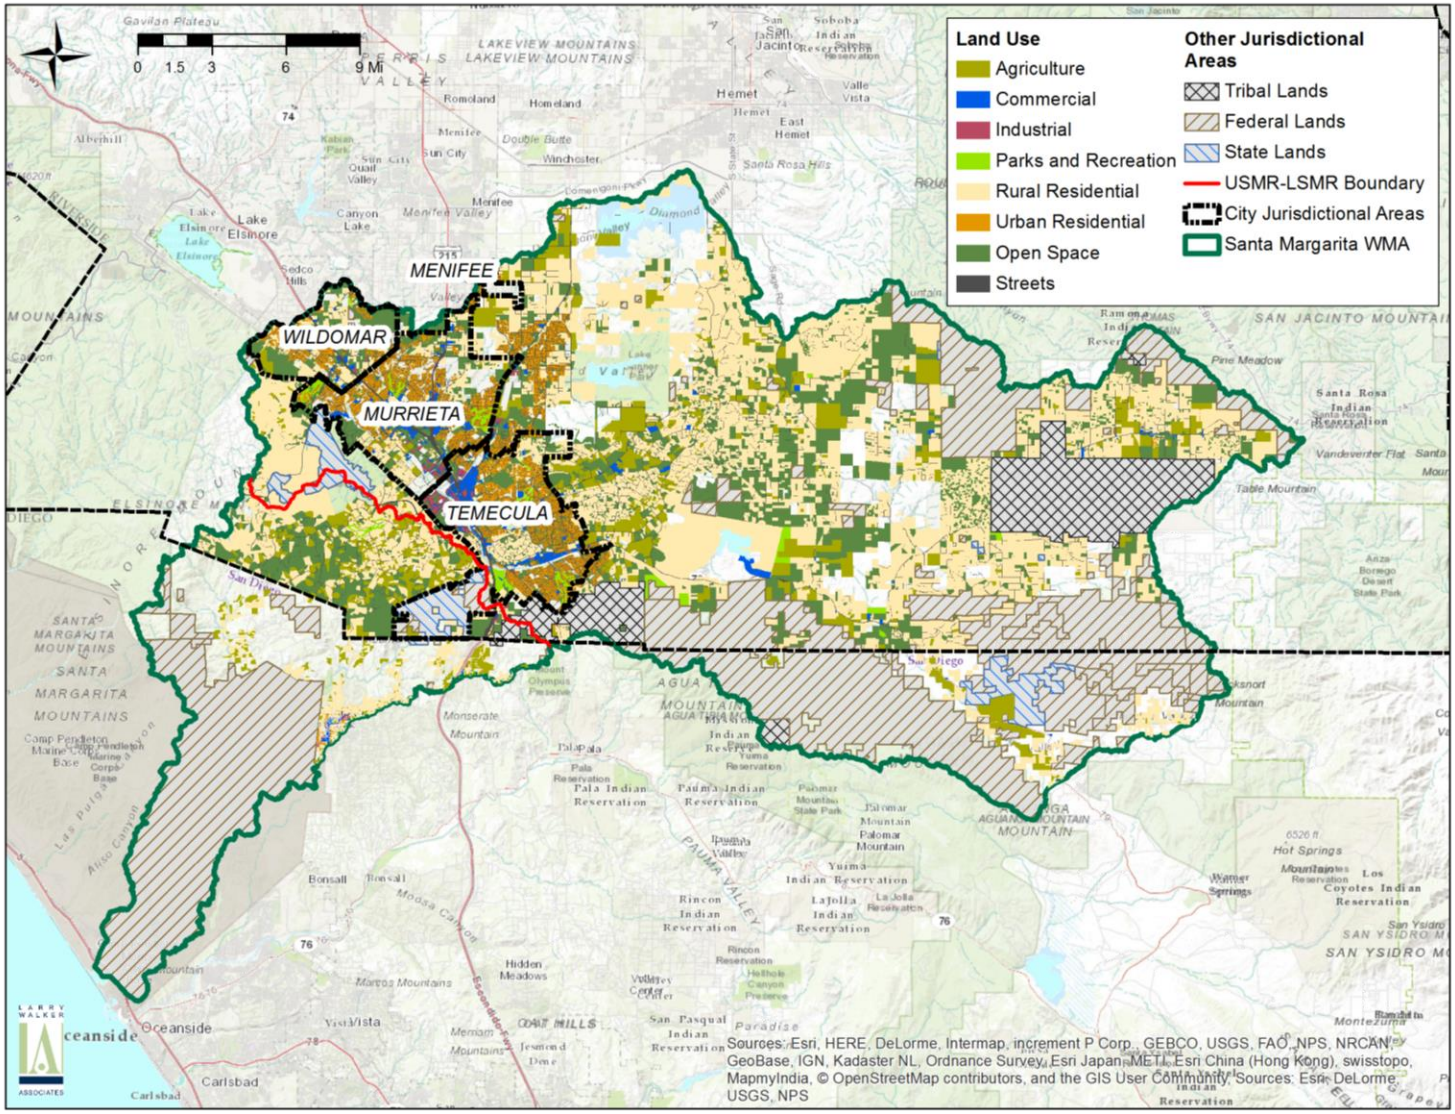

Figure 3-1. Land Uses within Santa Margarita River Watershed

3.1 POLLUTANT GENERATING FACILITIES, AREAS, AND/OR ACTIVITIES

The Copermittees and the City of Menifee considered pollutant generating facilities, areas, and/or activities within the watershed, including, but not limited to, the following:

1. Each agency's inventory of construction sites, commercial, industrial, and municipal facilities, and residential areas;
2. Publicly owned parks and/or recreational areas;
3. Open space areas;
4. All currently operating or closed municipal landfills or other treatment, storage or disposal facilities for municipal waste; and
5. Areas not within the agencies' jurisdictions (e.g., Phase II MS4, tribal lands, state lands, federal lands) that are known or suspected to discharge to MS4s.

3.1.1 Pollutant Generating Facilities, Areas, and Activities

The Copermittees and the City of Menifee maintain a list of construction sites, commercial, industrial, and municipal facilities, and residential areas that can be used to assist in identifying areas that have the potential to contribute nutrient loading to receiving waters. During dry weather, pollutants from these potential sources may reach the MS4 through illicit discharges or illegal dumping.

- All Copermittees and the City of Menifee maintain construction inventories within their jurisdictions, which can span the various types of land uses across the watershed. There is the potential for sediment discharges, primarily during the rainy season, which could transport phosphorus or other pollutants to the MS4. In particular, sites that are being converted from prior agricultural land uses may warrant specific attention when in active construction.
- Commercial sites include existing development such as restaurants, nurseries, car washes, auto repair shops, and other facilities. Based on activities at these sites and the nature of their operations, some commercial sources may be sources of nutrients (e.g., nurseries, restaurants). Restaurants and nurseries are more likely to be sources of illicit discharges due to their onsite activities (e.g., illegal washing, tail water), while any of the sites that have landscaping could contribute to nutrient loading through irrigation runoff. While they only represent approximately 1% of the land use within the watershed, commercial facilities are concentrated more in the Cities of Murrieta and Temecula and the County of Riverside than in other areas. As illustrated in **Figure 3-2**, there are very few commercial nurseries within the incorporated areas of the watershed.
- Industrial sites include, but are not limited to, manufacturing and large-scale production facilities. These sites are generally regulated through other permits (e.g., Industrial General Permit), typically have materials stored inside, and are not as likely to have illicit discharges as a result of their typical activities and operations. However, as with other facilities, those with landscaping could contribute to nutrient loading through irrigation runoff. Industrial facilities are not common within the watershed, representing <1% of the land use.

- Municipal sites include, but are not limited to, municipal buildings, offices, maintenance yards, parks, community centers, fire stations, and libraries. While these sites are not as likely to contribute nutrients through their activities, any of them with landscaping could contribute to nutrient loading through irrigation runoff. This may be particularly applicable to municipal parks, where there tends to be more grass, landscaping, and irrigation. Parks and recreation facilities only represent approximately 1% of the land use within the watershed.
- Residential areas within the watershed are the predominant land use within the agencies' jurisdictions, comprising approximately 30% of the land use within the watershed. These areas have several potential activities that could contribute to nutrient loading including, but not limited to, landscape irrigation and overwatering, small "backyard" agricultural operations, and equestrian uses.

Table 3-2 presents the current inventory of active commercial, industrial, construction, and municipal sites within the agencies' jurisdictions. The RCFCWCD does not have any commercial, industrial, or municipal sites; therefore, its facilities are summarized in **Table 3-3**.

Table 3-2. Summary of Applicable Pollutant Generating Facilities, Areas, and/or Activities by Agency within the Santa Margarita River Watershed.

Potential Pollutant Generating Sites	City of Menifee	City of Murrieta	City of Temecula[1]	City of Wildomar[3]	County of Riverside	County of San Diego	Riverside County Flood Control and Water Conservation District
Construction Sites	0	31	92	32	112	63	9[2]
Commercial Sites	3	267	648	52	196	153	0
Industrial Sites	0	6	126	2	52	18	0
Municipal Sites	0	65	53	5	43	8	0

1. Number of construction sites determined by active Construction Notices of Intent obtained from SMARTS on December 05, 2017.
2. Construction sites are listed pursuant to encroachment permits issued by the RCFCWCD or federal agreement and are not RCFCWCD projects.
3. Only within the Santa Margarita River watershed.

Table 3-3. Summary of Facilities Owned and Operated by Riverside County Flood Control and Water Conservation District

Type of Facility	Description
Linear Facilities (e.g., storm drains, channels)	435,180 linear feet (82.4 linear miles)
Basins (1 retention basin, 1 detention basin, 1 desilting basin)	3 facilities (15 acres)
Owned Parcels (e.g., basins, channels, access roads)	836 acres[1]

1. The RCFCWCD maintains the as-built capacity/lines and grades of existing flood control facilities within the 836 acres. Maintenance activities include sediment and debris removal, slope and erosion repairs, side-slope tracking and/or reshaping, vegetation maintenance, structure rehabilitation and/or replacement, rip-rap and grout repair, removal and replacement of concrete channel linings, and washout backfill and repair.

Figure 3-2 shows the location and distribution of commercial and industrial facilities within the Upper, Middle, and Lower SMR Subwatersheds based on inventories maintained by each Copermittee. Where available within inventories, the figure includes specific types of commercial facilities identified as potential sources of nutrient loading including orchards, vineyards, nurseries, and horse ranches. The RCFCWCD's facilities are illustrated in **Figure 3-3**. Additional information regarding potential commercial and industrial sources within the Lower SMR Subwatershed can be found in the Long-Term Effectiveness Assessment. (San Diego Stormwater Copermittees, 2011) Available watershed-specific loading information related to these sources is also discussed below in **Section 3.3**.

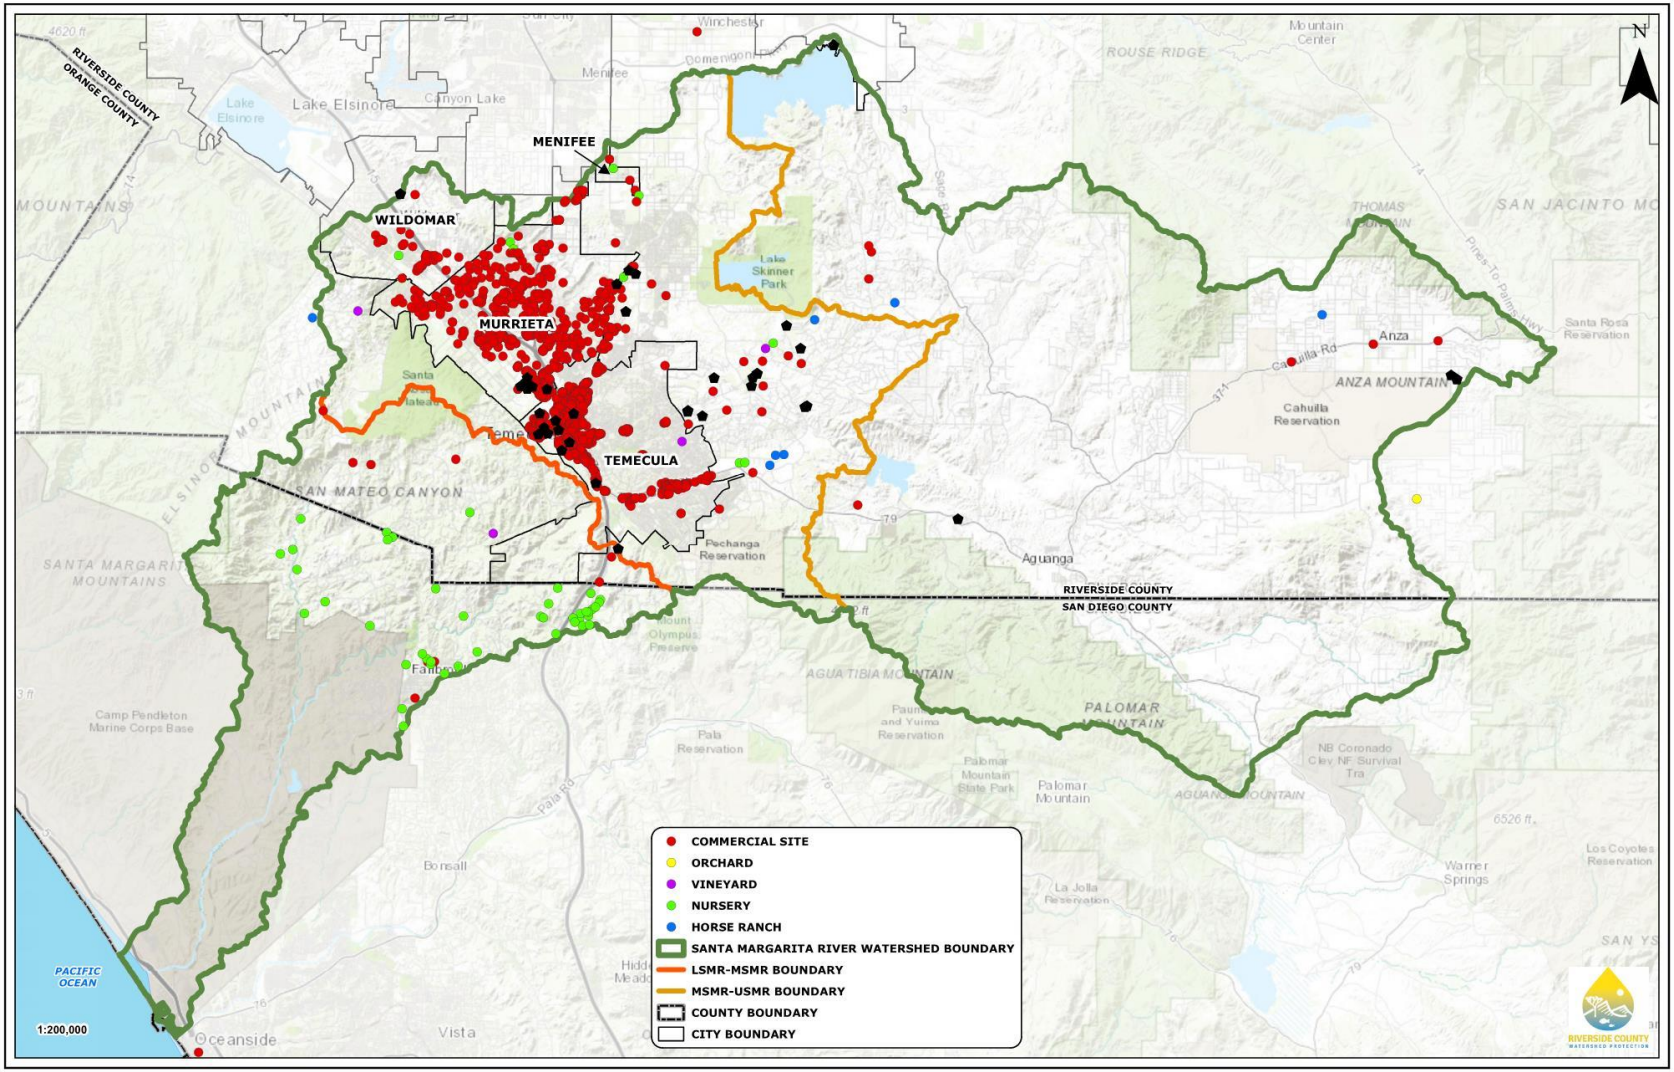

Figure 3-2. Location and Distribution of Commercial and Industrial Facilities within the Santa Margarita River Watershed

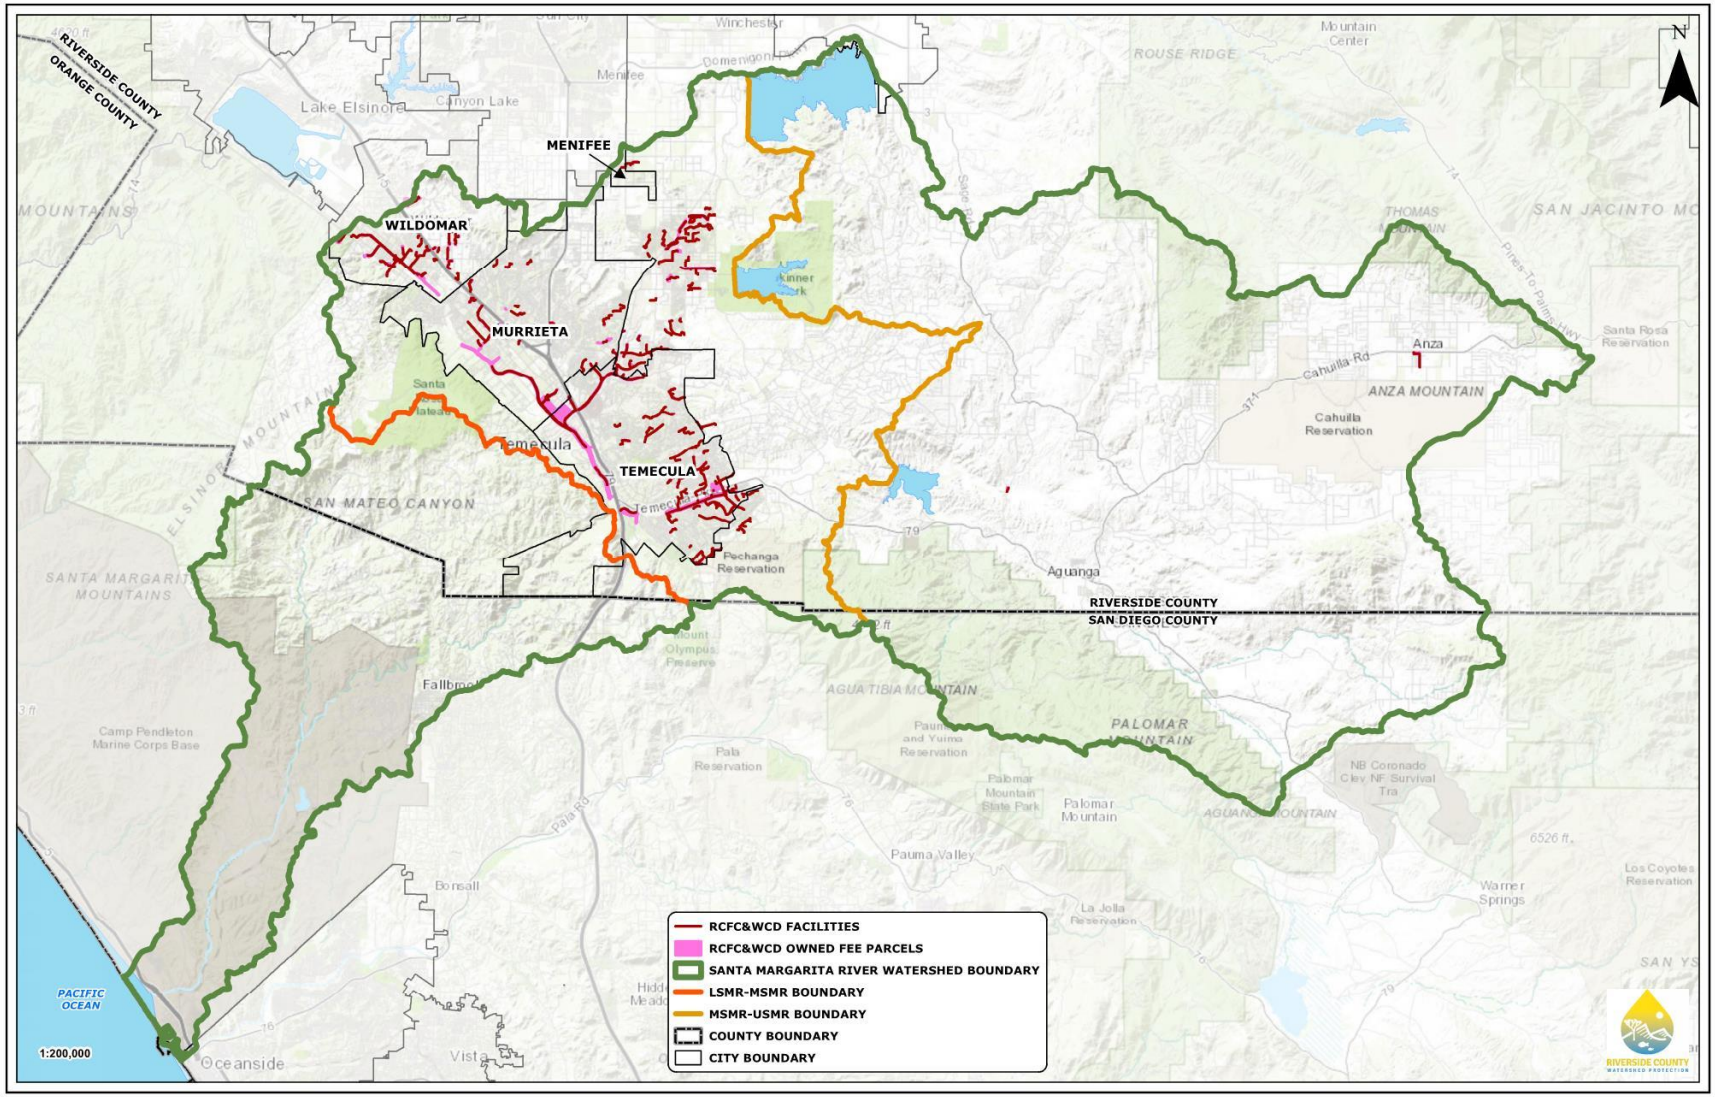

Figure 3-3. Location and Distribution of RCFCWCD Facilities within the Santa Margarita River Watershed

3.1.2 Parks, Recreational and Open Space Areas

Publicly owned parks and/or open space areas make up 13% (62,377 acres) of the SMR WMA. Overall, the area of individual parks within the agencies' jurisdictions is small (2,610 acres) as compared to the overall extent of open space throughout the watershed as a whole (59,767 acres). Parks and open space are summarized by jurisdiction in **Table 3-3**.

Table 3-4. Summary of Parks and Open Space Areas within the SMR WMA

Agency	Number of Parks	Acres of Open Space[2]
City of Menifee	0	115
City of Murrieta	50	3,941
City of Temecula	40	6,980
City of Wildomar[1]	2	2,971
County of Riverside	22	42,660
County of San Diego	1	3,100
RCFCWCD	0	0

1. Only includes land use data within the SMR Watershed.
2. Land use Source: July, 2017 County Assessor Parcel Data; 2017 SANDAG.

Open space and parks contribute to the nutrient loading for all jurisdictions included in the model analysis, further discussed in **Section 3.3**. The predicted nutrient loads from municipal parks and recreation areas are relatively low, between 0 to 2.5% of the overall nutrient loading from the MS4s, depending on the jurisdiction. Although loading from parks is estimated to be a small part of the overall nutrient load from the watershed, this may be due to the limited acreage of parks within the watershed. Because parks can be a source of nutrients and are often owned and maintained by the Copermittees, the Copermittees have developed strategies to address potential nutrient loading from these areas.

3.1.3 Landfills or Other Treatment Facilities for Municipal Waste

There are four operating or closed municipal landfills or other treatment, storage or disposal facilities for municipal waste within the agencies' jurisdictions; one located in the City of Temecula, one in the City of Wildomar (closed), one in the County of Riverside (closed), and one in the County of San Diego. There are no landfills or other treatment facilities for municipal waste within the Cities of Menifee, Murrieta, or the Riverside County Flood Control and Water Conservation District. Due to their relatively low numbers and significant regulation, these facilities are not expected to be significant sources of nutrient loads to the MS4s. Landfills in the watershed are summarized in **Table 3-5**.

Table 3-5. Number of Landfills or Other Treatment Facilities for Municipal Waste within the Santa Margarita River Watershed

Agency	Number of Landfills or Other Treatment Facilities for Municipal Waste
City of Menifee	0
City of Murrieta	0
City of Temecula	1
City of Wildomar	1[1]
County of Riverside	1[2]
County of San Diego	1
RCFCWCD	0

1. Site is closed (Bundy Canyon Landfill is partially located within the SMR watershed).
2. Site is closed (Anza).

3.1.4 Areas not Within the Agencies' Jurisdictions

Tribal lands, federal lands, state parks, and lands regulated by the State Water Board or USEPA may be located within an agency's boundary, but are outside of the jurisdictional land use authority of the agency. Regardless, each of these land uses has the potential to contribute to nutrient loading. Where these areas contribute pollutants to a Copermittee's MS4, the Copermittee will work with the land owner to ensure that any illicit discharges cease and/or notify the permitting authority. In general, while models do predict that nutrient loads from these sources could impact receiving waters, the amount of loading from these land uses entering and, therefore, discharging from Copermittees' MS4ss is very low. Specific loading predictions from these sources are further discussed in **Section 3.3**. As illustrated in **Table 3-1**, there are significant areas of land within the watershed that are outside of the Copermittees' jurisdictions, including tribal lands, state lands, and federal lands. In the Upper, and Middle SMR Subwatersheds, these areas account for approximately 70,000 acres or 20% of the land area. In the Lower SMR Subwatershed, these areas occupy approximately 60% of the land area, totaling over 40,000 acres.

3.1.5 Location of the Agencies' Stormwater Conveyance Systems

The Copermittees identified and mapped the locations of their stormwater conveyance systems, including, but not limited to, the following:

1. All MS4 outfalls that discharge to receiving waters; and
2. Locations of major structural controls for stormwater and non-stormwater (e.g., retention basins, detention basins, major infiltration devices, etc.).

The locations of the 345 major MS4 outfalls within the watershed are shown in **Figure 3-4** and the locations of major structural controls are illustrated in **Figure 3-5**. The figures were developed based on 2017 data provided by each Copermittee. **Table 3-6** presents the number of major structural controls for stormwater and non-stormwater by agency.

Table 3-6. Number of Major Structural Controls for Stormwater and Non-Stormwater Within Agencies' Jurisdictions Within the Upper & Middle SMR Subwatersheds.

Structural BMP	City of Menifee	City of Murrieta	City of Temecula [1]	City of Wildomar	County of Riverside [2]	County of San Diego [3]	Riverside County Flood Control and Water Conservation District
Retention Basins	0	11	21	0	0	0	1
Detention Basins	0	18	11	3	4	0	1
Infiltration BMPs	4	34	74	0	9	0	0
Other major Structural Controls	0	0	505	0	7	0	1
Total Number of Structural BMPs	**4**	**63**	**611**	**3**	**20**	**0**	**3**

1. Tabulation of Structural BMPs does not include over 100,000 square feet of porous asphalt or pervious pavers.
2. Number of sites containing post-construction BMPs is provided. Each site may have multiple BMPs.
3. No major, publicly-owned and operated structural controls within the County of San Diego's jurisdiction in the Lower SMR Subwatershed.

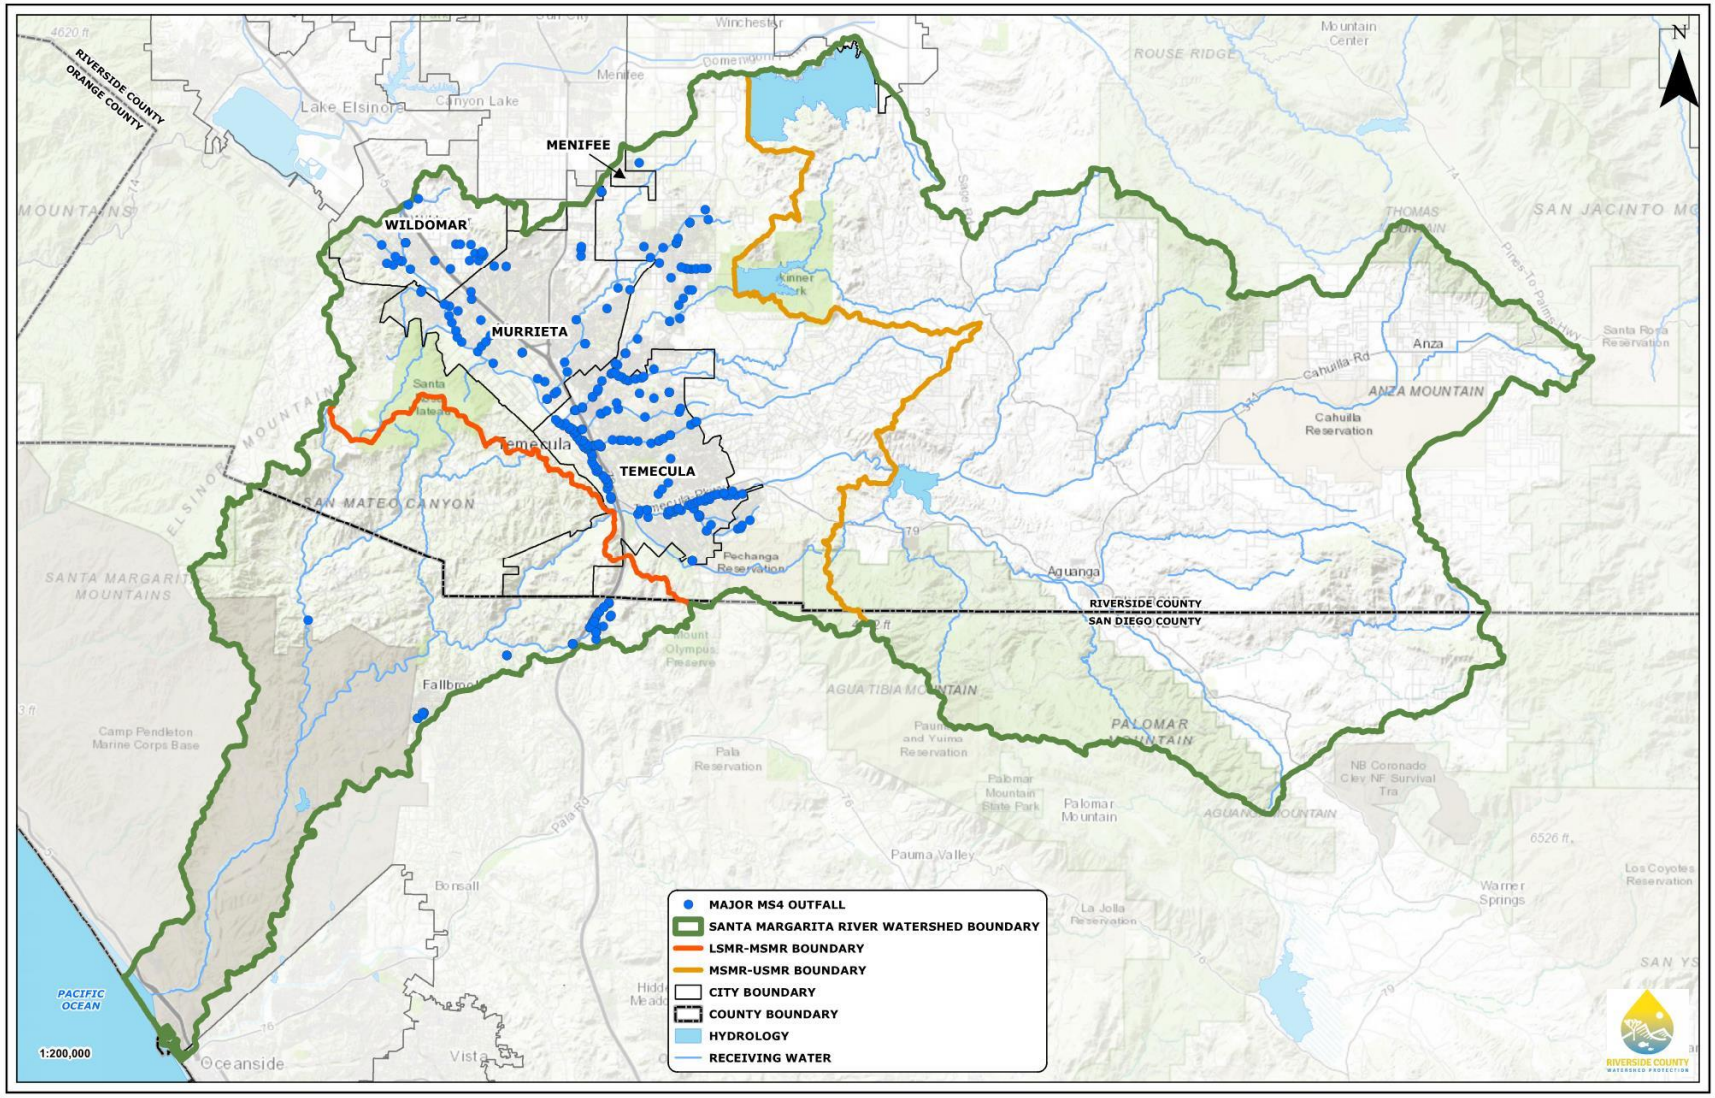

Figure 3-4. Locations of Major MS4 Outfalls within the Santa Margarita River Watershed

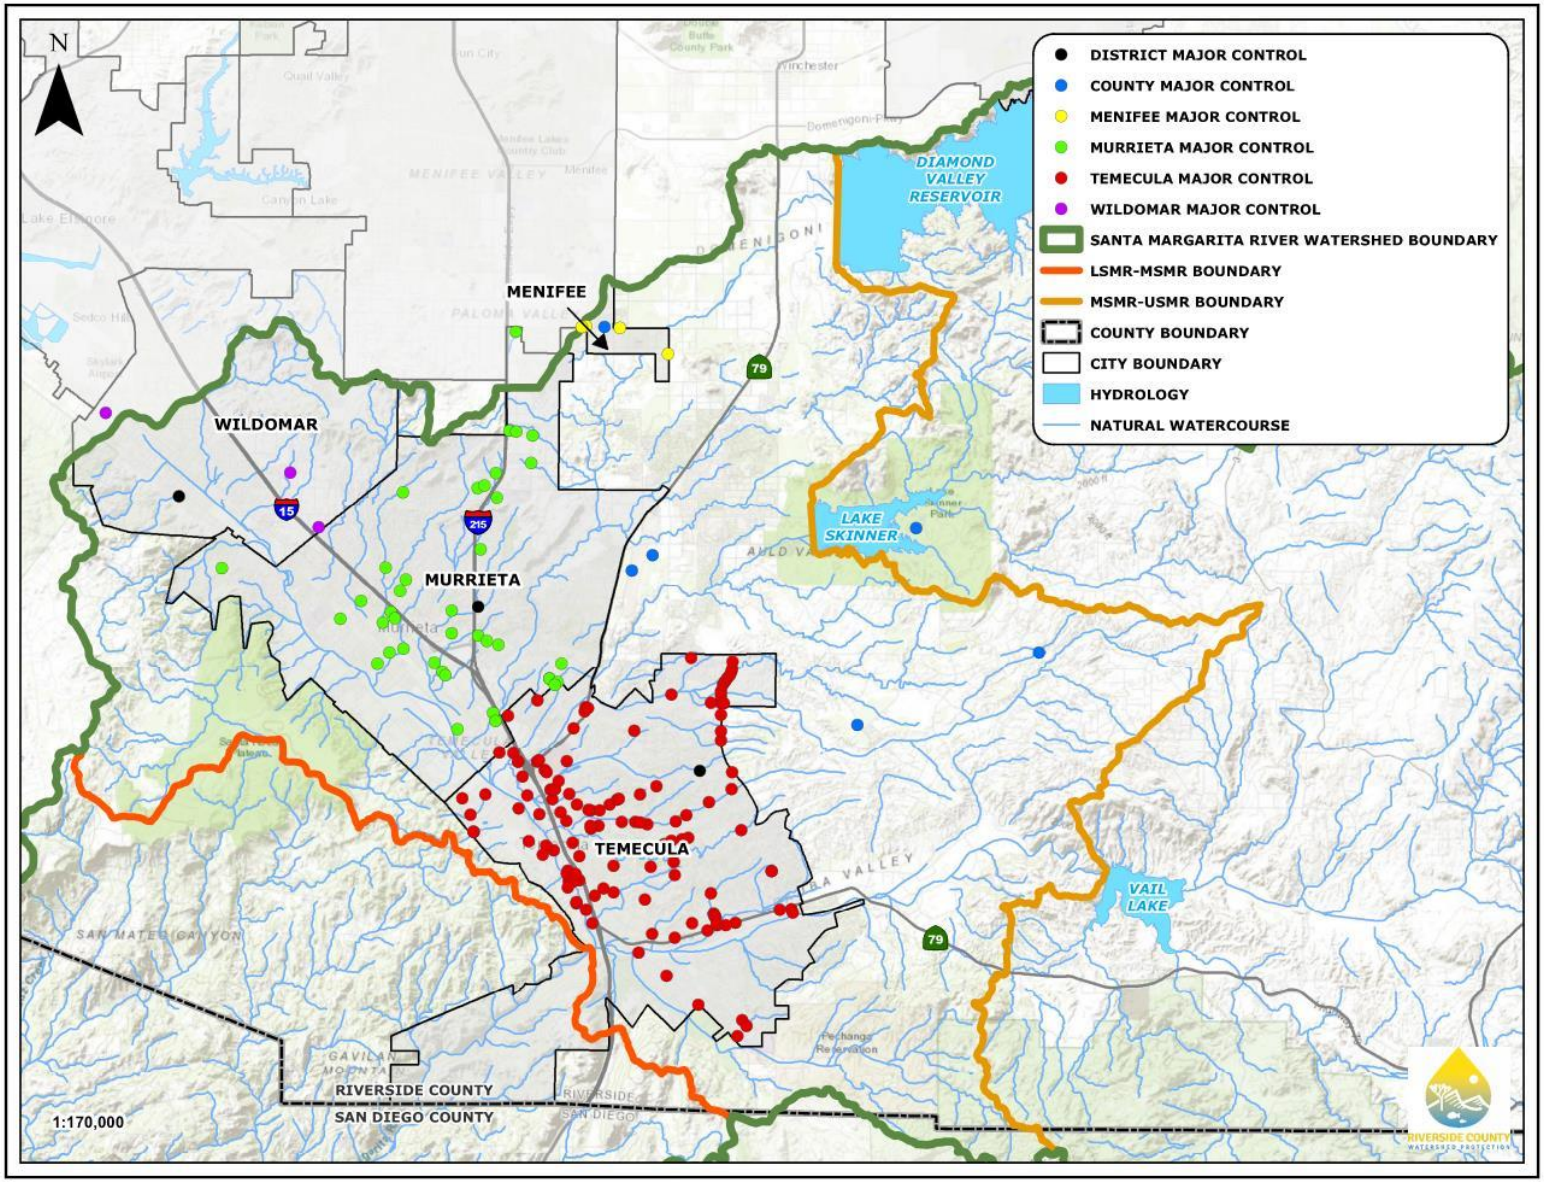

Figure 3-5. Locations of Major Structural Controls Locations within the Santa Margarita River Watershed

3.2 OTHER POTENTIAL SOURCES

Other known and/or suspected sources of non-stormwater discharges or pollutants in stormwater discharges to receiving waters within the watershed, including, but are not limited to, the following:

- Other MS4 outfalls (e.g., Phase II and Caltrans);
- Other NPDES permitted discharges;
- Any other discharges that may be considered point sources (e.g., private outfalls); and
- Any other discharges that may be considered non-point sources (e.g., agriculture, wildlife or other natural sources).

3.2.1 Other MS4 Outfalls

In addition to discharges from areas not within the agencies' jurisdictions as discussed in **Section 3.1.4**, there are entities covered by NPDES Permits issued by the State Water Board, including the Phase II MS4 Permit (California State Water Resources Control Board, 2013) and the Caltrans MS4 Permit (California State Water Resources Control Board, 2012b).

There are no traditional or non-traditional Phase II facilities within the Upper and Middle SMR Subwatersheds. Camp Pendleton, which is located on federal land in the Lower SMR Subwatershed, is currently the only non-traditional Phase II entity in the SMR WMA that is regulated under the Phase II MS4 Permit. Nutrient loading from Camp Pendleton is relatively small and does not discharge to Copermittee-owned MS4s, however, their discharges may impact conditions in the SMR Estuary and they do participate in watershed management activities with the Copermittees through the SMRNIG. For example, there are fallow agricultural fields (i.e., Stuart Mesa) on Camp Pendleton that may contribute nutrient loading to the estuary. Models developed by the SMRNIG have estimated nutrient loading from Camp Pendleton as illustrated in Figure 3-6.

Caltrans does own and operate state highways within the watershed and associated MS4 infrastructure. Discharges from Caltrans' MS4s are regulated by the State Water Board. Caltrans participates in the SMRNIG; models developed by the group have estimated nutrient loading from Caltrans as illustrated in **Figure 3-6**.

3.2.2 Other NPDES Permitted Discharges

There are point source discharges within the watershed that are regulated under other statutes by the Regional Water Board and/or State Water Board. Examples of discharges and the associated regulatory mechanisms include:

- Publicly Owned Treatment Works: Individual NPDES permits issued by the Regional Water Board;
- Industrial sites: State Water Board Industrial Storm Water General Permit Order 2014-0057-DWQ;
- Construction sites (>1 acre): State Water Board Construction Storm Water General Permit Order No. 2012-0006-DWQ; and

- Pumped Groundwater (i.e., dewatering): Multiple Regional Water Board Permits (e.g., Order R9-2008-0002).
- Caltrans MS4 Permit: Order 2012-0011-DWQ as amended by Order WQ 2014-0006-EXEC, Order WQ 2014-0077-DWQ, an Order WQ 2015-0036-EXEC; NPDES NO. CAS000003 National Pollutant Discharge Elimination System (NPDES) Statewide Storm Water Permit Waste Discharge Requirements (WDRs) for State of California Department of Transportation.

Regulation of these sources is generally performed by the permitting agency (i.e., State Water Board, Regional Water Board); however, some are regulated by both the permitting authority and the Copermittees and the City of Menifee (e.g., industrial sites, construction sites, illicit discharges). Publicly Owned Treatment Works (POTWs) (i.e., publicly owned sewage treatment plants) may also be another potential source, however, POTWs are traditionally regulated through individual NPDES permits.

3.2.3 Other Point Sources

Copermittees and the City of Menifee have not identified other point source discharges within the watershed (e.g., privately owned MS4s). However, where there are privately owned systems that contribute flows, during dry or wet weather, into an agency's MS4, these discharges are regulated by the agency through various programs and ordinances (e.g., commercial or residential inspections programs). There is also potential for the sanitary sewer collections systems within the watershed to act as a point source discharge if there are sanitary sewer overflows. These systems are regulated under State Water Board Order No. 2006-0003-DWQ. Copermittees and the City of Menifee may also address these types of discharges through their IDDE and existing development programs where appropriate.

3.2.4 Non-Point Sources

There are non-point source discharges within the watershed that are regulated under other statutes by the Regional Water Board and/or State Water Board. Non-point sources (and their regulatory mechanism, where applicable) that may contribute to nutrient loads within the watershed include:

3.2.4.1 Onsite Wastewater Treatment Systems (OWTSs): Regional Water Board Conditional Waiver #1 (California Regional Water Quality Control Board, 2007) and State Water Board OWTS Policy (California State Water Resources Control Board, 2012c)

Due to the presence of OWTSs within the watershed, the Copermittees have identified OWTSs (i.e., septic systems) as a potential non-point source discharge that could contribute nutrient loading to receiving waters. Septic systems are widely distributed throughout the Copermittees' jurisdictions in the SMR WMA. Septic systems could impact Copermittees' MS4s, and are commonly found upstream of reaches identified as impacted by eutrophication impacts or nutrient loading. A total of 3,940 parcels within the Riverside County portion of the SMR WMA are permitted to use septic systems and comprise an area of approximately 35,689 acres (**Figure 3-7**). The extent and influence of septic systems in the San Diego portion of the SMR WMA is undetermined. Leaking or malfunctioning septic systems have the potential to contribute to dry weather nutrient loads through two mechanisms: 1) direct infiltration to the receiving water, and 2) infiltration to the MS4.

3.2.4.2 Agricultural Discharges

A commercial agricultural operation is defined as any agricultural business or trade activity, including farms, nurseries, and orchards, that produces crops with the intent to make a profit. Discharges from commercial agriculture have been shown to contribute significant nutrient loads to receiving waters within the watershed as shown in **Figure 3-6**. The Regional Water Board regulates commercial agricultural operations under these agricultural waste discharge requirements (WDRs) issued in 2016:

- Regional Water Board Order No. R9-2016-0004 General Waste Discharge Requirements for Discharges from Commercial Agricultural Operations for Dischargers that are Members of a Third-Party Group
- Regional Water Board Order No. R9-2016-0005 General Waste Discharge Requirements for Discharges from Commercial Agricultural Operations for Dischargers that are not Participating in a Third-Party Group

Agricultural operations enrolled under these orders are required to implement BMPs, perform monitoring, and report on implementation and results. Agricultural operations currently enrolled under the WDRs are illustrated in **Figure 3-8**.

The SMRNIG modeling efforts demonstrate that very little loading of TN and TP is discharged from commercial agriculture operations into the MS4s within the incorporated cities in the watershed (see **Table 3-8**). Conversely, multiple commercial agricultural operations are present in the unincorporated areas within the watershed and may contribute to TN and TP loading in MS4s, as shown in **Table 3-8**.

Strategies to address nutrient sources from commercial agricultural discharges are included in **Chapter 4**. When illicit dry weather discharges and wet weather runoff with potentially high levels of nutrients from these operations are encountered, the agencies will coordinate with the agricultural dischargers and the Regional Water Board to ensure that the facilities are aware of the agricultural WDRs, as applicable, and compliant with local water quality ordinances.

Some agricultural operations are not required to enroll under the general agricultural orders. These small growing operations on residential lots are not producing with the intent to make a profit. These operations may discharge to the MS4s and will be addressed primarily through the Permittees' IDDE programs.

All Permittees within the SMR watershed maintain adequate legal authority through their stormwater ordinances to require and enforce the implementation of control strategies to address illicit discharges of nutrients to their MS4s. Examples of BMPs to be implemented by various agencies are provided below. The list is a compilation of strategies from the agencies that may be applied to agricultural operations whether or not they are enrolled under the applicable Water Board Agricultural WDRs. The list is not meant to apply to a single agency, nor is it inclusive of all options at an agency's disposal.

Dry Weather

- Enhancement of the commercial / industrial / municipal inspection programs to focus on irrigation systems;

- Utilization of municipal personnel and contractors to monitor storm water outfalls for discharges of potential illicit connections and illicit discharges; and
- Enforce escalating legal authority established for all inventoried existing development, including residential and agricultural, to conserve water and eliminate dry weather flows.

Dry and Wet Weather

- Identification, investigation, and elimination of illicit discharges to the MS4;
- Require implementation of BMPs to address application, storage, and disposal of pesticides, herbicides, and fertilizers on commercial, industrial, agricultural (e.g., large commercial nurseries), residential, and municipal properties;
- Notify agricultural business license holders of requirement to enroll in the Regional Water Board Agricultural Order;
- Develop and implement enhanced outreach programs targeting nurseries;
- Develop and distribute informational brochures for nurseries and vineyards that focus on BMPs that reduce nutrients in runoff;
- Collaborate with watershed partners to develop consistent messaging to targeted audiences, such as commercial residents to conserve water and reduce dry weather flows; and
- Implement escalating enforcement responses to compel compliance with ordinances, permits, contracts, orders, and other requirements for ICID, development planning, construction management, industrial/commercial, municipal, and residential development (including residential equestrian and livestock activities).

3.2.4.3 Groundwater Seepage

Groundwater seepage is another potential non-point source of nutrients to MS4s and receiving waters within the watershed. Modeling performed by the SMRNIG has estimated loading from groundwater to receiving waters as illustrated in **Figure 3-6**.

3.2.4.4 Homeless Encampments

Copermittees also have information indicating the presence of homeless encampments within the watershed. While these encampments are likely non-point sources of human waste to receiving waters, the impacts of encampments on water quality have not been quantified.

3.2.4.5 Natural Sources

Environmental sources are most often non-point or diffuse in nature. These include sources of pollution that are naturally present in the environment. Copermittees have limited control over these sources. Examples of environmental sources of pollution present within the WMA include atmospheric deposition, leaf litter and debris, natural wildlife sources, natural erosion, and natural groundwater, all of which may be present in open space areas. Natural sources that can be anthropogenically influenced include groundwater quality altered by imported water supplies, aerial deposition of transportation and industrial pollutants, and erosion exacerbated by

hydromodification[10]. Contributions of nutrient loads from open space have been estimated through models developed by the SMRNIG and are shown in **Figure 3-6**.

[10] In contrast to other anthropogenically influenced natural sources, erosion caused by hydromodification is addressed under the Permit through the Land Development requirements in Provision E.3.

3.3 REVIEW OF AVAILABLE DATA

The Permit requires that the Copermittees provide the findings of sources of pollutants and/or stressors from the available data reviewed, including, but not limited to, the following:

- Findings from illicit discharge detection and elimination programs;
- Findings from outfall discharge monitoring, receiving water monitoring, and outfall discharge and receiving water assessments; and
- Other available, relevant, and appropriately collected data, information, or studies related to pollutant sources and/or stressors that contribute to the HPWQC.

3.3.1 Illicit Discharge Detection and Elimination (IDDE) Programs

Municipalities operate illicit discharge detection and elimination (IDDE) programs that involve conducting illegal connection/illicit discharge (IC/ID) investigations and inspections to comply with program requirements. A summary of IC/ID activities by agency is shown in **Table 3-7**. The IC/ID data was provided by the agencies with an assessment of the predominant sources most commonly associated with IC/IDs in their jurisdictions.

Table 3-7. Number of IC/ID Activities Conducted as Part of the IDDE Program

IC/ID Activities	FY 11-12	FY 12-13	FY 13-14	FY 14-15	FY 15-16	Predominant Source(s) Associated with Discharge(s)

ND = no data; N/A = not applicable

3.3.2 Findings from Major MS4 Discharge and Receiving Water Monitoring and Associated Assessments

The Permit requires the Copermittees to present the findings of potential pollutant sources from available MS4 outfall monitoring, receiving water monitoring, and MS4 outfall discharge and receiving water assessment data. A preliminary assessment of the receiving water conditions

(Permit Provision B.2.a.) and an assessment of impacts from MS4 discharges (Permit Provision B.2.b) were conducted as the first step in the process used to develop a list of priority water quality conditions. Detailed findings from these assessments can be found in **Section 2.4**. While the monitoring data identifies concentrations of pollutants, potential sources of nutrients to the MS4s have not been well-identified in the assessments. The best assessment of sources comes from the SMRNIG technical reports which are summarized in **Section 3.3.4**. Those reports identify residential land uses as the primary nutrient source for most jurisdictions, but several other sources, including commercial, industrial, nurseries, horse ranches and other agriculture could contribute loads depending on their presence within jurisdictions.

3.3.3 Other Data or Studies Related to Pollutant Sources

The Permit requires the Copermittees to consider other available, relevant, and appropriately collected data, information, or studies related to pollutant sources and/or stressors that contribute to the highest priority water quality condition. Available other data and studies that were reviewed as part of the development of the WQIP are summarized in **Appendix 3A**.

Study results from the SMRNIG efforts are further discussed in **Section 3.3.4**. The three non-SMRNIG related studies that are relevant to nutrient loading in the watershed are discussed below.

3.3.3.1 Agricultural, Federal, Tribal, and State Input Special Study, 2014 Annual Progress Report

The Agricultural, Federal, Tribal, and State Input Special Study (Weston Solutions, 2014) was conducted in order to determine the type, quantity, and estimated loading of pollutants in runoff from discrete areas of agricultural, federal, tribal, and state lands, as well as state highway source areas.

Based upon the two years of monitoring data, the pollutant concentrations were characterized for the target source inputs. At Tribal Site 1, constituents measured above water quality criteria during at least one monitoring storm included bacteria (*Enterococcus*, *E. coli*, and fecal coliform), total phosphorus, surfactants (MBAS), turbidity, and some metals (total iron, total manganese, dissolved copper, and dissolved zinc). At Agriculture Site 8, constituents measured above water quality criteria during at least one monitored storm included bacteria (*Enterococcus*, *E. coli*, and fecal coliform), turbidity, total phosphorus, and some metals (total iron, total and dissolved manganese, and total chromium). At Federal Site 1, concentrations of turbidity, total phosphorus, and *Enterococcus* were greater than applicable water quality criteria during the monitoring storm event. Although limited in scope, this study demonstrates that agriculture, tribal, and other federal lands contribute nutrient loads to the watershed. These findings, are further supported by the modeling performed in the watershed as part of the SMRNIG, discussed in **Section 3.3.4**.

3.3.3.2 2011 Long-Term Effectiveness Assessment, San Diego Stormwater Copermittees Urban Runoff Management Programs, Final Report

As part of the Long-Term Effectiveness Assessment (San Diego Stormwater Copermittees, 2011) (LTEA) required for permit renewal in 2011, the Copermittees examined the various sources of pollutants required to be regulated by the Permit in an effort to determine which sources had the most potential to contribute loads of various pollutants of interest to the MS4 (source loading potential). The analysis looked at several pollutants/pollutant groups including nutrients and qualitatively assigned a source loading potential of none, unknown, unlikely, or likely to each of

36 source areas or activities. Although not specific to the SMR WMA, the findings align well with and support the source analysis in this Plan. The analysis concludes that the following sources have a likely potential to contribute nutrients to MS4 discharges and/or receiving waters: residential areas and activities; roads, streets, highways, and parking facilities; parks and recreational facilities; botanical or zoological gardens and nurseries/greenhouses; mobile landscaping; and animal kennels.

3.3.3.3 Geotracker Site 1120 (Camp Pendleton Marine Corps Base Site – 1120 Stuart Mesa)

Stuart Mesa West and East Agricultural Fields is an area of approximately 376 acres on the Camp Pendleton Marine Corps Base. The area is bordered on the northeast by Stuart Mesa Road, on the southwest by the Pacific Ocean, on the south and southeast by the SMR and the SMR Estuary, and by the Marine Corps Tactical Systems Support Facility (MCTSSA) on the west and northwest. The agricultural fields were used for growing tomatoes and strawberries and other agricultural uses for at least 70 years.

In March 2011, the Stuart Mesa Agricultural Fields property lease was terminated, and the fields have been fallow. However, runoff from the fallow agricultural fields has the potential to impact the SMR Estuary, as noted in a letter from the Regional Water Board to the Marine Corps Base (California Regional Water Quality Control Board, San Diego Region, 2017a). For example, unmaintained earthen berms can be erosive and contribute to nutrient loading. Since termination of the lease, the west and east agricultural fields have undergone remediation for identified areas with contaminants of potential concern. Data obtained from the Geotracker website was reviewed and it did not appear that nutrients were included in the monitoring program. However, modeling performed as part of the SMRNIG studies does indicate the site as a potential source of nutrients in the Lower SMR Subwatershed. Estimated loading of nutrients for the site is illustrated in **Figure 3-6**.

3.3.4 Findings from TMDL Alternative Technical Reports

Based on the watershed modeling performed for the SMRNIG to support development of the TMDL Alternative for the SMR Estuary (Sutula, et al., 2016), several land use categories have been identified as having potential to contribute loads of total nitrogen and total phosphorus to the SMR WMA.

- Total Nitrogen - The model identifies irrigated agriculture, orchards, vineyards and nurseries, open scrublands and grasslands, and residential land uses as the largest contributors of total nitrogen load to the Santa Margarita River.
- Total Phosphorus - The model identifies total phosphorus loading as being contributed by roads, orchards, vineyards and nurseries, open scrublands and grasslands, and residential land uses.

Figure 3-6 shows the major pathways and sources identified in the Model Application Report and subsequent technical memorandums for Total Nitrogen and Total Phosphorus.

As shown in the figure, sources of nutrients reach the SMR Estuary through several pathways. Discharges from agricultural areas, Caltrans, Camp Pendleton, and other federal lands, including tribal lands, can discharge directly to receiving waters and the SMR Estuary. Some of these sources also can enter the MS4 and contribute to loadings from the MS4, along with commercial,

industrial, and open space sources. Many of the land uses that the model identifies as contributing to nutrient loading in the SMR Estuary can be found adjacent to the reaches the Copermittees have identified as impacted by eutrophic conditions and/or nutrient loading. **Table 3-8** shows the relative contribution of each of these sources to the MS4. RCFCWCD and the City of Menifee were not included in the modeling efforts and do not have loads assigned. If determined to be necessary by the SMRNIG, these agencies may be added during future iterations of the model as part of the adaptive management process to provide a more complete understanding of nutrient loading from all agencies in the watershed.

Table 3-8. Dry Weather Sources of Total Nitrogen (TN) and Total Phosphorus (TP) within Each Jurisdiction based on the Tetra Tech Loading Analysis Memo Dated May 15, 2017 Percentage of Total Loading from MS4 Discharges Attributable to Each Source[1, 2]

1. Under the Regional Water Board Designation Letter dated October 26, 2015 Menifee is required to participate in the development and implementation of the SMR WQIP and the implementation of any applicable TMDL. However, no specific load allocations have been assigned to Menifee. Menifee was not included in the modeling efforts. Because Menifee only has a small jurisdictional area in the WMA (less than 2 square miles), Menifee will participate in the overall load reduction by implementing its WQIP and LIP strategies.

The findings of the SMR technical reports demonstrate that residential sources are the most significant source of nutrients to the storm drain system for most jurisdictions with some portion of the loading coming from all other sources. Only in San Diego County orchards, vineyards and nurseries are the most significant, with residential sources secondary. As part of the WQIP development, San Diego County conducted additional modeling to separate contributions of

nurseries from orchards and vineyards in the Rainbow Creek Subwatershed and determined that nurseries are the largest source of nutrients to the storm drain system. (Tetra Tech, 2017)

3.4 DATA ADEQUACY

While the available data is considered accurate, appropriately collected, and analyzed for potential sources contributing to eutrophication impacts and nutrient loading, information to determine if the potential sources are contributing to problems in the receiving waters is relatively sparse. To provide this linkage, source information has been used in combination with efforts to model nutrient loads to provide adequate rationale for identifying and prioritizing sources and/or stressors.

3.5 CONCLUSIONS FROM SOURCE INFORMATION

Based on the available source information as discussed above, combined with information generated through local studies for eutrophication in the watershed, and best professional judgement, each agency was able to prioritize the top three types of sources within their jurisdiction that may be contributing nutrients to their storm drain system. The prioritization is intended to provide guidance to agencies in selecting appropriate strategies to address sources of nutrients contributing to the storm drain system within their respective jurisdictions. These relative source rankings are summarized in **Table 3-9**.

Table 3-9. Prioritized Sources by Agency Based on Available Information

Sources	County of San Diego[1]	County of Riverside[2]	City of Menifee[3]	City of Murrieta[4]	City of Temecula[5]	City of Wildomar[6]	RCFCWCD[7]
Residential	2	1	1	1	1	1	1
Commercial	-	-	3	2	2	3	2
Industrial	-	-	-	-	3	-	-
Parks and Recreation	-	-	-	-	-	-	-
Orchards, Vineyards and Nurseries	1	2	-	-3	-	-	3
Horse Ranches	-	3	2	-	-	2	-
Other Agriculture	3	-	-	-	-	-	-

1. The source prioritization for the County of San Diego is primarily based on modeling results produced by the SMRNIG, source information related to the TMDL for Rainbow Creek, and land use information for their areas of the watershed.
2. The source prioritization for the County of Riverside is primarily based on modeling results produced by the SMRNIG, land use information, and inventory information.
3. The source prioritization for the City of Menifee is primarily based on land use information and modeling results produced by the SMRNIG. Although no loading estimates were provided for the City of Menifee, the model does demonstrate the general significance of loading from residential areas.
4. The source prioritization for the City of Murrieta is primarily based on the City's knowledge of facilities in this portion of the City, land use information, and inventory information.
5. The source prioritization for the City of Temecula is primarily based on modeling results produced by the SMRNIG, land use information, and inventory information.
6. The source prioritization for the City of Wildomar is primarily based on modeling results produced by the SMRNIG, land use information, and inventory information.
7. The source prioritization for the RCFCWCD is primarily based on available IC/ID information, including the predominant sources of illicit discharges as identified in **Table 3-7**. Because other agencies discharge to RCFCWCD facilities, the source prioritization results for the other agencies in the Upper and Middle SMR Subwatersheds were also considered.

4 Water Quality Improvement Goals, Strategies, and Schedules

Provision B.3 of the Permit, "Water Quality Improvement Goals, Strategies and Schedules," describes the requirements to develop specific water quality improvement goals and strategies to address the PWQCs identified as per Permit Provision B.2 (and described in **Chapter 2**) for the SMR WMA. These goals and strategies must effectively prohibit non-stormwater discharges to the MS4, reduce pollutants in stormwater discharges from the MS4 to the maximum extent practicable, and protect water quality in receiving waters. In practical terms, the strategies will address the key sources of nutrients contributing to the MS4 within each jurisdiction and/or change the physical factors in the receiving water to reduce the growth of algae or improve dissolved oxygen conditions (e.g. restoration of stream channels) and the goals will be used to assess improvements in water quality and effectiveness of the strategies.

Chapter 4 defines the goals, along with strategies and schedules for achieving those goals. The goals include interim and final numeric (i.e., quantifiable) goals for the HPWQC as described in **Chapter 2**, and summarized in **Table 4-1**.

Table 4-1. Highest Priority Water Quality Condition

Beneficial Use Category	Highest Priority Water Quality Condition	Temporal Extent	Geographic Extent
Aquatic Life: Eutrophication	Eutrophication impacts (elevated algal biomass)	Dry	SMR Estuary [1], Warm Springs, Redhawk Channel [2]
	Nutrient loading to waterbodies with an adopted TMDL or listed as impaired	Dry	All Middle and Lower SMR subareas, except Fallbrook Creek and Sandia Creek[1]
		Wet	Rainbow Creek

1. MS4 discharges within the following subareas may reach the SMR Estuary during dry weather and contribute to the Eutrophication PWQC in the SMR Estuary: Upper Murrieta Creek and Tributaries, Warm Springs, Santa Gertrudis, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Lower Santa Margarita River, Rainbow Creek and De Luz Creek.
2. Other areas may be added as result of TMDL Alternative development during adaptive management process.

As shown in the table, the HPWQC consists of in-stream eutrophication impacts in the SMR Estuary, Warm Springs and Redhawk Channel. As shown in **Figure 2-8**, increased nutrient loading to the waterbody can cause eutrophication, but other factors, such as shading, temperature, flow, and substrate influence whether increased nutrient loading causes eutrophication. As a result, while nutrient loading occurs throughout the watershed, evidence of eutrophication is not present in all reaches. The other part of the HPWQC to be addressed is the nutrient loading to the waterbodies where eutrophication is occurring. Because the SMR Estuary is at the base of the watershed, all MS4 discharges that might reach the SMR Estuary during dry weather are addressed by the goals and strategies in this chapter. Additionally, nutrient loadings during wet weather to Rainbow Creek are a HPWQC.

Through the implementation of strategies developed to address potential sources of nutrients and an iterative, adaptive management approach, it is anticipated that the numeric goals will be

achieved and the water quality will be improved. Each agency will implement a JRMP or LIP that contains strategies to meet the requirements of Permit Provisions E.2 through E.7. The JRMPs/LIP contain all BMPs that will be implemented across programs as required by Provision E of the Permit. Additionally, each agency will implement additional strategies to address anthropogenic sources of nutrients that contribute pollutants via the MS4 (as described in Permit Provisions B.3.b(1)(a)(i)-(vi)). Jurisdictional strategies will address sources of nutrients within the agency's jurisdiction. Optional strategies have also been developed for each jurisdiction, but will be implemented only if certain triggers are met (e.g., where interim goals are not met). WMA strategies have been developed that are also optional (i.e., must be triggered), but are regional or multi-jurisdictional in nature.

4.1 GOALS AND SCHEDULES TO ADDRESS EUTROPHICATION AND NUTRIENT LOADING

The purpose of establishing goals is to support WQIP implementation and measure reasonable progress towards addressing the HPWQC. The Permit requires that goals be reflective of criteria or indicators to measure incremental progress towards addressing the HPWQC over the course of implementation of the WQIP. Goals for the HPWQC, and the process to achieve them, are fundamental to the WQIP. Permit Provision B.3 outlines requirements for goals, which include numeric targets for interim and final goals for the HPWQC:

- Interim Goals must be based on measureable criteria or indicators capable of demonstrating reasonable incremental progress toward achieving the final numeric goals. Each final goal must have one or more interim goal, with at least one interim numeric goal expressed as a reasonable increment toward achievement of the final numeric goal, to be accomplished during each 5-year period between the acceptance of the WQIP and the achievement of final numeric goals.
- Final Goals must be based on measureable criteria or indicators capable of demonstrating one or more of the following: (i) discharges from Copermittees' MS4s will not cause or contribute to exceedances of water quality standards in receiving waters; (ii) the conditions in receiving waters and associated habitat are protected from MS4 discharges; or (iii) beneficial uses of receiving waters are protected from MS4 discharges and will be supported.

4.1.1 Geographic Extent of Eutrophication HPWQC

The HPWQC for eutrophication was identified for three subareas in the watershed: SMR Estuary, Warm Springs and the Redhawk Channel portion of the Temecula Creek and Redhawk Channel subarea. Warm Springs and Redhawk Channel are located in the Middle SMR Subwatershed, and evidence of eutrophication was limited to one location in each of these creeks with limited sampling data (see **Chapter 2**). The 192-acre SMR Estuary is located at the base of the watershed in the southwestern portion of Marine Corps Base Camp Pendleton. The SMR Estuary receives drainage from both the Middle and Lower SMR Subwatersheds. In contrast to Warm Springs and the Redhawk Channel portion of the Temecula Creek and Redhawk Channel subarea, the SMR Estuary has been extensively studied and monitored. **Figure 4-1** shows the SMR Estuary and its location within the SMR WMA.

Eutrophication can be caused by both physical factors (flow conditions, waterbody shading, substrate, etc.) and discharges of nutrients. While the geographic extent of the evidence of eutrophication is limited to three subareas in the SMR WMA, dry weather discharges of nutrients from MS4 outfalls to all areas of the watershed have the potential to contribute to the eutrophication in the SMR Estuary. Consistent with the TMDL Alternative, dry weather is defined to include dry conditions (where there is less than 0.1 inch of rainfall within the previous 72 hours) year-round, encompassing both the dry and wet seasons[11]. The subareas with dry weather MS4 discharges that could potentially reach the SMR Estuary are: Upper Murrieta Creek and Tributaries, Warm Springs, Murrieta and Long Canyon Creek, Santa Gertrudis Creek, Temecula Creek and Redhawk Channel, Upper Santa Margarita River, Lower Santa Margarita River, Rainbow Creek, and De Luz Creek. As a result, all subareas where dry weather flows from the MS4 may occur and include nutrient loading are included in the geographic extent of the HPWQC. Upper SMR Subwatershed does not contribute flows downstream of Diamond Valley Lake, Lake Skinner, or Vail Lake during dry weather conditions.

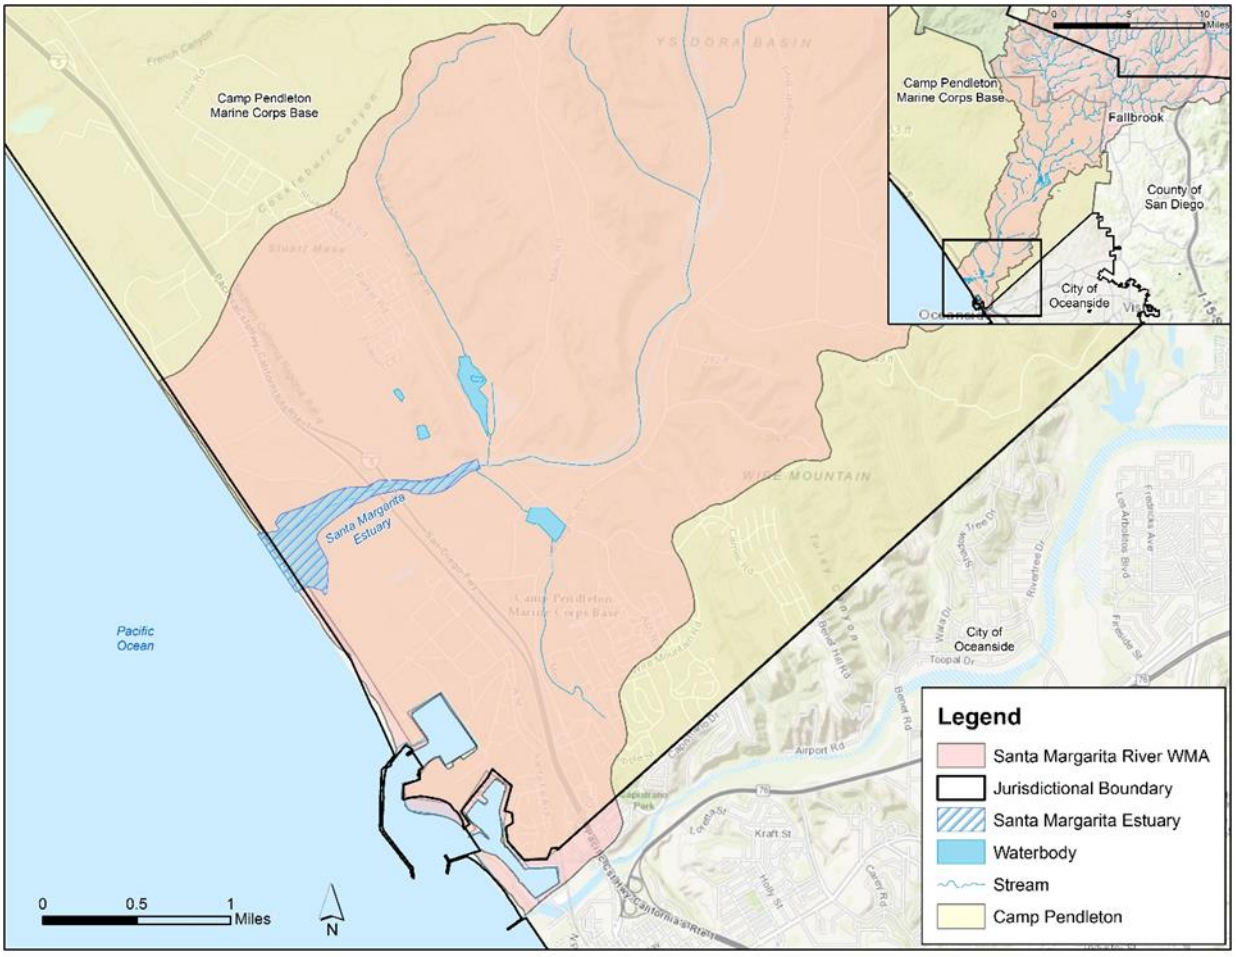

Figure 4-1. Santa Margarita River Estuary Location in the Santa Margarita River WMA

[11] Defined in Permit Provision D.1.c.

In the Middle SMR Subwatershed, goals and schedules that will address both localized eutrophication in Warm Springs and Redhawk Channel and nutrient loadings to the downstream SMR Estuary have been identified. In the Lower SMR Subwatershed, goals and schedules have been developed to address the eutrophic conditions in the SMR Estuary as well as the nutrient loading in the Rainbow Creek subarea.

All of the goals and schedules have been structured to achieve the anticipated targets for the TMDL Alternative for the Estuary, as described in more detail in **Section 4.1.2**. Differences among goals and schedules were identified to match jurisdiction and subwatershed-specific strategies and schedules. This approach provides the framework for a more accurate assessment of progress toward achieving goals within each subwatershed. Ultimately, protection of the receiving waters is the desired outcome.

4.1.2 TMDL Alternative Background

The Copermittees and the City of Menifee have developed goals to address the TMDL Alternative for the SMR Estuary that is currently under development. However, the TMDL Alternative for the SMR Estuary is not yet final, and targets and allocations are still being established. The Copermittees and the City of Menifee have utilized the available TMDL Alternative information in developing their respective goals. This section provides a discussion of the available information and how it was appropriately considered to help inform the selection of the goals.

The Basin Plan WQOs can be described as narrative WQOs with numeric guidance for interpretation of the narrative language. These numeric interpretations have been utilized historically for 303(d) listing decisions, TMDLs, and permit conditions. However, the objectives were established in the 1970s and regulatory and scientific approaches to evaluating biostimulatory objectives have since evolved. It is now recognized that due to site-specific factors (such as hydrology, shading, temperature), total nitrogen and total phosphorus concentrations and loads that can contribute to primary producer overproduction at levels that impact beneficial uses, vary greatly among streams and estuaries.

Current numeric interpretations of the narrative Basin Plan nitrogen and phosphorus WQOs do not consider site-specific factors. An alternative regulatory approach advocated by Regional Water Board staff and USEPA Region 9, is currently under development as part of the Statewide Biostimulatory and Bio-objectives Amendment (Biostimulatory Substances Amendment) being developed by the State Water Board. The State Water Board is proposing to adopt a statewide WQO for biostimulatory substances along with a program of implementation as an amendment to the Water Quality Control Plan for Inland Surface Water, Enclosed Bays and Estuaries of California (ISWEBE Plan). The Biostimulatory Substances Amendment will likely include a statewide narrative objective (with numeric guidance for interpretation), and various regulatory control options for point and non-point sources. This framework will be used to develop scientifically-sound water quality goals for biostimulatory substances that are protective of beneficial uses.

Although the State Water Board's work is still in process, the framework described above is being utilized for the TMDL Alternative development. As a result, TMDL Alternative targets for the SMR Estuary will not be set equal to the numeric interpretation of the Basin Plan objectives (i.e., 1.0 mg/L for total nitrogen and 0.1 mg/L for total phosphorus) that were used as the basis for the

303(d) listings. Instead, the TMDL Alternative for the SMR Estuary is expected to include some combination of dissolved oxygen, algal biomass, and benthic macroinvertebrate targets.

As discussed in more detail in **Section 5.2**, two models have been developed to support the TMDL Alternative development: the Estuary model and Watershed Loading model. The Estuary model was used to evaluate a range of possible water quality targets for the SMR Estuary that would align with the Biostimulatory Substances Amendment framework. The Watershed Loading model was used to estimate the amount of total nitrogen and total phosphorus loading from the watershed. Based on the analysis presented in the Model Application Report, the SMRNIG discussed potential targets for the SMR Estuary.

As of February 2017, the following targets were being considered for the TMDL Alternative for the SMR Estuary (County of San Diego, 2017a):

- A primary algal biomass target of 57 grams (dry-weight) per cubic meter [g d-wt/m^2];
- A secondary numeric target for algal biomass of 70 g d-wt/m^2;
- A dissolved oxygen target of not less than 5.0 mg/L; and
- If monitoring data confirm that the SMR Estuary is meeting the primary target of algal biomass of 57 g d-wt/m^2, this result indicates that the beneficial uses are protected. If monitoring data confirm that the SMR Estuary is meeting an algal biomass between 57 and 70 g d-wt/m^2, the Sediment Quality Objective (SQO) tool (http://www.sccwrp.org/Data/DataTools/SedimentQualityAssessment.aspx) for benthic community structure will be used to assess whether beneficial uses are protected. If the dissolved oxygen target is being met and the SQO tool indicates beneficial uses are protected, the SMR Estuary targets are being met regardless of the algal biomass concentrations.

In the TMDL Alternative analysis, year-round dry weather discharges were determined to be primarily responsible for identified impairments in the SMR Estuary. Wet weather loadings were determined to be primarily flushed to the Pacific Ocean, and modeled reductions in wet weather loads did not have an appreciable impact on improving SMR Estuary conditions. As a result, wet weather load reductions are not required by the TMDL Alternative for the SMR Estuary.[12]

The Estuary model was used to evaluate the load reductions in total nitrogen and total phosphorus needed to meet the targets based on the 2008 to 2009 Water Year simulated in the model. Based on the model results, the SMRNIG has developed a proposal for allocations for the TMDL Alternative for the SMR Estuary (County of San Diego, 2017b). The proposed allocations apply a 76% reduction equally to all controllable discharges within the SMR WMA, which are defined for the purposes of the TMDL Alternative as discharges covered by WDRs or NPDES permits. Other discharges are not subject to load reduction goals, as they are either naturally occurring (e.g., open space) or releases necessary to protect other beneficial uses (e.g., Comprehensive Water Rights Management Agreement flows). While the Regional Water Board has provided preliminary

[12] If wet weather loadings are identified in the future as a source that is required to be addressed by the TMDL Alternative for the SMR Estuary or TMDLs for the other portions of the SMR WMA, the Water Quality Improvement Plan goals and strategies will be updated as required through the adaptive management process.

positive feedback on the allocation proposal, the TMDL Alternative for the SMR Estuary is still under development and the proposal may be modified before it becomes final.

Compliance with requirements in applicable Orders is expected to attain and maintain the allowable loadings from controllable discharges in the TMDL Alternative for the SMR Estuary. Non-storm water discharges are generally effectively prohibited by the existing MS4 Permit requirements (Order No. R9-2013-0001, as amended by Order No. R9-2015-0001 and Order No. R9-2015-0100) and the agricultural orders (Orders No. R9-2016-0004 and R9-2016-0005). However, several non-controllable discharges exist in the watershed that may cause the SMR Estuary to exceed the proposed receiving water targets. Should a demonstration be made that all controllable discharges have been addressed and are meeting allocations and the SMR Estuary continues to exceed receiving water targets, modifications to the targets may be considered to reflect the impact of natural sources. Under such conditions, the TMDL Alternative for the SMR Estuary will not require additional load reductions from the controllable discharges to meet the receiving water targets in the SMR Estuary.

4.1.3 Numeric Goals and Schedules for the SMR Watershed

The Copermittees used the geographic extent of the eutrophication and nutrient loading, in combination with scientific studies and modeling performed as part of the SMR Estuary TMDL Alternative and the Rainbow Creek Nutrient TMDL, to develop numeric goals for the watershed. The goals are presented in the following sections.

4.1.3.1 Goals and Schedules to Address Eutrophication and Nutrient Loading in the Middle SMR Subwatershed[13]

The Middle SMR Subwatershed consists of six subareas (**Figure 2-3**). Copermittees have MS4 outfalls that discharge to portions of five of the six subareas. The evaluation of MS4 outfall data indicates that total nitrogen and total phosphorus discharges from the MS4 during dry conditions, which may occur year-round, have the potential to contribute nutrient loading to the SMR Estuary, Warm Springs, and Redhawk Channel. As a result, the geographic extent of the HPWQC in the Middle SMR Subwatershed include the portions of the Upper Murrieta Creek and tributaries, Warm Springs, Santa Gertrudis Creek, Murrieta Creek and Long Canyon Creek, and Temecula Creek and Redhawk Channel subareas to which MS4 outfalls discharge during dry weather. There are no MS4 outfalls that discharge to other subareas in the Middle SMR Subwatershed.

Interim and final goals and schedules for the Middle SMR Subwatershed are presented in **Table 4-2**. A multi-tiered approach to setting goals was used. The compliance pathways for agencies to meet the WQIP goals are also shown in the table. The compliance pathways are based on six different metrics. Each Copermittee in the Middle SMR Subwatershed will have the option of demonstrating compliance through one of the six pathways. As such, the pathways are presented sequentially, separated by "OR" to indicate that any one of the six pathways may be followed for compliance. Each pathway includes interim goals, with at least one goal per Permit term, to demonstrate progress toward achieving the final goals. The first two pathways support a watershed-based approach as they focus on achievement of goals in receiving waters to demonstrate progress toward meeting load reductions and targets based on the TMDL Alternative.

[13] Cities of Menifee, Murrieta, Temecula, and Wildomar, Riverside County Flood Control and Water Conservation District, and Riverside County.

The second two pathways include MS4 discharge goals, to demonstrate progress and provide jurisdictional accountability toward meeting the TMDL Alternative-based load reductions and targets. The last two pathways account for natural loading, and provide a BMP-based option through WQIP implementation. The following six pathways are presented in **Table 4-2**:

Pathway 1. *Demonstration that the discharger is attaining the load reduction goal of 76% in the Middle SMR Subwatershed in receiving waters.*

Pathway 2. *Demonstration that the Santa Margarita River Estuary targets (based on the proposed TMDL Alternative) have been attained.*

Pathway 3. *Demonstration that non-stormwater flows that are within agency control have been reduced to meet load reductions.*

Pathway 4. *Demonstration that discharger is meeting required load reductions as described in the TMDL Alternative for the SMR Estuary.*

Pathway 5. *Demonstration that exceedances of targets are due to sources outside of agency control.*

Pathway 6. *Demonstration that management actions to attain load or flow reductions are being implemented through mechanisms defined in the accepted Water Quality Improvement Plan.*

The final goals were identified based on the proposed wasteload allocations and required load reductions proposed for the TMDL Alternative for the SMR Estuary. The proposed wasteload allocations used to establish goals are annual load reductions in dry weather discharges. As discussed above, dry weather discharges were determined in the TMDL analysis to be primarily responsible for identified impairments in the SMR Estuary. As such, the Middle SMR Subwatershed agency goals are applicable under dry conditions year-round (including both summer dry and winter dry conditions). Weather is considered dry if the preceding 72 hours has been without measurable precipitation (>0.1").

The interim goals were established conservatively, to reflect the anticipated reductions that can be achieved through each step of strategy implementation. The strategy implementation process is described in **Section 4.2**. The final goals and timeframe for achieving the goals is based on the implementation schedule anticipated for the final terms of the TMDL Alternative for the SMR Estuary.[14]

[14] The final goals and schedules are preliminary and will be updated through the adaptive management process when the TMDL Alternative becomes effective.

Table 4-2. Interim and Final Numeric Goals and Schedules, HPWQC – Eutrophication Impacts and Nutrient Loading, Middle Santa Margarita River Subwatershed Agencies (County of San Diego, 2017a)

Pathway	Interim Goal (2023)	Interim Goal (2028)	Interim Goal (2033)	Final Goal (2038) [6]	Metric

The Copermittees and the City of Menifee assess progress towards goals, implement the JRMP, enhanced JRMP strategies, optional jurisdictional strategies, or optional WMA strategies, as triggered through an iterative approach as described in the accepted Water Quality Improvement Plan.	Implementation of JRMP, enhanced JRMP strategies, optional jurisdictional strategies, or optional WMA strategies, as triggered through an iterative, adaptive management approach.

Notes:

1. Load reductions at the base of the Middle SMR Subwatershed will be measured against the baseline loads for Riverside County. Source: Tetra Tech. SMR Estuary MS4 Nutrient Loads for WY 2008. Memorandum to Jo Ann Weber, Kyle Cook, Kyle Gallup, and Stuart McKibbin, January 6, 2017. Baseline loads are 60,796 lb/yr for Total Nitrogen and 6,004 lb/yr for Total Phosphorus.
2. Dry weather conditions are defined as those that occur on non-storm days, with storm days being defined as all days with measured precipitation greater than 0.1 inch and the 72 hours following the measured precipitation, and include both summer and winter dry periods.
3. Within agency control means, consistent with the scope of the Permit, that conditions are within the regulatory authority of the Copermittee or the City of Menifee and can feasibly be addressed or treated at the point of entry, within, or at the outlets from the MS4. This requires the availability of feasible options for treating the condition. Flows/conditions determined to be uncontrollable would not be included in the calculations related to this goal.
4. Load reductions for the Riverside County Copermittees will be measured based on the baseline loads presented in the Tetra Tech memorandum: 9,933 lb/yr for Total Nitrogen and 990 lb/yr for Total Phosphorus. Jurisdictional load reductions for the jurisdictions provided in the Tetra Tech memo are shown in the table.
5. As described in Section 1, Menifee is participating in the development and implementation of this WQIP as required by the Regional Water Board Designation Letter dated October 26, 2015. Based on Menifee's land area in the Santa Margarita watershed, for the purpose of WQIP development and implementation, Menifee is determined by the San Diego Water Board to be a less than significant contributor of nitrogen, phosphorus and other pollutants within the Santa Margarita River Watershed Management Area. There are currently no numeric nutrient load goals for Menifee since no nutrient load values for the small portion of Menifee within the Santa Margarita watershed were included in the Tetra Tech study or any other currently published study, and any nutrient loading from within the City of Menifee to the Santa Margarita River Watershed is considered to be less than significant. Until the Santa Margarita Estuary TMDL stakeholders and the San Diego Water Board determine the final load allocation regarding Menifee, if such an allocation is needed, Menifee will implement appropriate LIP strategies to address the HPWQC in the WMA and meet the WQIP goals and schedules. Furthermore, while Menifee has limited MS4 conveyance structures in the SMR WMA, there are currently no MS4 outfalls located within the portion of Menifee in the Santa Margarita watershed. Therefore, achievement of goals will be demonstrated through pathways other than pathway 4.
6. The final goals and schedules are preliminary and will be updated through the adaptive management process when the TMDL Alternative becomes effective.

4.1.3.2 Goals and Schedules to Address Eutrophication Impacts and Nutrient Loading in the Lower SMR Subwatershed[15]

The first set of goals and strategies developed for the Lower SMR Subwatershed relate to the Estuary. Studies conducted to support development of the TMDL Alternative for the SMR Estuary indicate that eutrophic conditions are caused by excessive nutrient loading, which leads to excessive growth and decomposition of algae, and low dissolved oxygen conditions. Reducing dry weather flows from the San Diego County stormwater outfalls will ultimately reduce the nutrient loading that leads to the eutrophic condition in the SMR Estuary. Numeric goals addressing this HPWQC have been established to measure and demonstrate progress toward eliminating dry weather flows. The goals take two forms, though there are multiple compliance pathways to accomplish these goals. These goals are presented in **Table 4-3**.

Efforts to mitigate dry weather flows and consideration of small-scale structural controls (as needed) will begin during the next MS4 Permit term. The final compliance goal, scheduled for FY 2038, is zero persistent discharges from the County of San Diego's MS4 outfalls to receiving waters or a 100% reduction in anthropogenic dry weather flow volume. Compliance pathways for these goals will be demonstrated through the dry weather MS4 outfall field screening program, or the TMDL Alternative (final terms expected in 2018) targets for the SMR Estuary.

[15] The County of San Diego is the only Copermittee that has Major Outfalls in the Lower SMR Subwatershed.

Table 4-3. Interim and Final Numeric Goals and Schedules for HPWQC – Eutrophication in the Santa Margarita River Estuary, Lower SMR Subwatershed – San Diego County

	Assessment Period					
Goal[1]	**Baseline**	**FY2018-FY2023**	**1st Permit Term (FY2023)**	**2nd Permit Term (FY2028)**	**3rd Permit Term (FY2033)**	**4th Permit Term (FY 2038)**
Effectively eliminate anthropogenic dry weather discharges from MS4 outfalls to the receiving water	To be established during FY16–17 using dry weather[2] flow measurements	Complete turf replacement in Rainbow Park.	Reduce the baseline aggregate flow volume by 25%.	Reduce the baseline aggregate flow volume by 50%.	Reduce the baseline aggregate flow volume by 75%.	Reduce the baseline aggregate flow volume by 100%.
Comply with TMDL Alternative	**OR**					
	Demonstrate that the Santa Margarita River Estuary targets have been attained.[3]					
	OR					
	Demonstrate that the discharger is attaining the nutrient load reduction goal of 76%.					
	OR					
	Demonstrate that the discharger is attaining the load allocations defined in the TMDL Alternative for the SMR Estuary.					
	OR					
	Demonstrate that exceedances of the targets are due to non-controllable sources.					
	OR					
	Demonstrate that management actions to attain allocations are being implemented through mechanisms defined in each applicable Order.[4]					

Notes:

1. These goals are placeholders and may be updated on the basis of the final implementation requirements for the Santa Margarita River Estuary TMDL Alternative.
2. Dry weather conditions are defined as those that occur on non-storm days, with storm days being defined as all days with measured precipitation greater than 0.1 inch and the 72 hours following the measured precipitation, and include both summer and winter dry periods.
3. Primary and secondary numeric targets for algal biomass are proposed. If monitoring data confirm that the SMR Estuary is meeting the primary target of algal biomass of 57 g d-wt/m2, this result indicates that the beneficial uses are protected. If monitoring data confirm that the SMR Estuary is meeting an algal biomass between 57 and 70 g d-wt/m2, the Sediment Quality Objective (SQO) tool for benthic community structure will be used to assess whether beneficial uses are protected. The watershed load reduction goal to meet the numeric targets is 76%.
4. Mechanisms for implementing management actions include, but are not limited to, Phase I MS4 Water Quality Improvement Plans, Agricultural Discharger Water Quality Restoration Program Plans, Phase II MS4 permit program elements, and Caltrans compliance units, cooperative implementation grants and cooperative implementation agreements.

4.1.3.3 Goals and Schedules to Address HPWQC - Nutrients in Rainbow Creek

Nutrients (including nitrate, nitrogen, and phosphorus) in Rainbow Creek are identified as a HPWQC in the Lower SMR Subwatershed and goals and schedules have been developed to address that condition as well. The Rainbow Creek Nutrient TMDL (Water Quality Control Plan for the San Diego Basin (Basin Plan) Amendment: Resolution No. R9-2005-0036) was adopted in 2006 to address water quality impairments in Rainbow Creek (San Diego RWQCB, 2006). In 2013, the Rainbow Creek Nutrient TMDL was incorporated into Attachment E.3 of the Permit.

4.1.3.3.1 Geographic Extent of HPWQC-Nutrients in Rainbow Creek

The geographic extent of the HPWQC-Nutrients in Rainbow Creek is the area that drains into stormwater outfalls connected to Rainbow Creek within San Diego County. The Rainbow Creek drainage area encompasses 7,085 acres and approximately 65 percent of the area is undeveloped (Regional Water Board, 2006). The Clean Water Act Section 303(d) list of water quality impaired segments (303(d) list) identifies impairments as a result of excessive nutrient concentrations for an approximately 5-mile stretch of the creek **(Figure 4-2**) (Regional Water Board, 2015).

Rainbow Creek supports a number of beneficial uses. The most sensitive beneficial uses are those designated for protection of aquatic life, as described in the Basin Plan (Regional Water Board, 1994) definition of the warm freshwater habitat (WARM) and cold freshwater habitat (COLD) beneficial uses.

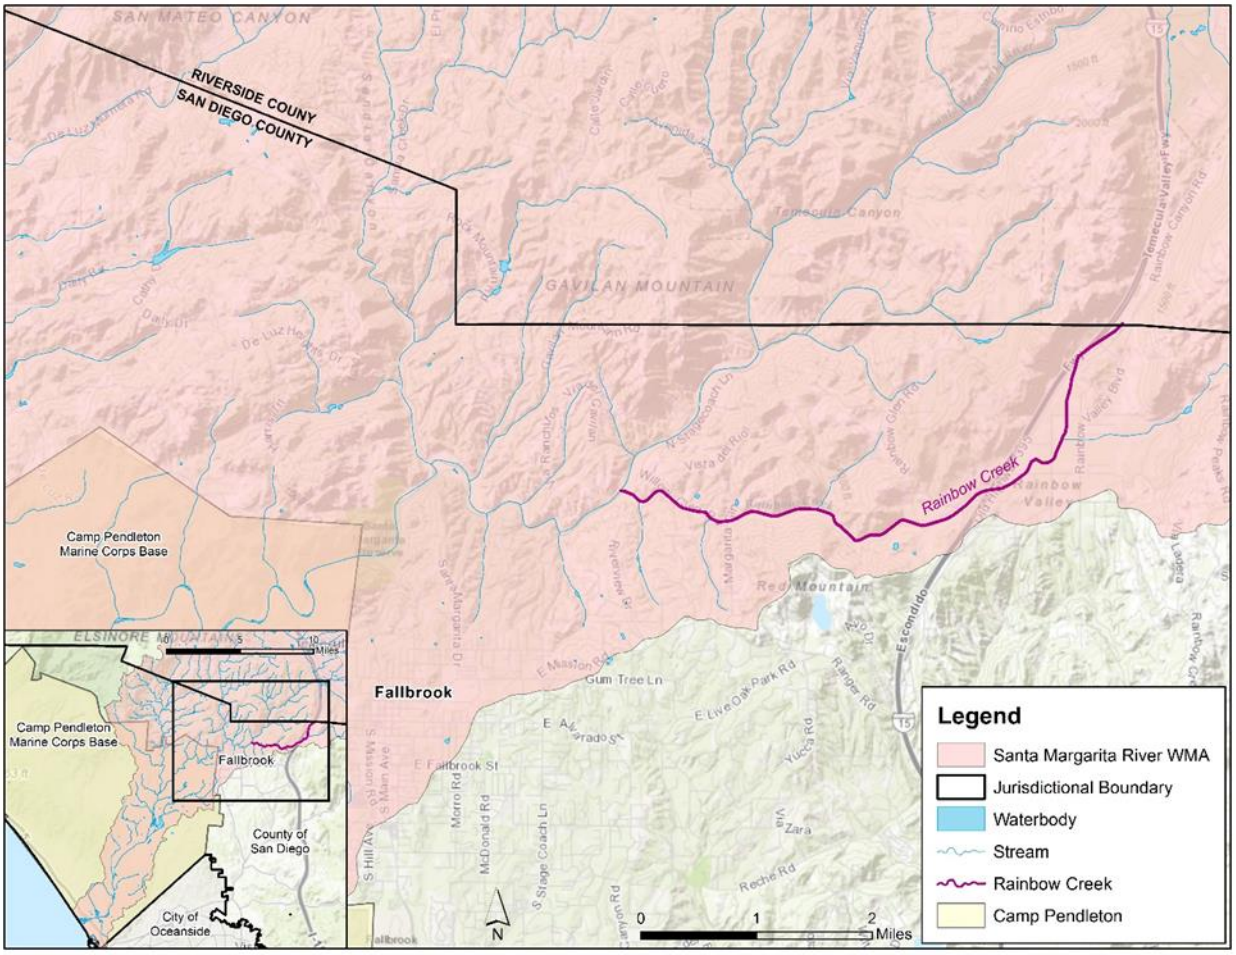

Figure 4-2. 303(d) Listed Segment of Rainbow Creek in the Santa Margarita River WMA

Water quality objectives (WQOs) for biostimulatory substances that are established by the Basin Plan (Regional Water Board, 1994) require that the substances remain below concentrations that promote algal growth to the extent that causes nuisance or adversely affects beneficial uses. The Rainbow Creek Nutrient TMDL is based on the numeric interpretation of the narrative Basin Plan WQOs for biostimulatory substances for the protection of the COLD and WARM beneficial uses: total nitrogen (1.0 milligrams per liter [mg/L] and total phosphorus 0.1 mg/L). The Basin Plan establishes that waters designated with the MUN beneficial use must not contain concentrations of nitrate in excess of the maximum contaminant levels (MCLs) set forth in California Code of Regulations Title 22. The MCL for nitrate (as nitrogen) is 10 mg/L.

4.1.3.3.2 Goals and Schedules for HPWQC Nutrients in Rainbow Creek

To comply with the Nutrient TMDL, the Permit provides multiple compliance pathways either regarding the receiving water or in stormwater discharges. Attachment E.3 of the Permit allows any of these pathways to achieve compliance (i.e., demonstration of progress toward all compliance pathways is not required), so the compliance pathways are independent of each other. The compliance pathways are based on three types of metrics:

(1) Receiving water conditions that are evaluated by comparing measured conditions with WQOs;

(2) Conditions of discharges from the MS4 outfalls that are evaluated by comparing measured conditions to WQO load reductions; and,

(3) Implementation of the WQIP (i.e., establishment of goals, implementation of strategies and schedules).

Compliance with the final water quality-based effluent limitations (WQBELs), on or before the final Nutrient TMDL compliance date, may be demonstrated via one of the following methods (Regional Water Board, 2013):

(1) There is no direct or indirect discharge from the Copermittees' MS4s to the receiving water; or

(2) There are no exceedances of the final receiving water limitations under specific Permit Provision 3.b.(2)(a) in the receiving water at, or downstream of the Copermittees' MS4 outfalls; or

(3) There are no exceedances of the final effluent limitations under specific Permit Provision 3.b.(2)(b)(i) at the Copermittees' MS4 outfalls; or

(4) The annual pollutant loads from given land uses discharging to and from the MS4s do not exceed the final effluent limitations under specific Permit Provision 3.b.(2)(b)(ii); or

(5) The Copermittees develop and implement the WQIP as follows:

   (i) Incorporate the BMPs required under specific Permit Provision 3.b.(2)(c) as part of the WQIP;

   (ii) Include an analysis in the WQIP, utilizing a watershed model or other watershed analytical tools, to demonstrate that the implementation of the BMPs required

under specific Permit Provision 3.b.(2)(c) achieves compliance with specific Permit Provisions 3.b.(3)(a), 3.b.(3)(b), 3.b.(3)(c) and/or 3.b.(3)(d);

(iii) The results of the analysis must be accepted by the Regional Water Board as part of the WQIP;

(iv) The Copermittees continue to implement the BMPs required under specific Permit Provision 3.b.(2)(c); and

(v) The Copermittees continue to perform the specific monitoring and assessments specified in specific Permit Provision 3.d, to demonstrate compliance with specific Permit Provisions 3.b.(3)(a), 3.b.(3)(b), 3.b.(3)(c) and/or 3.b.(3)(d).

The final numeric goals for nutrients in Rainbow Creek, developed based on final effluent limitations for receiving waters and MS4 discharges outlined in Attachment E.3 of the Permit, are presented in **Table 4-4**.

Table 4-4. Numeric Goals and Schedules for HPWQC – Nutrients in Rainbow Creek, San Diego County[16]

Compliance Pathway			Numeric Goal (December 31, 2021)
Water Quality Improvement Plan Implement Accepted Water Quality Improvement Plan			Implementation of a Water Quality Improvement Plan that incorporates the required BMPs; includes an analysis utilizing a watershed model or other watershed analytical tool to demonstrate that the implementation of the required BMPs achieves compliance; the results of the analysis are accepted by the Regional Water Board as part of the Water Quality Improvement Plan; the responsible Copermittees continue to implement the required BMPs; and the responsible Copermittees continue to perform the specific monitoring and assessments to demonstrate compliance.
OR			
Receiving Water Meet Receiving Water Limitations	Nitrate (as N)		10 mg/L

		Parks	0.10 kg/yr
		Residential Areas	12 kg/yr
		Urban Areas	6 kg/yr

[16] See Order R9-2013-0001, as amended, Attachment E.3 – Total Maximum Daily Loads for Total Nitrogen and Total Phosphorus in Rainbow Creek Watershed.

4.2 STRATEGIES AND SCHEDULES

By building on the potential strategies developed consistent with Permit Provision B.2.e (**Appendix 3B**), each Copermittee and the City of Menifee has identified a group of strategies, consistent with Permit Provision B.3.b, that will be implemented within their jurisdiction and identified optional watershed management strategies for consideration to address eutrophication in the SMR watershed. Strategies to address eutrophication focus on reducing the discharges of nutrients, but also include strategies that change the physical factors in the receiving water to reduce the growth of algae and/or improve dissolved oxygen conditions (e.g. restoration of stream channels).

Strategies[17] to meet final goals were selected on the basis of their ability to achieve the following specific objectives:

- Effectively prohibit non-storm water discharges from the MS4 to receiving waters;
- Reduce pollutants in storm water discharges from the MS4 to the maximum extent practicable (MEP); and
- Implement programmatic or institutional BMPs.

The implementation of the WQIP will prioritize non-structural BMPs initially, with an emphasis on those that most directly address sources of nutrients. Source control measures will be implemented early on to address flows during dry weather by eliminating prohibited non-storm water discharges. Wet weather load reductions will be achieved through an iterative adaptive management process. Both non-structural and structural BMPs will be implemented as necessary, as applicable approvals are granted and funds are secured.

Within this larger framework, priorities for strategy selection include:

- BMP effectiveness, particularly for targeting nutrients, with consideration for priority water quality conditions;
- Provision of multiple benefits, including but not limited to, habitat, recreation, economic, and water resources benefits; and,
- The degree to which the strategy is sustainable, implementable, and cost-effective.

Given the varied sources within each jurisdiction, sets of strategies were developed specific to each Copermittee and the City of Menifee for each HPWQC, and are presented in the following subsections. Strategies include jurisdictional, optional jurisdictional and optional WMA strategies for each agency. Each Copermittee will implement JRMP (jurisdictional) strategies (to meet Permit Provisions E.2 through E.7), and the City of Menifee will implement its jurisdictional LIP strategies. Additionally, each Copermittee and the City of Menifee will implement additional

[17] Water quality improvement strategies selected for this Water Quality Improvement Plan may be categorized as either non-structural or structural BMPs (including both distributed and regional BMPs). Non-structural BMPs are management actions or programs designed to reduce or eliminate pollutant loading at the source. Non-structural BMPs can be municipal programmatic or regulatory measures, public education and outreach, financial incentives, or other source management programs designed to affect behavioral changes. Structural BMPs are treatment or volume mitigation BMPs implemented at the neighborhood (i.e., regional), parcel, or site scale (i.e., distributed) and include features such as green streets, rainwater harvesting, and Low Impact Development (LID)-type solutions. Funding sources for the implementation of structural BMPs have not been identified.

strategies (optional jurisdictional and optional WMA strategies), as described in Permit Provisions B.3.b(1)(a)(i)-(vi). WMA strategies may be implemented by multiple agencies.

4.2.1 Strategies to Address Eutrophication in the Upper and Middle SMR Subwatershed

This section describes the overall approach to strategy selection, prioritization, and implementation, the selected strategies, and a schedule for strategy implementation. The goals are developed to demonstrate progress towards addressing the HPWQC, but the strategies were developed to address the HPWQC, as well as other priority water quality conditions identified in **Chapter 2**. There are many strategies that will be implemented throughout the Middle SMR Subwatershed. In addition, Copermittees will select "targeted areas" for implementation of specific, focused strategies, to address the HPWQC (eutrophication impacts in the SMR Estuary, Warm Springs, and Redhawk Channel and nutrient loadings to the SMR Estuary from Upper Murrieta Creek and Tributaries, Warm Springs, Santa Gertrudis, Murrieta Creek and Long Canyon, Temecula Creek and Redhawk Channel). Strategies have been developed at jurisdictional (jurisdictional and optional jurisdictional strategies) and watershed scales (optional WMA strategies).

4.2.1.1 Approach to Strategy Selection and Implementation

The Copermittees and the City of Menifee have developed an adaptive approach for addressing the HPWQC which consists of a process for selecting, evaluating and implementing jurisdictional, optional jurisdictional, and optional WMA strategies based on program effectiveness assessments and data gathered through the monitoring program and special studies. The strategies will address the eutrophication and the effects of nutrient loading for the watershed.

Strategies were developed to target specific sources of nutrient loading to the MS4, particularly during dry weather conditions, consistent with the HPWQC. As described in **Chapter 3**, each agency has prioritized potential sources of nutrients within its jurisdiction. Based on this analysis, the top sources of nutrient loading to the MS4 within the Middle SMR Subwatershed include residential areas; commercial facilities; orchards, vineyards, and nurseries; and horse ranches. Strategies were developed to address these specific sources, as appropriate, in each jurisdiction.

The approach to the initial strategy selection and implementation is shown in **Figure 4-9**, and consists of the following steps:

- **Each Copermittee and the City of Menifee Will Implement JRMP/LIP Programs Throughout Their Jurisdiction –** Each Copermittee and the City of Menifee will develop and implement a JRMP or LIP (City of Menifee only) that contains strategies to address the requirements in Provisions E.2 through E.7 of the Permit. Jurisdictional programs, strategies, and minimum BMPs established per each agency's JRMP or LIP (City of Menifee only) will be implemented across all areas within the respective jurisdiction within 90 days of the Regional Water Board's acceptance of the WQIP. During JRMP and LIP revisions, proceeding concurrently with development of the WQIP, the JRMPs and LIPs will incorporate WQIP strategies designed to address nutrient loading to the MS4. Where practical, the JRMPs/LIPs will incorporate strategies that are designed to provide multiple benefits; that is, they will address eutrophication impacts and nutrients but will often also address one or more of the PWQCs (e.g., bacteria). JRMPs for each Copermittee in the Middle SMR Subwatershed are available at the following web link:

www.rcflood.org/npdes/SantaMargaritaWS.aspx#SMdocs. The City of Menifee will implement strategies described in its LIP, developed under their governing MS4 Permit in the Santa Ana Region (Order No. R8-2010-0033, NPDES Permit No. CAS618033).

- **Identify Target Areas to Implement Strategies to Address Specific Sources of the HPWQC –** In addition to the JRMP/LIP strategies to be implemented throughout each jurisdiction, additional strategies will be implemented to address sources of the HPWQC as required by Permit Provision B.3.b.(1)(a)(i)-(vi) (collectively referred to as enhanced JRMP/LIP strategies). In order to best address the priority sources identified in **Chapter 3**, the Copermittees identified target areas for implementation to focus on known and suspected sources of nutrients. Target areas within the SMR watershed were identified using several factors that are expected to correlate with nutrient loading discharged through the MS4. Factors used in target area selection are illustrated in **Figure 4-3**.

1. Based on models developed as part of the TMDL Alternative.
2. Information related to overwatering is supported by water usage data where available through coordination with local water districts.
3. Based on available data as discussed in Chapter 2.

Figure 4-3. Factors Considered When Selecting Target Areas

Copermittees in the Middle SMR Subwatershed selected five target areas to focus implementation. Due to their small land area and lack of MS4 outfalls, the City of Menifee did not select specific target areas. RCFCWCD also did not select target areas, as they do not have land use authority in many of the areas draining to their MS4. The selected target areas are illustrated for each Copermittee in **Figure 4-4** through **Figure 4-8**, with a figure for RCFCWCD illustrating the drainage areas contributing to their dry weather outfall monitoring locations. Consistent with an adaptive management approach, as more information becomes available, target areas may be modified to focus strategy implementation as appropriate. A diagram of the strategy implementation process for the upcoming permit term is illustrated in **Figure 4-9**.

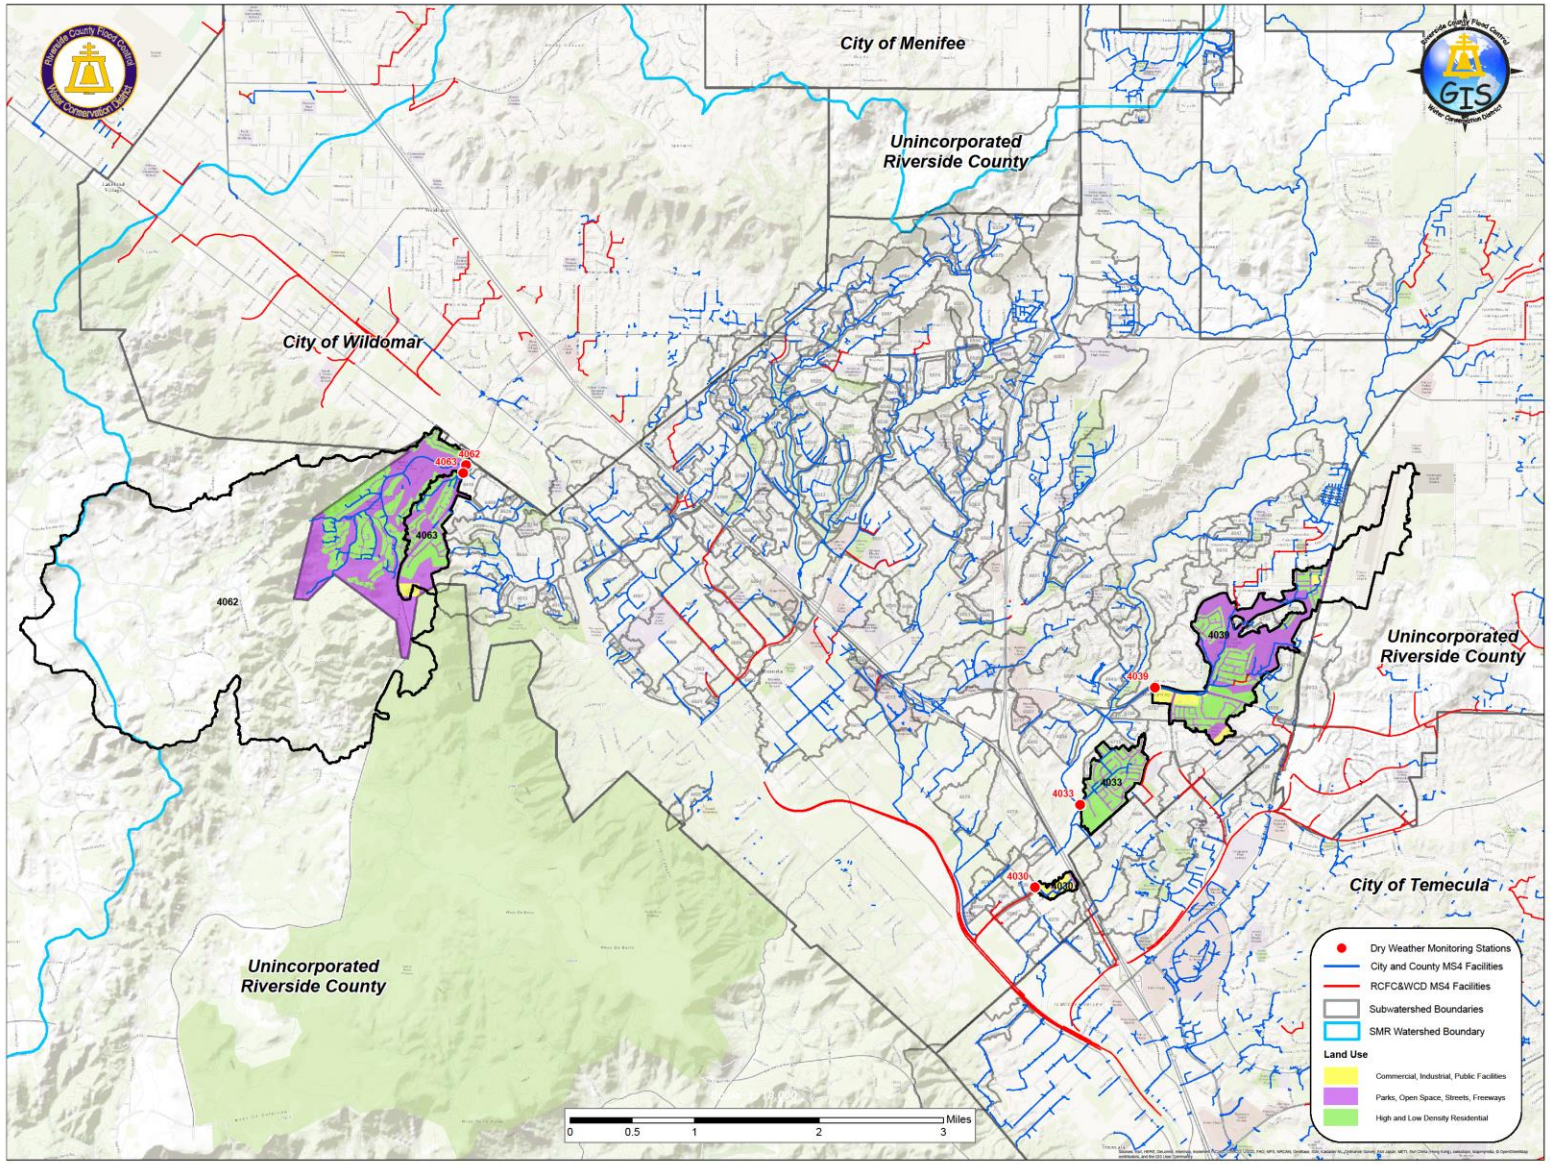

Figure 4-4. City of Murrieta Target Areas

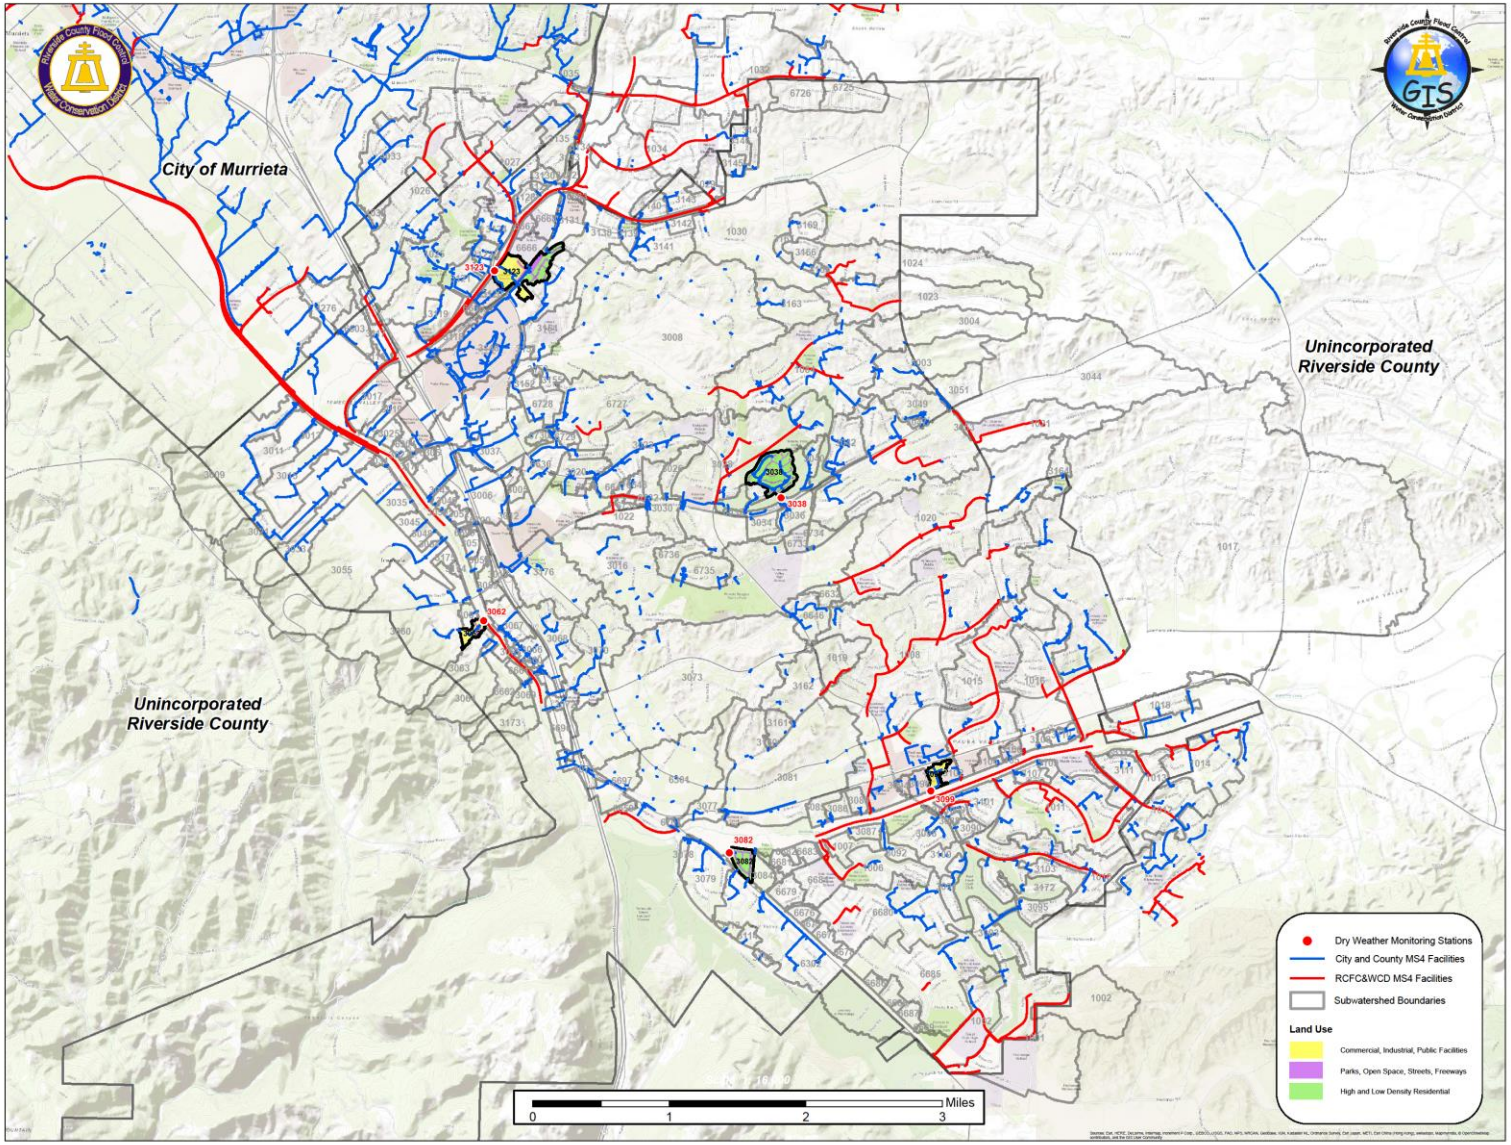

Figure 4-5. City of Temecula Target Areas

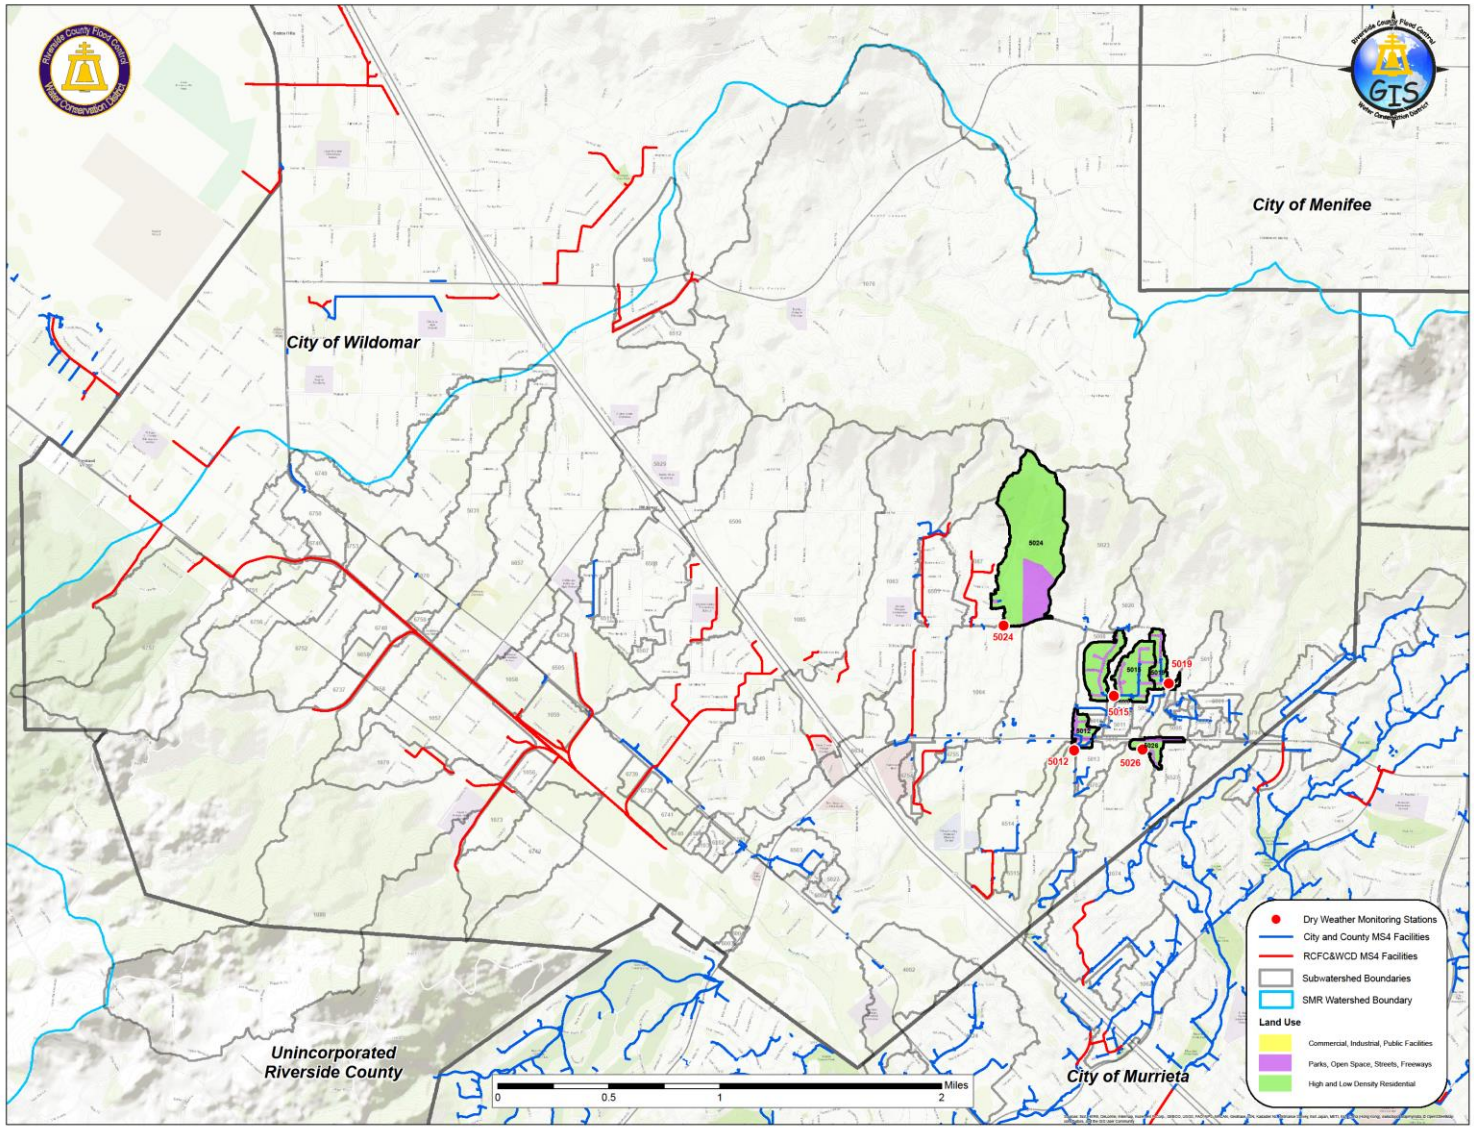

Figure 4-6. City of Wildomar Target Areas

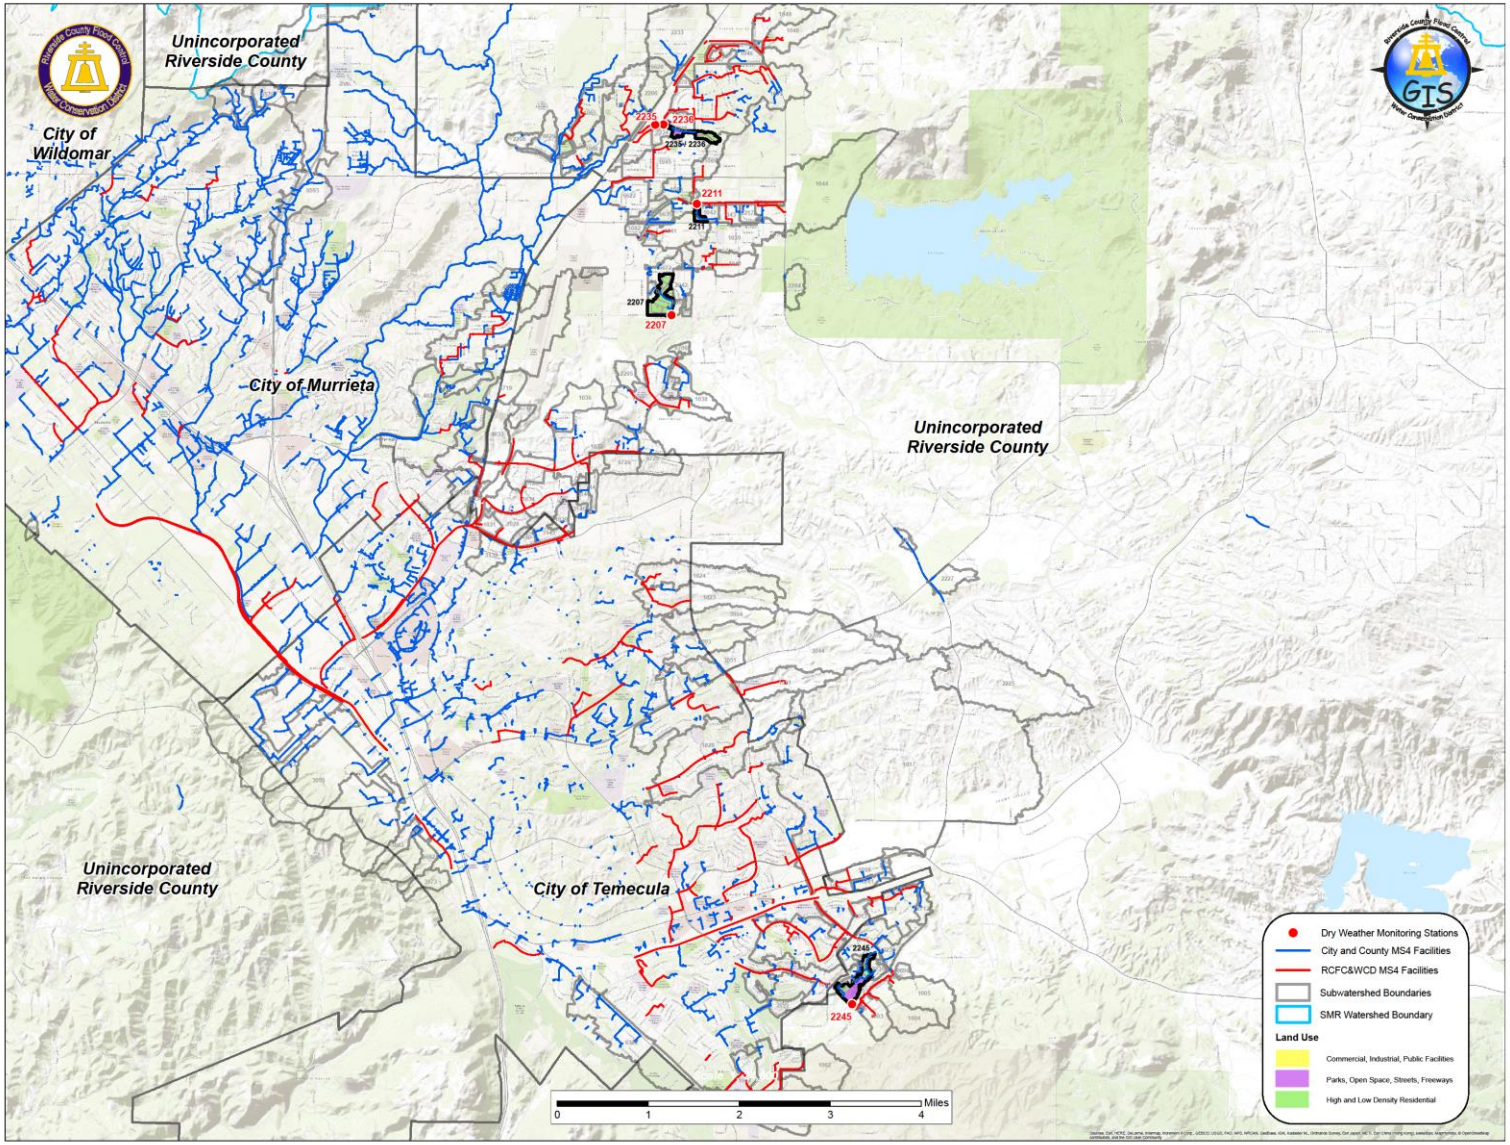

Figure 4-7. County of Riverside Target Areas

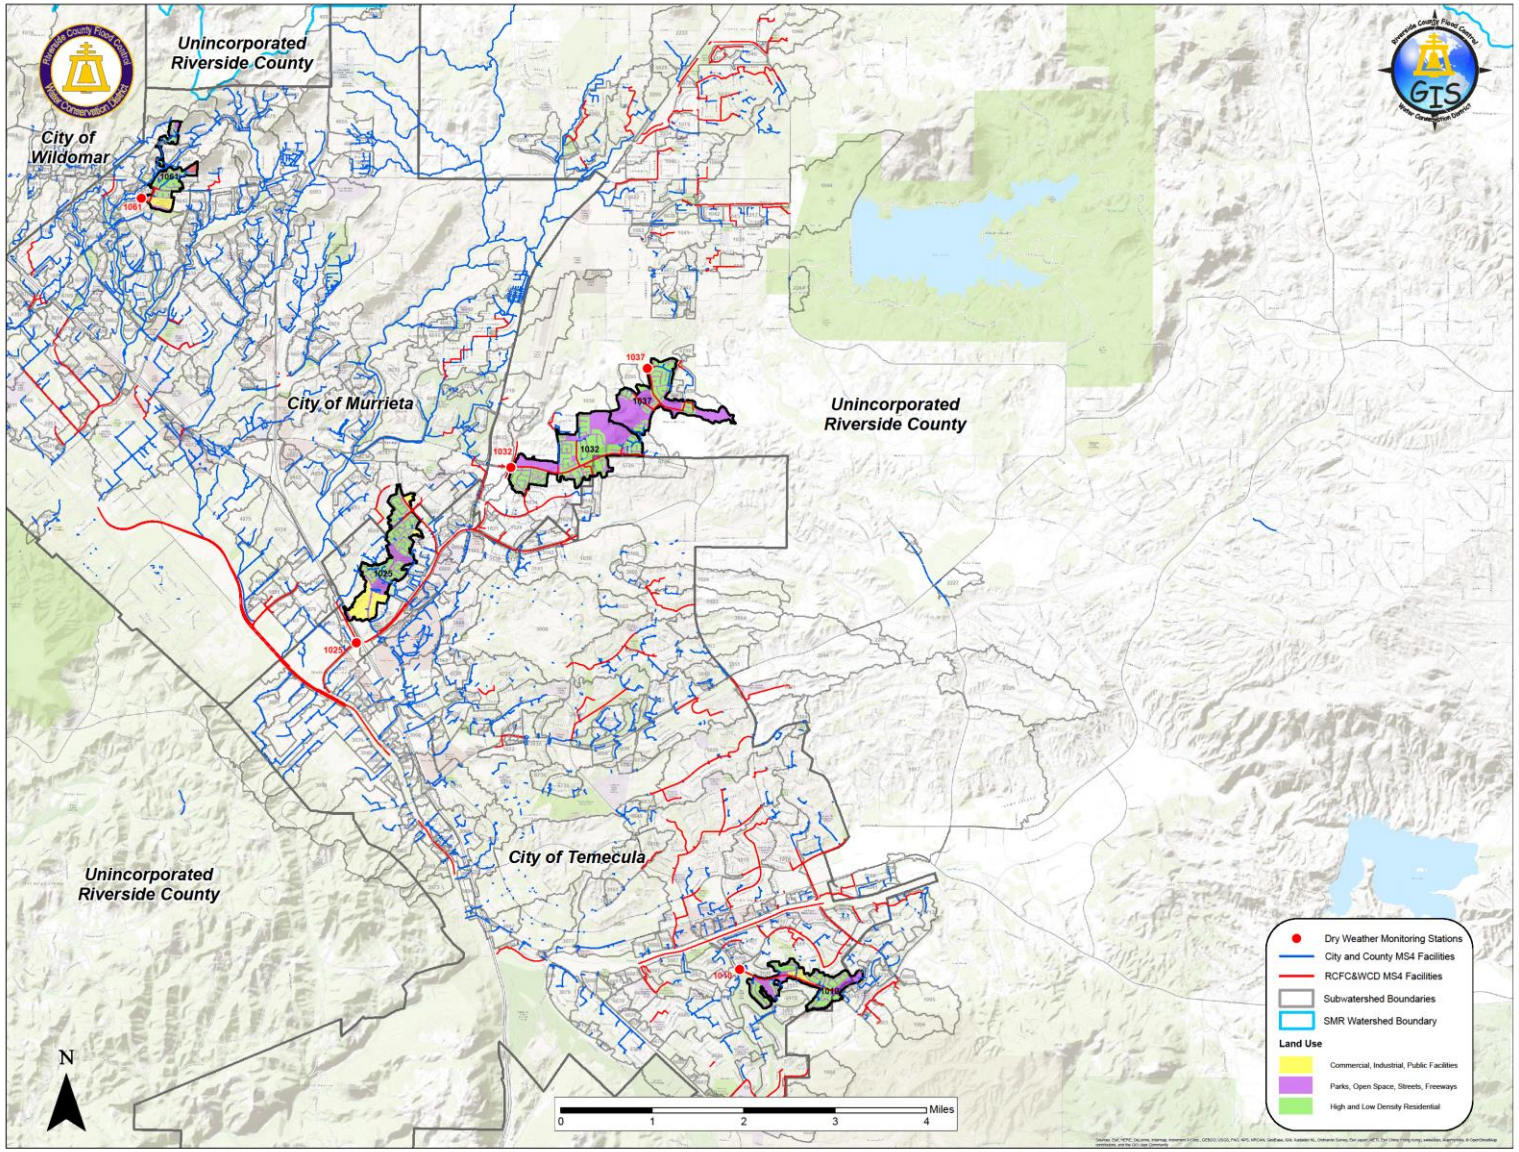

Figure 4-8. Riverside County Flood Control and Water Conservation District Dry Weather Outfall Monitoring Locations

- **Implement Enhanced JRMP/LIP Strategies in Target Areas** – Strategy implementation will include enhanced JRMP strategies that address Permit Provision B.3.b.(1)(a)(i)-(vi). Enhanced strategies are specific, locally appropriate strategies, focused in target areas where there are potential sources of nutrients contributing flows to the MS4.
    - Each Copermittee will implement enhanced JRMP/LIP strategies within their target areas. Each Copermittee has identified an initial set of enhanced strategies within applicable JRMP programs that focus on the nutrient sources within their jurisdiction, summarized in **Table 4-6** through **Table 4-11**.
    - Details of the enhanced JRMP strategies selected by each Copermittee are included in their jurisdictional strategies tables.
- **Implement Optional Jurisdictional/Optional WMA if triggered** – The Copermittees will employ an adaptive approach to implement and evaluate strategies. The Copermittees have developed optional watershed strategies that, if triggered and resourced, would be implemented through coordination amongst the Copermittees. At the time of each update of the WQIP (not less than every five years), assessments will be made regarding the degree of implementation of identified strategies versus the measured progress toward interim and final goals. If the percent of implementation is significantly higher than the percentage of the final goal achieved, jurisdictional strategies may be modified, additional enhanced strategies may be selected, or optional strategies (jurisdictional or WMA) may be triggered.

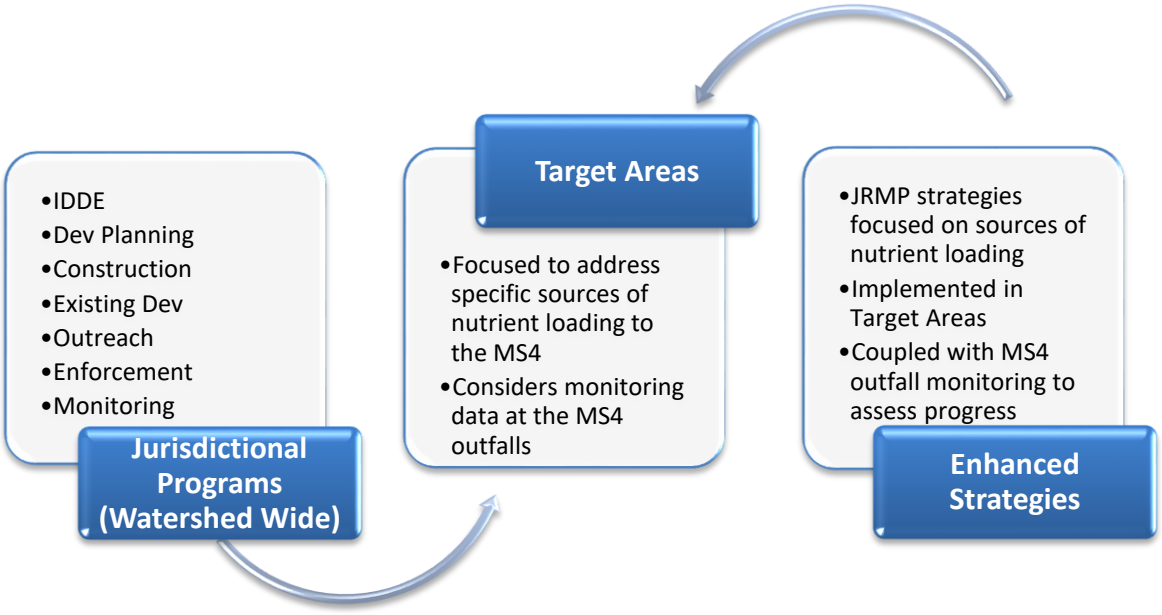

Figure 4-9. Initial Strategy Selection and Implementation, 2018 - 2023

In summary, the strategies can be categorized into three types:

1. Strategies building on the required JRMP elements in Provision E of the Permit. These include the JRMP requirements, as well as modifications and enhancements within existing programs to provide a more focused approach to specifically address sources contributing to nutrient loading and eutrophication;
2. Optional jurisdictional strategies designed to address nutrient loading and eutrophication that may be necessary to achieve goals; and
3. Optional WMA strategies involving cooperation amongst two or more Copermittees or the City of Menifee working together to address nutrient loading and eutrophication.

The strategies include suites of programmatic (i.e., non-structural) and structural BMPs that are expected to improve conditions within the watershed. The Copermittees and the City of Menifee have placed an emphasis on selecting strategies that achieve multiple-pollutant reductions, and, thus, are effective at addressing other priority water quality conditions in addition to nutrients. An overview of the adaptive management options are illustrated in **Figure 4-10**.

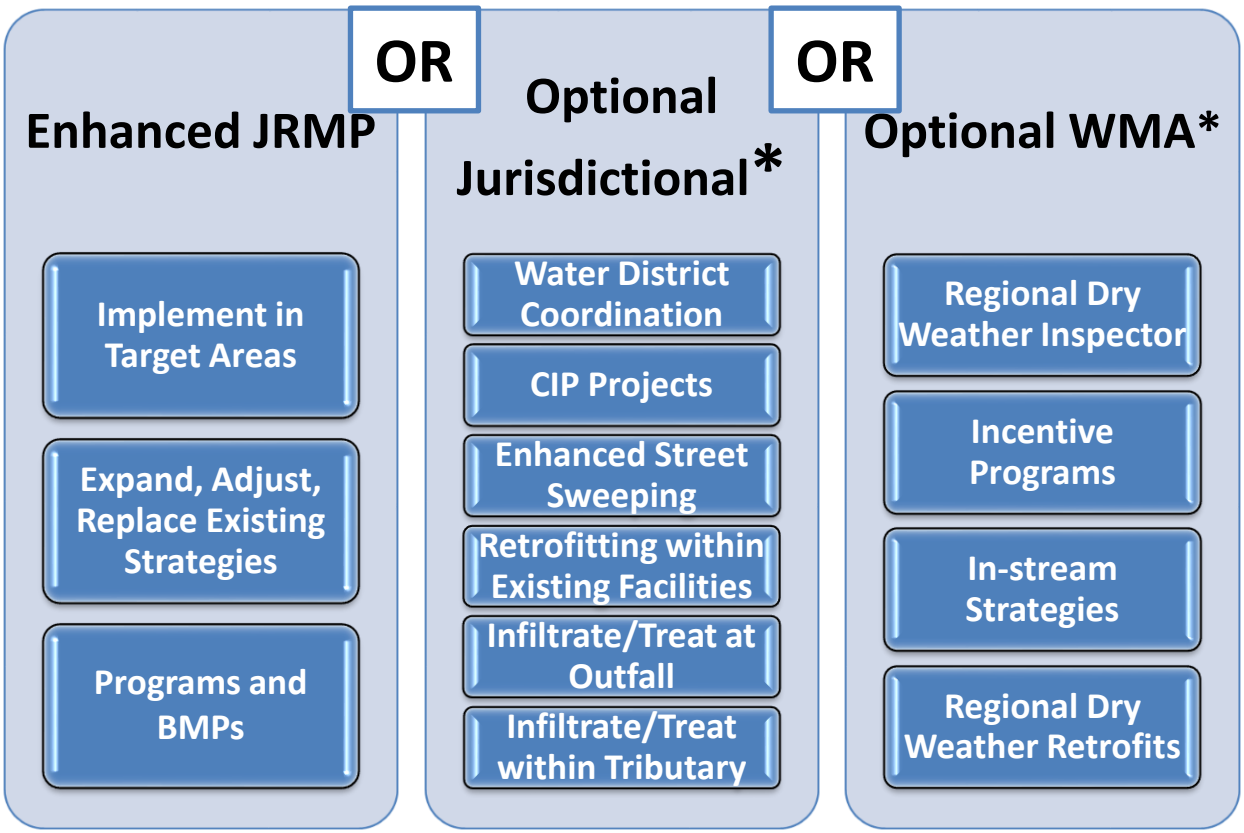

Figure 4-10. Adaptive Management Options (*as triggered and resourced)
[*see Optional Strategies Table and Jurisdictional Tables for Complete List*]

4.2.1.2 Jurisdictional Strategies

The Copermittees and the City of Menifee have identified jurisdictional strategies that will be implemented as part of their JRMP that are designed to effectively prohibit non-storm water discharges to the MS4, reduce pollutants in stormwater, and protect beneficial uses of receiving waters. Implementation of JRMP strategies and their success will ultimately be measured against the interim and final numeric goals as discussed in **Section 4.1**.

When selecting enhanced JRMP strategies, the most effective BMPs for each program will depend on characteristics of each jurisdiction (e.g., jurisdiction size, types of activities, land uses, sources); therefore, all jurisdictions will not necessarily implement the same strategies nor implement strategies on the same scale. For example, it is expected that all Copermittees and the City of Menifee will have enhanced strategies to focus on residential areas, since that is one of the highest priority sources for all; however, commercial nurseries are only present in some jurisdictions, so only those would have enhanced strategies focused on these sources. From a geographic perspective, enhanced strategies will be focused on areas where they are likely to be most effective. These enhanced strategies will be based on existing JRMP programs and permit requirements and, through the WQIP, will be tailored to the conditions within the jurisdiction that may contribute to nutrient loading and eutrophication impacts. As an example, existing development programs implemented under Permit Provision E.5 may be tailored to target specific sources identified as priorities within a jurisdiction, such as residential areas, commercial nurseries, or horse ranches. As discussed in **Chapter 3**, the Copermittees and the City of Menifee identified and prioritized suspected sources that contribute to nutrient loading. The Copermittees and the City of Menifee used that information when developing their jurisdictional programs to focus on the sources that could potentially contribute nutrients through the agencies' MS4s.

Enhanced strategies are specific, locally appropriate strategies, focused in target areas where there are sources contributing to eutrophication or nutrient loading to the storm drain system.

The Copermittees' jurisdictional programs, per Permit Provisions E2 – E7, and how they address sources of nutrients and eutrophication impacts are described below.

4.2.1.2.1 Illicit Discharge Detection and Elimination [Permit Provision E.2]

The Permit requires the effective prohibition of non-stormwater discharges through implementation of programs under Provision E.2, illicit discharge detection and elimination (IDDE). The IDDE program is intended to minimize the impacts of illicit discharge and connections to receiving waters through investigations, water quality monitoring at MS4 outfalls, and follow-up activities to abate sources of illicit discharges. This program is fundamental in effectively prohibiting non-stormwater discharges. Programs required under this provision are currently being implemented by the Copermittees and will continue. The programs can be enhanced to focus municipal training programs that target key staff regarding the effects of nutrient discharges on receiving waters in the watershed and on identifying sources of illicit discharges (e.g., residential areas, commercial nurseries) that potentially contribute nutrients. The enhanced training efforts will focus on identifying and eliminating non-stormwater flows, since that will reduce nutrient loading and address persistent dry weather flows in outfalls.

While the focus is on nutrients, IDDE programs and enhanced strategies will address multiple pollutant sources and constituents through reduction and elimination of non-stormwater flow. The Copermittees maintain inventories of commercial, industrial, residential, and municipal facilities, all of which can contribute to illicit discharges and nutrient loads. Specifically, Copermittees will focus on inventoried facilities likely to have non-stormwater discharges resulting from over-irrigation, such as commercial facilities, residential areas, and municipal parks. The Copermittees will focus on land uses that meet the following criteria: 1) the land use is likely to be over-irrigated, and 2) areas tributary to a MS4 facility.

Inspections are performed on an as-needed basis as part of the IDDE program, most often in response to complaints from municipal staff or residents, or as a result of field investigations. Inspections will continue to be performed on an as-needed basis, but may be performed on a more frequent basis in response to outfall screening results and assessments in targeted areas aimed at eliminating non-stormwater flows.

4.2.1.2.2 Development Planning [Permit Provision E.3]

The previous municipal stormwater permit in 2010 (Order No. R9-2010-0016) designated specific types of new development and redevelopment projects as "priority development projects" or PDPs, requiring specific site design, source control, and structural treatment control BMPs to be implemented for qualifying projects. The 2010 Permit also required certain PDPs to implement controls to mitigate increases in peak flow and volumes of stormwater. With the 2015 Permit, these requirements were further intensified with the new requirement for full on-site retention of the 24-hour, 85th percentile storm volume. With limited exceptions, new development and redevelopment projects are required to retain or treat and detain stormwater and its associated pollutants (including nutrients) on-site, to reduce the impacts on receiving waters during storm events. In most cases, the post-construction BMPs are also designed to intercept and infiltrate dry weather flows, providing significant pollutant reduction, and often full elimination under ambient conditions. The implementation of baseline Permit requirements for new development and redevelopment projects will mitigate pollutants (including nutrients and other PWQCs) and ensure that these projects do not cause degraded water quality conditions downstream of the project site.

In addition to the baseline requirements, the Copermittees may implement enhanced strategies as part of the Development Planning program that will focus efforts on mitigating sources of nutrients. The enhancements could include modified LID requirements, smart irrigation conditions of approval, and/or revised post-construction guidelines to eliminate dry weather discharges from new development and redevelopment. In addition, development standards and guidelines could be developed or updated to eliminate dry weather discharges; promote swale grading and reduce the use of private area drains directly connected to the curb; and/or require BMPs or catch basins at all site entrances and exits which are sloped towards public right-of-way to ensure that any dry weather run-off is routed to an on-site treatment system. Copermittee BMP design manuals could be amended to address priority sources (e.g., over-irrigation in residential areas) supplemented by internal staff training on updated BMP design manual or other enhancements that target nutrients.

The Copermittees maintain inventories and perform inspections of treatment control BMPs to verify that the required BMPs are constructed properly, maintained appropriately, and operating as designed. Copermittees will continue to inventory and inspect treatment control BMPs as required under Permit Provision E.3. Through this program, it is anticipated that non-stormwater flows (and, therefore, any nutrients in the non-stormwater flows) will be reduced or eliminated

from new development and redevelopment and that nutrients in stormwater will be reduced through biofiltration, retention, or other BMPs. As new development and redevelopment continues, increased amounts of the existing landscape will have treatment control BMPs and contribute less to nutrient loads and other PWQCs identified in **Chapter 2**.

4.2.1.2.3 Construction Management [Permit Provision E.4]

Construction sites have the potential to contribute to nutrient loading primarily through ineffective erosion control that can lead to phosphorous-borne sediment entering the receiving waters. The Copermittees have been implementing construction stormwater programs for several NPDES permit terms. Over this time, agency staff and the construction community have become well trained in construction stormwater management. Additional oversight is required per the State Construction General Permit (Order 2009-0009-DWQ) for sites greater than one acre. With this amount of focus, the limited sources of nutrients related to construction are well addressed via the existing Permit requirements. For this reason, the Copermittees will focus on the baseline programs as required under the 2013 Permit. These requirements include a set of minimum BMPs for construction sites, articulated in each Copermittees' JRMP, and routine inspections of construction sites to ensure that BMPs are implemented as required. Where necessary, enforcement measures may be used to gain compliance.

4.2.1.2.4 Existing Development Management [Permit Provision E.5]

The Existing Development Management program requires comprehensive inventories, periodic inspections, and enforcement for existing development (i.e., commercial, industrial, municipal, and residential) to ensure that BMPs are implemented to reduce water quality pollutants and runoff. This program also includes municipal operations and maintenance practices, such as storm drain cleaning and street sweeping. The source prioritization in **Chapter 3** will be used in conjunction with Copermittee inventories to identify and target specific sources potentially contributing to the eutrophication impacts and nutrient loading. Existing development programs will be implemented per Permit Provision E.5 and may also include enhanced strategies (e.g., increased inspection frequencies for facilities, with the potential to contribute nutrients, included in the inventories). Select strategies within the Existing Development Management Program that the Copermittees identified for addressing nutrients, and other priority water quality conditions, are described below.

4.2.1.2.4.1 Street Sweeping

Street and median sweeping is a common practice for reducing street sediment and vegetative and anthropogenic debris, and, therefore, urban runoff pollutant loads from transportation land uses. High-efficiency street sweeping equipment, such as regenerative air sweepers or vacuum assisted sweepers can significantly increase the amount of sediment removed from roadways. Street and median sweeping within the watershed may be an effective program for managing the sediment transport of pollutants (e.g. nutrients, metals, oil and grease, bacteria) into the MS4. Street sweeping BMPs provide water quality benefits for multiple pollutants of concern through transportation-related source load mitigation and the removal of multiple associated pollutants. Street sweeping is currently implemented per each Copermittee's JRMP, but may also be selected as an enhanced strategy and implemented at higher frequencies within targeted areas. Street sweeping addresses improved areas of existing development (e.g., residential, commercial, industrial, municipal areas with curb and gutter).

4.2.1.2.4.2 Existing Development Inspections

The source evaluation and prioritization in **Chapter 3** included inventories of potential sources contributing to eutrophication impacts and/or nutrient loading. Specific potential sources include industrial and commercial facilities, especially those with irrigation systems, residential areas, municipal facilities, such as parks and recreation areas, onsite wastewater treatment systems, sanitary sewer systems, streets, and landfills. The Copermittees could choose to enhance their inspection programs to focus on sources that potentially contribute to nutrient loading within the selected target areas as part of their enhanced JRMP Programs. The enhancements may include increasing inspection frequencies at facilities identified to be potential sources of nutrients within the target areas, beyond the minimum requirements in the Permit of once every five years.

In addition, the focus of both residential and commercial/industrial programs will be targeted toward identifying and eliminating over-irrigation to better address nutrient loading from irrigation runoff. Areas identified as sources will be targeted through tailored and enhanced inspections. Through inspections, the Copermittees can conduct outreach to home and business-owners about smart irrigation controllers and/or other financial incentive programs that decrease watering volume. Effective methods to reduce irrigation runoff from residential, commercial, and agriculture may include development of targeted outreach materials, increased inspections surveys, punitive measures for overwatering, tiered water rates, or distribution of smart irrigation controllers and/or other financial incentive programs that decrease watering volume. Irrigation runoff reduction programs can also be integrated with BMPs that encourage landscaping and smart gardening practices that reduce the load of fertilizers and chemicals that enter stormwater, such as integrated pest management, reducing fertilizer and pesticide use, xeriscaping, and turf conversion. To facilitate the use of these source control approaches, ordinances, education and outreach, and financial incentives may be implemented. Increased irrigation runoff controls and incentives in commercial and residential land uses could result in pollutant load reductions at the MS4 outfalls.

Additionally, areas of existing development where erosion is identified as a potential problem will be evaluated and addressed as appropriate since nutrient loads can increase as a function of sediment transport during wet weather events.

4.2.1.2.4.3 Inspection of Onsite Wastewater Treatment Systems (OWTS)

Leaking or failing septic systems may contribute to nutrient loads and other PWQCs (e.g., bacteria) during dry and wet weather conditions. Approximately 1,500 acres of land within the watershed are known to contain septic systems. In selected targeted areas, the Copermittees could enhance their residential programs to add a focus on failing septic systems (e.g., focused internal training for field staff). An effective septic survey and enforcement program addresses nutrients and other PWQCs by preventing the transport of nutrients, sediment, and bacteria from failing OWTS to MS4s and surface waters.

4.2.1.2.5 Enforcement Response Plans [Permit Provision E.6]

The use of enforcement actions to correct violations will support existing programs and enhanced strategies across all JRMP programs and has been shown to increase their effectiveness. Enforcement activities, such as inspections or escalating enforcement responses to compel compliance with statutes, ordinances, permits, orders, and other requirements, could significantly increase the success of other BMP programs (e.g., IDDE, existing development). Escalating

enforcement actions will be implemented in accordance with each Copermittee's enforcement response plan, developed per Permit Provision E.6 and included in their JRMP.

4.2.1.2.6 Public Education and Participation [Permit Provision E.7]

The Public Education and Participation programs are an integral part of program implementation, targeting key internal (i.e., Copermittee staff) and external (i.e., public) audiences that may contribute to nutrient loading or other PWQCs identified within the watershed. Public education and participation is an important approach to heighten watershed stewardship and mindfulness of water quality. The Copermittees develop and distribute outreach materials; perform outreach presentations at public events; provide outreach to large residential properties and mobile landscaping businesses; and provide educational workshops. More recently, some Copermittees are beginning to use social media as an outreach mechanism. The enhanced strategies related to education and participation will focus on sources of nutrients (e.g., nurseries, homeowners' associations, septic systems), but will provide a multi-pollutant benefit in promoting general water quality awareness. Examples of outreach strategies that Copermittees may implement to address nutrient loading and potential sources include:

- Incentive programs (e.g., for irrigation runoff reduction in coordination with water districts);
- Encouraging BMPs that include landscaping and smart gardening practices that reduce the load of fertilizers and chemicals that enter stormwater; and
- Promoting integrated pest management by reducing fertilizer and pesticide use, increasing xeriscaping, and implementing turf conversion.

Programmatic approaches, primarily non-structural BMP implementation, through the JRMP programs and enhanced WQIP strategies, form the basis for anticipated improvements in the watershed. These programs are focused on the key sources identified in **Chapter 3**. The key sources for each Copermittee and the relative loading of nutrients from those sources to the Copermittee's MS4s provide the foundation for strategy selection. The priority sources and relative nutrient loading are summarized for each Copermittee in **Table 4-5**.

Overall, the identified strategies for the SMR watershed include robust jurisdictional programs that include baseline programs and enhanced strategies to minimize, to the maximum extent practicable, the effects of nutrients discharged through MS4 conveyances to receiving waters. Copermittees will continue to implement their baseline JRMPs per Permit Provisions E.1 – E.8. Due to their different programs under the Santa Ana MS4 Permit, the City of Menifee will implement strategies based on their LIP. Within target areas, Middle SMR Subwatershed Copermittees have selected enhanced strategies. Copermittee strategies are summarized in **Table 4-6** through **Table 4-11**.

Table 4-5. Summary of Key Sources of Nutrients by Agency

Copermittee	Key Sources	Total Nitrogen[1]	Total Phosphorus[1]
City of Menifee	Residential Areas/Activities Horse Ranches (Residential) Commercial Facilities	N/A[2]	N/A[2]
City of Murrieta	Residential Areas/Activities	66.20%	64.20%
	Commercial Facilities	10.00%	9.70%
	Orchards, Vineyards, Nurseries	5.90%	5.80%
City of Temecula	Residential Areas/Activities	71.70%	70.50%
	Commercial Facilities	13.20%	13.00%
	Industrial Facilities	7.50%	7.40%
City of Wildomar	Residential Areas/Activities	67.40%	61.00%
	Horse Ranches	3.70%	3.40%
	Commercial Facilities	3.60%	3.30%
County of Riverside	Residential Areas/Activities	35.60%	33.60%
	Orchards, Vineyards, Nurseries	27.60%	26.30%
	Horse Ranches	10.60%	10.00%
RCFCWCD	Residential Areas/Activities Commercial Facilities Orchards, Vineyards, Nurseries	N/A[3]	N/A[3]

1. As a percentage of the total loading to the Copermittee's MS4.
2. Under the Regional Water Board Designation Letter dated October 26, 2015 Menifee is required to participate in the development and implementation of the SMR WQIP and the implementation of any applicable TMDL. However, no specific load allocations have been assigned to Menifee. Menifee was not included in the modeling efforts. Because Menifee only has a small jurisdictional area in the WMA (less than 2 square miles), Menifee will participate in the overall load reduction by implementing its WQIP and LIP strategies.
3. Nitrogen and phosphorus loads for the RCFCWCD were not calculated or included in the SMRNIG model. Nonetheless, the RCFCWCD will implement their JRMP, including the strategies identified in Table 4-11 to address the HPWQCs and PWQCs. If determined necessary by the SMRNIG, loading estimates may be developed in the future, at which time, they will be included within the WQIP through the adaptive management process.

As programs and progress towards goals are assessed, Copermittees and the City of Menifee will implement an iterative process of implementing additional enhanced strategies, followed by optional jurisdictional and optional WMA strategies as necessary to achieve their goals. Structural solutions are included as optional jurisdictional and optional WMA strategies and will be considered through the adaptive management process as triggered.

Table 4-6. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – City of Menifee

(Note: Only a small portion of the City of Menifee totaling less than 1.3 square miles is located in the Santa Margarita River Watershed Management Area. This area consists primarily of residential area, the majority of which is rural residential properties larger than 2 acres.)

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)															
IDDE-1	Entire Jurisdiction	Illicit Discharges, mainly residential (e.g. discharges related to equestrian and livestock activities) and commercial (e.g. nursery activities) for the SMR WMA	Implement an Illicit Connection and Illegal Discharge (IC/ID) Program. LIP requirements include: maintaining an MS4 map, using municipal personnel and contractors to identify and report illicit discharges, maintaining a hotline for public reporting of illicit discharges, monitoring MS4 outfalls, and investigating and addressing any illicit discharges.	Both	X	X		X	X	X	X	X	X	Continuous	The City of Menifee conducts outfall monitoring per the Santa Ana MS4 Permit requirements. City staff receive storm water complaints directly by phone and email, and from the regional reporting hotline. City and contract staff work to immediately address and eliminate illegal discharges. Refer to LIP Section 4.
Development Planning (Prov E.3)															
DEV-1	Entire Jurisdiction	New and redevelopment of all land uses	For all development projects, administer a program to ensure implementation of source control BMPs to minimize pollutant generation at each project and implement LID BMPs to maintain or restore hydrology of the area, where applicable and feasible.	Both	X	X	X	X	X	X	X	X	X	Continuous	All development projects are required to implement minimum BMPs. The City of Menifee follows the development requirements outlined in the Santa Ana MS4 Permit. Refer to Local Implementation Plan (LIP) Section 6.
DEV-2	Entire Jurisdiction	New and redevelopment of all land uses	For Priority Development Projects, administer a program requiring implementation of structural BMPs to control pollutants and manage hydromodification. Includes confirmation of design, construction, and maintenance of structural BMPs.	Both	X	X	X	X	X	X	X	X	X	Continuous	All Priority Development Projects are required to implement and maintain post construction BMPs. The City of Menifee follows the development requirements outlined in the Santa Ana MS4 Permit. Priority Development Projects that require a Water Quality Management Plan (WQMP) must follow the guidance of the Santa Ana Watershed WQMP. Refer to LIP Section 6.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Construction Management (Prov E.4)															
CON-1	Entire Jurisdiction	Construction waste management	Administer a program to oversee implementation of BMPs during the construction phase of land development. Includes inspections at an appropriate frequency and enforcement of requirements. Menifee does not have any known agricultural land in the SMR WMA. Therefore, it is not anticipated that any construction projects will involve conversion of agricultural land.	Both		X		X	X			X	X	Continuous	All construction sites are required to implement minimum BMPs. Inspections are tracked to ensure that they meet the minimum inspection frequencies required by the Santa Ana MS4 Permit. **Frequencies:** High priority sites are inspected at least once monthly during the rainy season. Medium priority sites are inspected at least twice during the rainy season. Low priority sites are inspected at least once during the rainy season. All sites are inspected as-needed during the dry season. Refer to LIP Section 7.
Existing Development Management (Prov E.5)															
EXIST DEV-1	Entire Jurisdiction	Commercial - general, Commercial - nurseries, Industrial	Administer a program to require implementation of minimum BMPs for industrial and commercial development that are specific to the facility, area types, and pollutants generated, as appropriate. Includes inspection of existing development at appropriate frequencies.	Both	X	X		X	X	X	X	X	X	Continuous	All industrial and commercial facilities are required to implement minimum BMPs. Inspections are tracked to ensure that they meet the minimum inspection frequencies required by the Santa Ana MS4 Permit. **Frequencies:** High priority facilities are inspected at least once per year. Medium priority sites are inspected at least once every other year. Low priority sites are inspected at least once every five years (during a Permit term). Refer to LIP Section 8. Menifee does not have any known agricultural land within the Santa Margarita Watershed. However, if inspectors identify any facilities engaged in agricultural or livestock activities that are required to file for coverage under an agricultural conditional waiver program, these facilities will be reported to Regional Board staff.
EXIST DEV-2	Entire Jurisdiction	Industrial	Notify Regional Board of industrial businesses subject to the Industrial General Permit so that the businesses may obtain coverage as required.	Both	X	X		X	X	X	X	X	X	Continuous	The City of Menifee will share inspection results with Regional Board staff and notify of non-filers or potential noncompliance with other IGP requirements, especially requirements specifically related to discharges of nutrients. Refer to LIP Section 8

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
EXIST DEV-3	Entire Jurisdiction	Municipal	Administer a program to require implementation of minimum BMPs at municipal facilities. Includes inspection of facilities at appropriate frequencies.	Both	X	X		X	X	X	X	X	X	Continuous	All municipal facilities are required to implement minimum BMPs. Inspections are tracked to ensure that they meet the minimum inspection frequencies required by the Santa Ana MS4 Permit. **Frequency:** All fixed municipal facilities and field operations identified in Table 5-3 of the Drainage Area Management Plan (DAMP) are required to be inspected annually. The City also inspects its public parks annually to ensure that the parks are not a contributor to storm water pollution. Refer to LIP Section 5.
EXIST DEV-4	Entire JurisdictionCollaboration with RCFCWCD	Residential	Promote and encourage implementation of minimum BMPs at residential areas.	Both	X	X		X	X	X	X	X	X	Continuous	The City of Menifee participates in regional activities to facilitate the proper collection and management of used oil, toxic and hazardous materials, and other household wastes. The City also promotes the Riverside County Watershed Protection Program, which provides educational materials for landscaping and gardening and pet owners, among others. Refer to LIP Section 9.
EXIST DEV-5	Entire Jurisdiction	Residential - (Specifically Equestrian and Livestock Activities)	Require proper management of animal waste by residents to prevent transport of wastes and wash water offsite.	Both	X	X						X	X	Continuous	The City of Menifee has adopted a Manure Management and Disposal Ordinance (Order 2013-131U) to address the threat to water quality posed by the accumulation of manure on properties. The ordinance outlines best management practices and establishes regulations for the proper handling, temporary storage, collection, and disposal of manure in the City of Menifee. Refer to LIP Section 3.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
EXIST DEV-6	Entire Jurisdiction Collaboration with RWQCB	Streets within all land uses	Implement operation and maintenance activities (inspection and cleaning) for MS4 and related structures (catch basins, storm drain inlets, open channels, detention basins, etc.) for water quality improvement.	Both	X	X			X			X	X	Continuous	The City of Menifee inspects catch basins annually before the rainy season and cleans basins when accumulated materials are present. Large storm drain pipes, as well as open channels and detention basins in the City are owned and maintained by the Riverside County Flood Control and Water Conservation District. Refer to LIP Section 5.
EXIST DEV-7	Entire Jurisdiction Collaboration with County of Riverside Transportation Dept.	Streets within all land uses	Implement operation and maintenance activities for streets.	Both	X			X	X	X	X	X	X	Continuous	Street sweeping is done on selected routes twice per month by the County of Riverside. Refer to LIP Section 5.
Enforcement Response Plans (Prov E.6)															
ENF-1	Entire Jurisdiction	Illicit Discharges, Development, Construction, Industrial, Commercial, Municipal, Residential	Implement escalating enforcement responses to compel compliance with ordinances, permits, contracts, orders, and other requirements for ICID, development planning, construction management, industrial/commercial, municipal, and residential development (including residential equestrian and livestock activities)	Both	X	X		X	X	X	X	X	X	Continuous	The City has established the legal authority to require BMP implementation, including preventing illegal discharges, through the Stormwater Ordinance (Chapter 15.01 of the Municipal Code). When noncompliance is noted, the City initiates an enforcement process to bring about correction. Refer to LIP Section 3.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Public Education and Participation (Prov E.7)															
PUB ED-1	Entire Jurisdiction Collaboration with RCFCWCD	Industrial, Commercial, Municipal, and Residential	Implement a public education and participation program to promote and encourage development of programs, management practices, and behaviors that reduce the discharge of pollutants in storm water prioritized by high-risk behaviors, pollutants of concern, and target audiences.	Both	X	X		X	X	X	X	X	X	Continuous	Direct education is provided through interaction with the public during inspections, complaint response investigations, and plan review comments. The City educates businesses and residents about sources of pollutants, including waste management, erosion prevention (sediment), proper fertilizer use (nutrients), and discharge prevention, during inspections and complaint response investigations. Educational materials on a variety of storm water topics are available on the Riverside County Watershed Protection program website. This includes information related to residential gardening and overwatering prevention tips that can be shared with residents in the Santa Margarita Watershed. Refer to LIP Section 10 and DAMP Section 10 for details on the regional public outreach program.
PUB ED-2	Entire Jurisdiction Collaboration with RCFCWCD	Industrial, Commercial, Municipal, Residential, Illicit Discharges, Development, Construction.	Provide municipal staff training.	Both	X	X		X	X	X	X	X	X	Continuous	Staff are trained on BMP requirements and implementation. Target audiences include Engineering, Public Works, construction inspectors and plan reviewers. Training may be internal or provided by Riverside County Flood Control and Water Conservation District. Refer to LIP Section 11.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Optional Jurisdictional Strategies															
OPT-1	Target Area(s)	Residential	Develop and implement a residential inspections program. Areas covered would include mainly rural residential and some urban residential.	Both	X	X		X	X	X	X		X	FY18/19-Continuous	**Triggers:** The City plans to implement this strategy upon approval of the WQIP and will continue annual implementation provided the following trigger is met: 1) staff resources are identified and secured. **Approach:** The Santa Ana MS4 Permit does not require residential storm water inspections. However, since the majority of the City's 1.3 square miles within the Santa Margarita Watershed is rural residential, the City will develop and implement an annual residential drive-by inspection program to identify illicit connections, illegal discharges, and other potential pollutant discharges within residential areas in the Santa Margarita River Watershed. Inspectors will also look for evidence of improper BMP implementation related to manure management (see Strategy EXIST DEV-5) in rural residential areas with equestrian and livestock activities. The City will establish Standard Operating Procedures and develop an inspection checklist as part of the residential inspection program. **Funding:** Funding and resources have been secured for FY18. Funding for future fiscal years is contingent on annual budget approval by City Council. Funds anticipated to come out the general fund.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-2	Target Area(s)	Residential	Enhance public education and outreach for residents.	Both	X	X		X	X	X	X			Once triggered, as resources allow	**Triggers:** This strategy may be implemented at the City's discretion if the following triggers are met: 1) significant storm water deficiencies are observed during residential inspections in a given year, 2) it has been determined by City of Menifee staff through adaptive management that implementation is necessary, and 3) staff resources are identified and secured. **Approach:** Develop and implement a targeted outreach and education program for residents in the Santa Margarita Watershed based on the results of annual residential inspections. Educational topics will be based on issues identified during inspection (e.g. If equestrian washing were noted as an issue during inspection, educational materials targeting proper washing BMPs could be developed). Distribution methods and media type (i.e. online vs. print) to be determined based available resources and inspection staff input. **Funding:** Funding for future fiscal years is contingent on annual budget approval by City Council. Potential funding sources anticipated to be general fund and/or grant sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-3	Target Area(s)	Commercial - nurseries and animal facilities	Increase inspection frequency for highest nutrient pollutant potential businesses within the Santa Margarita Watershed.	Both	X	X		X	X	X	X			Once triggered, within 1 year (contingent upon timing of annual inventory prioritization)	**Triggers:** This strategy may be implemented at the City's discretion if the following triggers are met: 1) An interim goal has not been met, 2) it has been determined by City of Menifee staff through adaptive management that implementation is necessary, and 3) staff resources are identified and secured. **Approach:** Commercial non-agricultural animal facilities and commercial nurseries are generally assigned a medium priority, which translates to a stormwater inspection at least every other year. Under this strategy, if these businesses are identified as having high potential for contributing nutrients to the Santa Margarita Watershed, they would be elevated to high priority, increasing the minimum inspection frequency to once per year. **Funding:** Funding for future fiscal years is contingent on annual budget approval by City Council. Anticipated source would be the general fund.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-4	Target Area(s)Collaboration with County of Riverside Transportation Dept.	Open Space/Stream Restoration	Coordinate with Riverside County Transportation during review of an encroachment permit to support an integrated mitigation project.	Wet	X	X	X	X	X	X	X			Once triggered. Overall implementation timeline dependent on project schedule as determined by County of Riverside Transportation	**Triggers:** This strategy will be implemented if the following trigger is met: 1) Riverside County Transportation submits project application for encroachment permit to the City of Menifee. **Approach:** Riverside County Transportation is planning an integrated mitigation project which would result in the creation of over 1,500 linear feet of new intermittent channel and seasonal wetlands. The 75-acre site is located south of Scott Road and west of Briggs road in the County of Riverside. The project will preserve, restore and enhance the existing un-named creek (which is tributary to Warm Springs Creek), ephemeral drainages, and associated wetland habitats. The area is immediately outside of the City jurisdiction; however, the project will require infrastructure in the City of Menifee. Because of that, the City will work closely with Riverside County Transportation to facilitate the approval of an encroachment permit. **Funding:** Project funding to be secured by County of Riverside. Per County, the project is partially funded with CFD funds, with the remainder yet to be determined.

Table 4-7. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – City of Murrieta

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy		HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
				Dry Weather/ Wet Weather/ Both	Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)															
IDDE-1	Entire Jurisdiction	Residential, commercial, nurseries, industrial, parks and recreation, open space	Enhanced municipal training programs and curriculum targeting key field staff. Programs will focus on the water quality improvement plan, HPWQC, NNE requirements as related to illicit discharges and elimination of dry weather flows.	Dry Weather	X	X		X	X	X	X		X	Upon WQIP acceptance, FY 18-19	Public Works, CSD field staff and Code Enforcement will be provided enhanced municipal training. This training would also include training on the system used to record/track illicit discharges. GIS map to be developed and updated with illicit discharges database.
IDDE-3	Entire Jurisdiction	Residential, commercial, nurseries, industrial, parks and recreation, open space	Plot IDDE incidents in GIS to identify clusters where community outreach and workshops would be effective in eliminating dry weather flows.	Dry Weather	X	X		X	X	X	X		X	Upon WQIP acceptance, FY 19-20	Coordinate with GIS to create a layer that show IC/ID incidents based on information from reporting/tracking system.
Development Planning (Prov E.3)															
DEV-1	Entire Jurisdiction	Residential, commercial	Smart irrigation conditions of approval	Dry Weather	X	X		X		X	X	X	X	Ongoing	Condition PDPs to demonstrate that the irrigation controller and heads are set so irrigation runoff does not enter the street or MS4s.
DEV-2	Entire Jurisdiction	Residential, commercial	BMP Design Manual Training	Wet Weather	X	X		X		X	X		X	Upon WQIP acceptance, FY 17-18	Provide BMP Design Manual training to all applicable staff.
Construction Management (Prov E.4)															
CON-1	Entire Jurisdiction	Residential, commercial	Provide internal staff training related to construction storm water management	Dry and Wet Weather	X	X		X		X	X		X	Upon WQIP acceptance, FY 17-18	Internal staff to attend construction storm water management trainings.
Existing Development Management (Prov E.5)															
ED-6	Entire Jurisdiction	Residential, commercial, nurseries, industrial, parks and recreation, open space	Enhanced municipal training programs and curriculum targeting inspections staff. Programs will focus on the water quality improvement plan, HPWQC, NNE requirements as related to the inspections programs and specific nutrient issues.	Dry Weather	X	X		X	X	X	X		X	Upon WQIP acceptance, FY 18-19	Inspections staff will be provided enhanced municipal training. This training would also include training on the system used to record/track illicit discharges. GIS map to be developed and updated with illicit discharges database.
ED-3	Focus Areas Only	Commercial, industrial, parks and recreation, open space	Enhance commercial / industrial / municipal inspections programs to focus on irrigation systems.	Dry Weather	X	X		X		X	X			Upon WQIP acceptance, FY 20-21	Identify target areas through field screenings and annual inspections. Increase inspection frequencies as necessary.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
ED-4	Focus Areas Only	Residential	Enhance residential inspections programs to focus on over-irrigation.	Dry Weather	X	X		X		X	X			Upon WQIP acceptance, FY 20-21	Identify target areas through field screenings and annual inspections. Increase inspection frequencies as necessary.
ED-2	Focus Areas Only	Residential, commercial, nurseries	Increase inspection frequencies at facilities identified on Copermittee inventories to be sources of nutrients	Dry Weather	X	X		X	X	X	X			Upon WQIP acceptance, FY 21-22	Identify target areas through field screening and annual inspections. Increase inspection frequencies as necessary. If any sources of nutrients are identified, i.e. nurseries, inspections would be appropriately conducted.
ED-7	Focus Areas Only	Residential, commercial, nurseries	Enhanced enforcement program targeting identified, problematic, sources of nutrients	Dry Weather	X	X		X	X	X	X			Upon WQIP acceptance, FY 21-22	Identify problematic areas through field screening and annual inspections. Increase follow up efforts as necessary.
Enforcement Response Plans (Prov E.6)															
ERP-1	Entire Jurisdiction	Residential, commercial, industrial, nurseries	Implement escalating enforcement responses to compel compliance with statutes, ordinances, permits, contracts, orders, and other requirements for IDDE, development planning, construction management, and existing development in the Enforcement Response Plan.	Dry Weather	X	X		X		X	X	X	X	Ongoing	Escalating enforcement strategies will initially start with a Notice of Violation, written or verbal, a follow up, and if violator is not working towards compliance, the Administrative Citation process will begin increasing fines for non-compliance.
Public Education and Participation (Prov E.7)															
PubEd-2	Focus Areas Only	Residential	Enhanced outreach programs targeting homeowner's associations/residential communities.	Dry Weather	X	X		X	X	X	X			Upon WQIP acceptance, FY 22-23	Identify target areas amongst homeowner's associations/residential communities. Distribute targeted informational brochures/pamphlets.
Optional Jurisdictional															
OPT-1	Focus Areas Only	Residential	Water District Coordination - Coordination with Water Districts to pinpoint problem sources of dry weather flows.	Dry Weather	X	X		X		X	X			Upon WQIP acceptance and if triggered	This optional strategy may be triggered if 1) an interim dry weather goal has not been met; 2) it is determined by the City that this strategy would effectively address dry weather flows; and 3) available grant funding. Implementation of strategy would occur the following fiscal year after obtaining necessary approvals and procurement of funding.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy		HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
				Dry Weather/ Wet Weather/ Both	Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-2	Focus Areas Only	Residential	Water District Coordination - Coordination with Water Districts on inspection and enforcement efforts.	Dry Weather	X	X		X		X	X			Upon WQIP acceptance and if triggered	This optional strategy may be triggered if 1) an interim dry weather goal has not been met; 2) it is determined by the City that this strategy would effectively address dry weather flows; and 3) available grant funding. Implementation of strategy would occur the following fiscal year after obtaining necessary approvals and procurement of funding.
OPT-3	Entire Jurisdiction	Municipal, parks and recreation	Establish semiannual meetings among Engineering and Community Services District to evaluate opportunities for improving water quality at MS4s, streets, parking lots, parks and other landscaped areas.	Dry and Wet Weather	X	X		X	X	X	X			Upon WQIP acceptance and if triggered	This optional strategy may be triggered if 1) an interim dry weather goal has not been met; and 2) it is determined by the City that this strategy would effectively address dry weather flows. Implementation of strategy would occur 6 months after it has been determined that an interim dry weather goal has not been met.
OPT-4	Entire Jurisdiction	Residential, commercial, nurseries, industrial, parks and recreation, open space	Establish semiannual meetings to discuss potential ordinance changes.	Dry and Wet Weather	X	X	X	X	X	X	X			Upon WQIP acceptance and if triggered	This optional strategy may be triggered if 1) an interim dry weather goal has not been met; and 2) it is determined by the City that this strategy would effectively address dry weather flows. Implementation of strategy would occur 6 months after it has been determined that an interim dry weather goal has not been met.
OPT-5	Entire Jurisdiction	Municipal	Establish semiannual meetings among CIP staff to identify opportunities to rehabilitate channels or habitats.	Wet Weather	X	X	X	X						Upon WQIP acceptance and if triggered	This optional strategy may be triggered if 1) an interim dry weather goal has not been met; and 2) it is determined by the City that this strategy would effectively address dry weather flows. Implementation of strategy would occur 6 months after it has been determined that an interim dry weather goal has not been met.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Optional WMA Strategies															
OPT-6	Entire Jurisdiction	Residential	Partner with Water Districts to implement incentive program.	Dry Weather	X	X	X	X		X	X			Upon WQIP acceptance and if triggered	Optional WMA strategy may be triggered if: 1) an interim dry weather goal is not met; 2) it is determined by the City that this strategy would effectively address dry weather flows; and 3) available grant funding. Implementation of strategy would occur the following fiscal year after obtaining necessary approvals and receipt of grant funding.
OPT-7	Entire Jurisdiction	Residential	Regional inspector to inspect areas watershed-wide for anthropogenic sources of dry weather flows.	Dry Weather	X	X		X		X	X			Upon WQIP acceptance and if triggered	Optional WMA strategy may be triggered if: 1) an interim dry weather goal is not met; 2) it is determined by the City that this strategy would effectively address dry weather flows; and 3) available grant funding. Implementation of strategy would occur the following fiscal year after obtaining necessary approvals and receipt of grant funding.

Table 4-8. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – City of Temecula

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)															
IDDE-1	City of Temecula - Entire Jurisdiction	Commercial - general, Commercial - nurseries, Industrial, Residential (including OWTS), Municipal, Sanitary Sewer, Parks and recreation, Streets, Orchards/Vineyards and other agriculture discharging to the MS4.	Update ordinances to reflect current illicit discharge and connections requirements and strategies to reduce non-stormwater discharges to the MS4 during dry and wet weather.	Both	X	X	X	X	X	X	X	X	X	Once a Permit Term	This strategy will provide the city legal authority to enforce discharge prohibitions as required in the permit. The City of Temecula will have the resources in place to eliminate illicit discharges and improper disposal into the MS4, or otherwise require the discharger to apply for and obtain a separate NPDES permit. IDDE inspection frequencies will be concurrent with construction, business, existing development and other inspections and as reported by public and City staff.
IDDE-2	City of Temecula - Target Area(s)	Commercial - general, Commercial - nurseries, Industrial, Residential (including OWTS), Municipal, Sanitary Sewer, Parks, Streets, Landfills, Orchards/Vineyards and other agriculture discharging to the MS4.	Post signage adjacent to open channels providing information to report any observed illicit discharges. Signage will focus on sources of non-stormwater discharges such as illegal dumping and over-irrigation.	Both	X	X	X	X	X	X	X			FY 19-20, one time only	This strategy is expected to increase the number of illicit discharge and connections reported. The City of Temecula will have the resources in place to eliminate illicit discharges and improper disposal into the MS4, or otherwise require the discharger to apply for and obtain a separate NPDES permit. Signage will be inspected as part of existing development inspections.
IDDE-3	City of Temecula - Entire Jurisdiction, Receiving water; collaboration with the Police Department, resource agencies, Flood Control, Environmental Community	Homeless encampments are known to be located in areas such as Parks and recreation, Streets, Open Space, and Multiple Species Habitat Conservation Program areas.	Responsible Compassion for the Homeless Program will be implemented to address homeless problems throughout the City, thereby reducing their impacts on water quality through trash, illegal dumping, and direct discharge of human waste.	Both	X	X	X	X	X	X	X	X	X	Continuous	The City of Temecula directs homeless individuals to resources to seek housing which reduces the likelihood that homeless individuals will contribute to the loading of pollutants associated with the HPWQC and PWQCs. These areas are monitored continuously by 4 full time dedicated deputy sheriff assigned to support homeless outreach efforts.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Development Planning (Prov E.3)															
DEV-1	City of Temecula - Entire Jurisdiction	Commercial - general, Commercial - nurseries, Industrial, Residential, Municipal, Parks and Recreation, Streets, Orchards/Vineyards and other agriculture that is permitted through the City.	Modified Low Impact Development requirements for new and redevelopment to specifically address nutrients during dry and wet weather through increased use of disconnected impervious surfaces, on-site retention of dry weather flows, and treatment of stormwater prior to discharge.	Both	X	X	X	X		X	X			FY 18-19	The City of Temecula will review its Low Impact Development requirements for new and redevelopment and modify the requirements to promote attainment of the goals identified within this WQIP as part of its adaptive management program.
DEV-2	City of Temecula - Entire Jurisdiction	Commercial - general, Commercial - nurseries, Industrial, Residential, Municipal, Parks and Recreation, Streets, Orchards/Vineyards and other agriculture that is permitted through the City.	Amend BMP design manuals to address sources of HPWQCs and PWQCs on new and redevelopment projects (e.g., irrigation design standards, LID implementation) and conduct internal staff training on updated BMP design manual	Both	X	X	X	X	X	X	X			FY 19-20	The City of Temecula will review the BMP design manuals and amend the manuals as necessary to promote attainment of the goals identified within this WQIP. Staff will be trained annually to ensure proficiency with the elements of the amended BMP design manuals
Construction Management (Prov E.4)															
CON-1	City of Temecula - Entire Jurisdiction	Active construction sites.	Require implementation of BMPs that reduce the potential of HPWQC and PWQC loading, that are site specific and appropriate to the construction phase, year round.	Both	X	X	X	X	X	X	X	X	X	On-going	Implement as part of the JRMP Construction Management Program; ensure that sources of HPWQC/PWQCs have BMPs implemented year round (e.g., erosion/sediment control, materials storage, trash management).
CON-2	City of Temecula - Entire Jurisdiction, former agricultural lands	Active construction on parcels previously used for agriculture.	Where former agricultural lands are issued grading permits for development/ redevelopment, the sites will be deemed high priority for BMP implementation and inspection in accordance with the City's JRMP.	Both	X			X				X		On-going, As Applicable	Modify grading approval and construction site inspections process to ensure that former agricultural lands are deemed high priority, regardless of other factors (e.g., size, slope, proximity) and inspected accordingly. High priority sites are inspected twice per month from Oct 1 - Apr 30 and at least once in August or September each year.
CON-3	City of Temecula - Entire Jurisdiction	Active and inactive construction sites	Impose legal authority to ensure inventoried construction projects are in compliance with all requirements.	Both	X	X	X	X	X	X	X	X	X	On-going	Enforce stormwater, grading, and erosion control ordinances in accordance with the City's Enforcement Response Plan on all active and inactive construction sites through inspections and follow-up. Frequencies for both active and inactive construction site inspections vary based upon the assessed priority of the site as discussed in the City of Temecula JRMP.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Existing Development Management (Prov E.5)															
ED-1	City of Temecula - Entire Jurisdiction	Commercial, Industrial, Residential, OWTS, Municipal, Sanitary Sewer, Parks, Streets, Landfills	Enhanced municipal training programs and curriculum targeting inspections staff. Programs will focus on specific nutrient related activities that inspectors might encounter in the field such as non-stormwater flows and their sources (e.g., over-irrigation, illegal washing/dumping) and materials storage BMPs (e.g., coverage and containment) within existing development.	Dry	X			X		X				FY18-19	The City of Temecula will develop a curriculum that educates its inspection staff regarding the HPWQC and particular sources and areas of focus so as to reduce the potential loading from properties being inspected. Training will be conducted on an annual basis.
ED-2	City of Temecula - Target Area(s); collaboration with Rancho California Water District	Commercial, Industrial, Residential, Municipal, Parks	Install weather based irrigation controllers in municipal parks and promote incentive programs elsewhere (as available) to address sources of over-watering and irrigation runoff within existing development.	Dry	X	X	X	X		X	X		X	On-going for New Parks	The City of Temecula will install weather based irrigation controllers to reduce the potential for runoff and contact Rancho California Water District to discuss opportunities to provide incentives for their use elsewhere.
ED-3	City of Temecula - Entire Jurisdiction; collaboration with CR&R	Residential, Streets	Weekly street sweeping in residential areas to reduce pollutant buildup (e.g., organic debris, trash, metals) on streets and curb/gutter areas, thereby reducing transport of pollutants to the storm drain system via non-stormwater and stormwater flows.	Both	X	X		X	X	X		X	X	On-going	All residential streets are swept by the City's contractor the day following the trash service day. If trash service is provided on Friday, the streets are swept on Monday. Signs are posted asking residents to please refrain from parking on the residential streets on both trash collection and street sweeping days in order allow the City's contractor to provide efficient trash collection and street sweeping services.
ED-4	City of Temecula - Entire Jurisdiction	Agricultural	Modify City JRMP to include any Agricultural business operation as a high priority business inspection similar to industrial business. Report any Non-filing businesses to the Regional Board.	Both	X	X	X	X	X	X	X		X	Annual	This strategy will be incorporated into the City Business inspection component.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Enforcement Response Plans (Prov E.6)															
ERP-1	City of Temecula - Entire Jurisdiction	Construction Sites, New Development Projects, Redevelopment Projects, Existing Development Sites (Residential, Industrial, Commercial, Nurseries, Parks and Recreation, Orchards, Vineyards, Nurseries, horse ranches/ equestrian, other agriculture draining to the City's MS4)	Implement escalating enforcement responses to compel compliance with statutes, ordinances, permits, contracts, orders, and other requirements for IDDE, development planning, construction management, and existing development in the Enforcement Response Plan.	Both	X	X	X	X	X	X	X	X	X	On-going, As Needed	The City will enforce all applicable ordinances using a progressive enforcement approach as described in the City's Enforcement Response Plan
Public Education and Participation (Prov E.7)															
PUB-1	City of Temecula - Target Area(s)	Residential areas with Homeowners Associations (HOAs).	Enhanced outreach programs targeting homeowners associations to educate homeowners and HOAs about outdoor water usage, the effects of over-irrigation, and specific BMPs they can implement to reduce runoff from over-irrigation.	Both	X	X		X	X	X	X			FY18-19, Annual	The City of Temecula will review the literature and develop an enhanced outreach program for homeowners associations that utilizes the strategies that have been identified as most successful for this target audience on an annual basis.
PUB-2	City of Temecula - Target Area(s)	Commercial - general, Commercial - nurseries, Industrial, Residential, Municipal, Parks and recreation, Streets, Orchards/Vineyards and other agriculture discharging to the MS4.	Enhanced outreach materials focused on sources of nutrients (e.g., door hangers, pamphlets, other media). Outreach materials will focus on non-stormwater discharges to the storm drain system (e.g., septic system maintenance, equestrian facility BMPs, outdoor water usage, the effects of over-irrigation, and specific BMPs they can implement to reduce runoff from over-irrigation).	Dry	X			X		X				FY18-19, Annual	The City of Temecula will review the literature and develop enhanced outreach materials focused on sources of nutrients during dry weather that utilize the strategies that have been identified as most successful for this condition on an annual basis.
PUB-3	City of Temecula - Entire Jurisdiction	Agricultural	Notify agricultural business license holders within City Jurisdiction of requirement to enroll in the Regional Water Board Agricultural Order.	Both	X	X	X	X	X	X	X		X	Annual	This strategy will be incorporated into the City Business inspection component.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Optional Strategies (Prov B.3.b.(1)(b))															
Opt-1	At project site as further detailed within the project description and City of Temecula Capital Improvement Plan.	Municipal, Parks	Implement Parks Improvement Program that will provide landscaping, irrigation, and on-site drainage improvements that will reduce the potential for pollutant discharges (e.g., irrigation runoff, fertilizer) from municipal parks.	Both	X	X		X		X	X			Upon being triggered and all funds and/or resources being secured (approximately two years from determination that trigger has been met); One Time	This project would facilitate rehabilitation and improvement projects at various City parks. The rehabilitation and improvement projects could include, but are not limited to, landscaping and irrigation system efficiency upgrades and on-site drainage improvements to reduce the loading of nutrients and other pollutants contributing to PWQCs associated with irrigation and stormwater runoff. [1][2]
Opt-2	At project site as further detailed within the project description and City of Temecula Capital Improvement Plan; Coordination with Riverside County Flood Control and Water Conservation District	Municipal, Parks	Flood control channel repair and rehabilitation to prevent erosion and the transport of sediment-bound pollutants.	Both	X		X	X						Upon being triggered and all funds and/or resources being secured (approximately two years from determination that trigger has been met); One Time	This project repairs and reinforces the earth and berms between specific park sites and flood control channels and rehabilitates the banks to support vegetation and prevent further erosion into the park sites and the transport of sediment-bound nutrients and other pollutants contributing to PWQCs. [1][2]

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Opt-3	To be determined based on information obtained from the Monitoring and Assessment Program; Coordination with Eastern Municipal	Commercial - general, Commercial - nurseries, Industrial, Residential, Municipal, Parks and recreation, Streets, Orchards/Vineyards and other agriculture discharging to the MS4.	Implement dry weather infiltration, diversion to sanitary sewer, to eliminate non-stormwater discharges to the MS4.	Dry	X	X	X	X	X	X	X			Upon being triggered and all funds and/or resources being secured (approximately two to five years from determination that trigger has been met); One Time	This strategy would address persistent dry weather flow in outfalls due to over-irrigation. Outfalls which are persistently flowing due to over-irrigation and which contribute significantly high nutrient loads would be evaluated for potential dry weather infiltration or diversion to sanitary sewer. [1][3]

[1] Implementation of these strategies may be triggered at the City of Temecula's discretion or if (1) persistent dry weather flows are identified; and (2) an interim goal has not been met; or it is determined that implementation is necessary to meet future goals; and (3) the project would help to reduce nutrient loading to receiving waters under dry or wet conditions; and (4) all necessary resources and permits have been secured for the project. Once triggered, it is estimated that it would take approximately two years to procure resources, proceed with engineering, landscape design, and construction to implement the strategy. Because implementation would be within City parks, environmental permitting would not be necessary.

[2] The funding-sources that must be secured to implement this optional strategy are: capital dollars identified in the approved CIP budget (funded through parks and/or drainage fees); staff time for project management and construction (funded through the general fund and/or development fees); budget for operations and maintenance of constructed BMPs (funded through the drainage fees and/or general fund). Once triggered, it is estimated that it would take approximately two years to procure resources, proceed with engineering/design, secure environmental permits, and proceed with construction necessary to implement the strategy.

[3] Funds and/or resources that must be secured to implement this optional strategy are the following: 1) In-field evaluation of suitable sites for infiltration, diversion to sanitary sewer, or treatment BMPs (funded through drainage fees and/or general fund); 2) Evaluation of feasibility (funded through drainage fees and/or general fund); 3) Engineering design plans (funded through drainage fees and/or general fund); 4) Capital Improvement Program funding secured to support 5 - 7 (through drainage fees or another fee supported funding mechanism); 5) Land acquisition and/or private-public partnership agreements (as necessary); 5) Construction contract bid/award; 6) Project construction; 7) Adequate resources for facility operation and maintenance. Once triggered, it is estimated that it would take two - five years to procure resources, proceed with engineering and design work, secure necessary environmental permits, and proceed with construction. Timing will depend on location, scope of the project, and environmental impacts.

The City of Temecula has included a summary of its land uses in chapter 3 table 3-1. Please note the City does not have any land uses zoned for agricultural. However agricultural operations are allowed on all residentially zoned land uses. All commercially operated agricultural operations within the city require a business license and the city uniquely identifies these in its business license inventory. There are currently no commercially operated vineyards or orchards within City limits. "Temecula Wine Country" is located outside Temecula City Limits.

Table 4-9. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – City of Wildomar

(Background: The City of Wildomar covers an area of approximately 24 square miles. The City is primarily located within the Santa Margarita River Watershed. About 33% of the City extends into the Santa Ana River Watershed. Low Density and Medium Density residential land uses predominantly characterize the City of Wildomar's current landscape. Many of the roads within the City are unimproved (i.e. dirt roads), partially improved (i.e. developed on one side), or are paved but do not have curb or gutter. More recently developed areas within the City do have full street improvements and drainage conveyance systems. As of 2015, the City's population was estimated to be 45% of the total expected population.).

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy		HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
				Dry Weather/ Wet Weather/ Both	Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)															
IDDE-1	City of Wildomar: - Entire Jurisdiction	Residential Commercial Industrial Parks and Recreation Horse Ranches/Equestrian Nurseries Other Agricultural	Assess IDDE incidents to identify clusters, if any, where targeted efforts may be effective in eliminating dry weather flows.	Dry	X	X	X	X	X	X			X	Continuous	Assess clusters to determine if there are target areas which require special attention, education, enforcement, or any additional/specific resources or targeted follow-up.
IDDE-2	City of Wildomar: - Entire Jurisdiction	Residential Commercial Industrial Parks and Recreation Horse Ranches/Equestrian Nurseries Other Agricultural	Update ordinances to reflect current illicit discharge and connections requirements and strategies.	Dry	X	X	X	X	X	X			X	Each Permit Term	
IDDE-3	City of Wildomar: - Entire Jurisdiction	Residential Commercial Industrial Parks and Recreation Horse Ranches/Equestrian Nurseries Other Agricultural	Utilize service request forms to improve internal and external reporting of IDDE incidents, to help staff more efficiently identify, report, and respond to IDDE incidents.	Dry	X	X	X	X	X	X			X	Continuous	
Development Planning (Prov E.3)															
DEV-1	City of Wildomar: - Entire Jurisdiction	Residential Commercial	Smart Irrigation Conditions of Approval	Dry	X	X	X	X	X	X		X	X	Ongoing	City Council has adopted the WATER EFFICIENT/CONSERVATION LANDSCAPE STANDARDS MANUAL. Items required in the manual are verified during development plan review and during inspections for projects which require landscape plans.
DEV-2	City of Wildomar: - Entire Jurisdiction	Residential Commercial	Revised post-construction guidelines to eliminate potential dry weather discharges from new and redevelopment	Dry	X	X	X	X	X	X	X		X	Continuous	Update plan review guidelines to require that, where feasible, areas of a site which may contribute to potential dry weather discharges are captured and directed to a treatment BMP to eliminate dry weather flows and potential nutrient loading (and other pollutants) from being transmitted downstream. Condition new projects accordingly and incorporate guidelines into Development Plan Check Guidelines.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy		HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
				Dry Weather/ Wet Weather/ Both	Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
DEV-3	City of Wildomar: - Entire Jurisdiction	Residential Commercial Industrial	Amend BMP design manuals to address priority sources and conduct internal staff training on updated BMP design manual	Both	X	X	X			X			X	Each Permit Term	Complete update through cooperation with other SMR Copermittees.
DEV-4	City of Wildomar: - Entire Jurisdiction	Commercial Residential	Require new development projects to develop and submit a Storm Water Quality Training Materials for employees. Require new development projects with CC&Rs to address stormwater pollution prevention practices.	Dry	X	X	X	X	X	X		X	X	Ongoing	Condition commercial development projects to require the development of Storm Water Quality Training Materials for employees to ensure that employees of new businesses are educated regarding stormwater pollution prevention and thereby reduce the potential for non-stormwater discharges. For all development projects requiring CC&Rs, require that the CC&Rs address stormwater pollution prevention requirements and practices. Require documentation (e.g. Employee Training Materials, CC&Rs, etc...) as applicable to each project to be submitted for review and for file, recordation, etc... prior to certificate of occupancy. Comment on documentation, as necessary, to ensure that the materials adequately target the applicable post-development activities. Education may target different sources by helping to reduce or eliminate unpermitted non-stormwater management discharges and the potential for nutrients and other pollutants to be transported through non-stormwater discharges.
DEV-5	City of Wildomar: - Entire Jurisdiction	Construction	Require Delineation of Jurisdictional Areas on Development Plans and Require Enhanced Sediment Control BMPs to be Shown Adjacent to Jurisdictional Areas on Development Plans	Both	X		X		X			X	X	Ongoing	Require all development projects to delineate and label jurisdictional areas on or immediately adjacent to the project site on grading or improvement plans and to add a note to the plans requiring delineation of jurisdictional areas on the project site in the field. Also require the plans to identify enhanced Sediment Control BMPs in locations adjacent to jurisdictional areas. Delineation of jurisdictional areas is intended to help reduce unintended construction impacts within these areas and protect and preserve physical habitats, reduce the amount of construction debris that may be deposited in these areas, and by reducing the potential for soil disturbance reduce the potential for nutrients to be transported downstream by sediment. Additional sediment controls adjacent to jurisdictional areas is also intended to limit the potential for nutrients to be transported downstream by sediment.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy		HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
				Dry Weather/ Wet Weather/ Both	Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
DEV-6	City of Wildomar: - Entire Jurisdiction	Streets Residential	Provide Street Sweeping Services for New Streets	Both	X	X	X	X	X	X		X	X	Ongoing	Require all new private development projects to annex into the Community Facilities District (CFD). CFD services will typically include street sweeping for newly developed streets (where applicable) that will be publicly maintained. Street sweeping can help eliminate sediment and other pollutants which may be transported downstream and which may transport nutrients downstream.
Construction Management (Prov E.4)															
CON-1	City of Wildomar: - Entire Jurisdiction	Construction Nurseries Other Agriculture	Implement, or require the implementation of, enhanced construction BMPs on specific projects.	Both	X	X	X	X	X	X			X	Continuous	Implement, or require the implementation of, enhanced construction BMPs on projects with applicable permit activities that have an historical land use normally associated with higher levels of nutrients than other land uses (e.g. project sites with an historical agricultural land use, project sites with known septic systems currently or previously installed onsite, etc...) to reduce the potential for nutrient rich soils to discharge from the project site during construction either by non-stormwater or stormwater related discharges.
CON-2	City of Wildomar: - Entire Jurisdiction	Construction	Provide enhanced focus on specific items during construction inspections.	Both	X	X	X		X				X	Per JRMP	Provide enhanced focus on landscape material storage BMPs during NPDES construction inspections to reduce the potential for materials with nutrients to leave the project site, either by non-stormwater or stormwater related discharges.
CON-3	City of Wildomar: - Entire Jurisdiction	Construction	Require Delineation of Jurisdictional Areas on Project Sites and Require Enhanced Sediment Control BMPs Adjacent to Jurisdictional Areas	Both	X		X		X			X	X	Ongoing	Require all development projects to have all onsite jurisdictional areas delineated prior to or by the pre-grading meeting. Require the continued delineation of such areas throughout the duration of construction, as applicable to each project. Ensure that jurisdictional areas are clearly identified in the field at pre-grading meetings and during grading inspections. Require development projects to implement enhanced Sediment Control BMPs in locations that are adjacent to jurisdictional areas. Delineation of jurisdictional areas is intended to help reduce unintended construction impacts within these areas and protect and preserve physical habitats, reduce the amount of construction debris that may be deposited in these areas, and by reducing the potential for soil disturbance reduce the potential for nutrients to be transported downstream by sediment. Additional sediment controls adjacent to jurisdictional areas is also intended to limit the potential for nutrients to be transported downstream by sediment.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
Existing Development Management (Prov E.5)															
ED-1	City of Wildomar: - Entire Jurisdiction	Municipal (Parks, Cemetery, Fire Station) Streets Illicit Discharges	Enhanced municipal training programs and curriculum targeting key field staff. Programs will focus on the water quality improvement plan, HPWQCs, NNE requirements as related to illicit discharges and elimination of dry weather flows.	Dry	X	X	X	X	X	X			X	Per JRMP	Complete training through cooperation with SMR Copermittees. Conduct additional internal training as necessary.
ED-2	City of Wildomar: - Entire Jurisdiction	Illicit Discharges from Over Irrigation	Install weather based irrigation controllers in public landscaped areas.	Dry	X	X	X	X	X	X		X	X	Ongoing	Public landscaped areas maintained by City maintenance districts have weather based controllers installed which help reduce the potential for over-irrigation and irrigation runoff.
ED-3	City of Wildomar: - Entire Jurisdiction	Illicit Discharges from Failing Septic Systems	Address failed septic systems that are discharging effluent to the ground surface.	Both	X	X	X			X	X	X	X	Ongoing	Coordinate with property owners through various City Departments and potentially coordinate with other agencies to eliminate unpermitted surface discharges from septic systems and to the extent possible, encourage property owners to repair/replace the failing septic system(s).
ED-4	City of Wildomar: - Entire Jurisdiction	Other Agricultural	Report potential Agricultural Permit Non-Filers to the Regional Board.	Both	X	X	X			X			X	Continuous	When the City is made aware of an agricultural operation that appears to require coverage under the Regional Board's Agricultural Order, notify the Regional Board.
ED-5	City of Wildomar: - Entire Jurisdiction	Residential Commercial Industrial Parks and Recreation Streets	Clean out catch basins.	Both	X	X	X	X	X	X		X	X	Continuous	Perform scheduled clean-out activities of publicly maintained catch basins to eliminate accumulated sediment, debris, and trash. Catch basin clean-out activities can help eliminate pollutants which may be transported downstream and which may transport nutrients downstream.
Enforcement Response Plans (Prov E.6)															
ERP-1	City of Wildomar: - Entire Jurisdiction	Residential Commercial	Implement escalating enforcement responses to compel compliance with statutes, ordinances, permits, contracts, orders, and other requirements for IDDE, development planning, construction management, and existing development in the Enforcement Response Plan.	Dry	X	X	X	X	X	X		X	X	Ongoing	Implement the ERP as described in the JRMP.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
Public Education and Participation (Prov E.7)															
PubEd-1	City of Wildomar: - Entire Jurisdiction	Nurseries	Enhanced outreach programs targeting nurseries	Both	X	X	X	X	X	X			X	Annually	Identify nurseries (a potential source of nutrients) located within City limits using City's Business Registration Database. Mail Targeted Public Education Materials to registered nurseries to help reduce the potential for pollutants (including nutrients) to be present in stormwater discharges. Complete Commercial Inspections for registered nurseries. Repeat process annually prior to each rainy season.
PubEd-2	City of Wildomar: - Entire Jurisdiction	Horse Ranches/Equestrian Residential	Enhanced outreach programs targeting animal facilities	Both	X	X	X	X	X	X			X	Continuous	Provide focused educational materials to property owners with livestock/equestrian operations regarding Best Management Practices to reduce the potential for non-stormwater discharges and to reduce the potential for pollutants (including nutrients) to be present in stormwater discharges.
PubEd-3	City of Wildomar: - Entire Jurisdiction	Commercial Residential Industrial Nurseries	Public Education for businesses and residents.	Both	X	X	X	X	X	X			X	Continuous	Provide targeted educational materials for businesses as identified in JRMP. Provide targeted stormwater pollution prevention information to all City based businesses, even if not required in JRMP (e.g. over-irrigation handouts to home-based businesses, septic system maintenance handouts to home-based business with septic systems, landscape maintenance handouts to home-based businesses, etc...) to reduce the potential for non-stormwater discharges which may contain nutrients and to reduce the potential for pollutants (including nutrients) to be present in stormwater discharges. Potentially provide contact information handout to business registration applicants which may include contact information for waste haulers, water districts, City, etc...) as well as general stormwater pollution prevention information. (NOTE: This item may require additional coordination and resources before it is determined that it can be implemented.) Place stormwater pollution prevention educational materials at City Front Counter for residents/developers/contractors/businesses. Include Storm Water related message in applicable Email Signatures.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
Optional Strategies															
OPT-1	City of Wildomar: - Target Areas identified Through Cooperation with the Water Districts	Residential Commercial	Coordination with Water Districts to pinpoint and address problem sources of dry weather flows; potential implementation actions could include rebate/incentive programs, irrigation retrofits, or other programs as appropriate and effective.	Dry	X	X	X	X	X	X				As Triggered: Within six (6) months of trigger, establish coordination meeting with Water Districts to proceed with strategy.	Implemented starting in the following fiscal year after triggered. Implementation of this strategy may be triggered if (1) persistent dry weather flows are identified; and (2) an interim dry weather goal has not been met; or it is determined that implementation is necessary to meet future goals; and (3) it is determined that coordination with a water district would be an effective strategy to address the source(s) of the identified dry weather flow. Grant Funding for either the City or the Water District(s) would likely need to be secured for incentive programs.
OPT-2	City of Wildomar: - SMR Region	Open Space Residential Commercial Industrial Parks and Recreation Horse Ranches/Equestrian Nurseries Other Agricultural	Consider and Prioritize, where possible, Multi-Benefit Master Drainage Plan Projects that have both Flood Control and Channel or Habitat Rehabilitation Benefits	Both	X		X		X					As Triggered: Within six (6) months of trigger, establish internal coordination meeting with Public Works Staff to discuss re-prioritization process for Master Drainage Plan Projects.	Implemented starting in the following fiscal year after triggered. Implementation of this strategy may be triggered if (1) persistent dry weather flows are identified; and (2) an interim dry weather goal has not been met; or it is determined that implementation is necessary to meet future goals; and (3) it is determined that prioritizing such multi-benefit projects would be an effective strategy to address the High Priority Water Quality Condition. If determined to be an effective strategy, funding for planning of such projects would be contingent on Area Drainage Plan Funding, Master Drainage Plan Funding, and any additional funds needed in excess of these two sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2017	FY2018	Future Fiscal Years	
OPT-3	City of Wildomar: - Entire Jurisdiction	Streets	Enhancements and/or adjustments to street sweeping practices, frequencies, and routes, as determined by jurisdiction.	Both	X	X	X	X	X	X				As Triggered: Within six (6) months of trigger, establish coordination meeting to discuss enhancement and adjustment of street sweeping and procedure to move forward.	Enhance existing street sweeping by assessing deficiencies on existing routes and making applicable modifications. Work with waste haulers to increase street sweeping to include City Arterial Streets and to provide litter pass services in areas with known trash accumulation to reduce pollutants which may be transported downstream by non-stormwater or stormwater discharges. Implemented starting in the following fiscal year after triggered. Implementation of this strategy may be triggered if (1) persistent dry weather flows are identified; and (2) an interim dry weather goal has not been met; or it is determined that implementation is necessary to meet future goals; and (3) it is determined that enhancements or adjustments to street sweeping would be an effective strategy to address the High Priority Water Quality Condition; and (4) implementation of this strategy is supported by cooperation with City waste haulers and legislative approval. Funding for enhancements and adjustments to street sweeping may involve increased waste hauling fees and City Council approval. Other enhancements may involve funding from the General Fund.
Optional WMAA Strategies															
The City of Wildomar will implement Optional WMA Strategies through cooperative agreements with the Santa Margarita River Copermittees. The Optional WMA Strategies that will be implemented are identified in the Riverside County Flood Control and Water Conservation District (RCFCWCD) WQIP Strategy Table. Please refer to the RCFCWCD WQIP "Optional WMA Strategies and Schedules" in Table 4-11 (Section 4.2) of the WQIP for details.															

Definitions:

Ongoing	- A strategy that the City currently implements (entirely or to some extent) and will continue to implement throughout WQIP implementation. Implementation will occur as triggered and is not limited to a specific frequency. See Specific Strategy Descriptions for events triggering implementation of this type of strategy.
Continuous	- A strategy that the City will begin implementing upon WQIP acceptance and will continue to implement throughout WQIP implementation. Strategy implementation will occur as required or triggered and is not limited to a specific frequency. See Specific Strategy Descriptions for events triggering implementation of this type of strategy.
Per JRMP	- A strategy that will be implemented based on a schedule or frequency that is identified in the City's Jurisdictional Runoff Management Plan.
Each Permit Term	- A strategy that will be implemented once per permit term, at a minimum.
Annually	- A strategy that will be implemented once per year, at a minimum.

Table 4-10. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – Riverside County

(Note: The following is the County of Riverside's WQIP strategies table. Specific focus is given to Nutrient source Target Areas (i.e. Agriculture (nurseries, equestrian and other livestock operations) and Residential Uses), then source areas of the other Priority Water Quality Pollutants. As part of the iterative adaptive management process, these strategies will be reviewed as part of the WQIP annual reporting analysis. If interim goals are not met, the strategies may change. Implementation of new strategies would be subject to funding, consistency with the General Plan and/or other regulatory requirements, and securing the necessary resources (e.g., staffing, partnerships, etc.).

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)												
1	County of Riverside	Illicit Discharge and Illegal Connections County-wide	Utilize municipal personnel and contractors to identify and report Illicit Connections and Discharges (with emphasis on over-irrigation).	✓	✓	✓	✓	✓	✓	✓	Continuous*	Utilize MS4 GIS mapping to focus these efforts for Nutrient Loading Land Uses including Residential and Agricultural as well as providing focused training to field staff/contractors. Identify areas through GIS analysis that need particular attention such as increased surveying and public education.
2	County of Riverside	Illicit Discharge and Illegal Connections County-wide	Develop a reporting mechanism for incidental observations of IC/ID by County staff field personnel.	✓	✓	✓	✓	✓	✓	✓	Continuous	Provide County field staff with IC/ID field forms with emphasis in locating sources of dry weather flows from Residential and Agricultural land uses. These forms are to be submitted to the County NPDES Administrator to initiate investigations, tracking and resolution. Follow up training will provide updates on the success of this Program and help identify additional strategies that could be incorporated.
3	County of Riverside	Illicit Discharge and Illegal Connections County-wide	Develop a procedure to map IC/ID cases in GIS to assist in ongoing identification of IC/ID target areas.	✓	✓	✓	✓	✓	✓	✓	Upon WQIP Approval	Field forms, as described above, shall be submitted to Transportation GIS to map specific IC/ID locations involving PWQP's, with emphasis on Nutrient sources. Scheduling inspections of IC/ID observations in Nutrient Loading Land Use Sources will be given priority.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
4	County of Riverside	Illicit Discharge and Illegal Connections County-wide	Conduct IC/ID - IDDE focused training for County Department field staff.	✓	✓	✓	✓	✓	✓	✓	Annually	Can be expedited through a "Train the Trainer Program" to disseminate training to County employees who work in the field. Emphasis will be given to identification and resolution of Nutrient and other PWQP land use sources and activities that are known to cause erosion and dry weather flows (such as agricultural activities).
5	County of Riverside	Illicit Discharge from Septic System Failures	Respond, educate and require mitigation on septic system failures where observed. Coordinate investigations with Environmental Health (County Regulatory Agency for Septic Systems). Focus on elimination of nutrient loading from phosphorus sources and bacteria loading to MS4 from septic failure. Educate property owners on proper septic maintenance and the importance of eliminating discharges to the MS4.	✓	✓	✓	✓	✓	✓	✓	Continuous	
6	County of Riverside	Illicit Discharge Detection and Elimination	Implement practices and procedures to address accidental spills (with emphasis on identifying Nutrient and other PWQP sources) with the potential to enter the storm drain system. Implement employee spill notification/reporting focused training County-wide.	✓	✓	✓	✓		✓	✓	Continuous	Can be expedited through a "Train the Trainer Program" to disseminate training to County field staff. Training shall focus on importance on identifying and resolving the sources of Nutrient and other PWQP loading to our Receiving Waters.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
New Development and Redevelopment Planning (Prov E.3)												
1	County of Riverside	New and Redevelopment of all Land Uses	Update BMP Design Manual procedures to specify storm water requirements applicable to development and redevelopment projects, identify and design appropriate BMPs, establish maintenance criteria, and establish alternative compliance options. Specific consideration to BMP implementation will be given to reducing/eliminating Nutrient and other PWQP loading to the MS4 and receiving waters.	✓	✓	✓	✓	✓		✓	Each Permit Term or as deemed necessary	
2	County of Riverside	New and Redevelopment of all Land Uses	Conduct training on the updated BMP Manual.	✓	✓	✓	✓	✓		✓	Continuous. Continue to require Annual Training to appropriate staff identified in the JRMP.	Training shall incorporate BMP implementation emphasis for Residential and Agricultural land uses to reduce/eliminate erosion and Nutrient and other PWQP loading to MS4 and receiving waters.
3	County of Riverside	New and Redevelopment of all Land Uses	Prepare drought tolerant Guidelines and Standards for new development and BMP retrofits (e.g. water smart irrigation controllers, turf replacements programs, residential landscape evaluation program).	✓	✓	✓	✓		✓	✓	Continuous or as deemed necessary	Landscape Ordinance and Educational Brochures provide guidelines that describe the importance of eliminating over irrigation, specifically for Residential and Agricultural land uses. Additional new guidelines will be developed to describe why these land uses are of particular concern (i.e., Nutrient and other PWQP loading to MS4 and receiving waters).
4	County of Riverside	County Capital Improvement Projects	Develop a NPDES DATA FORM for Design Teams to identify project-related NPDES data to facilitate: identification of HPWQC and PWQP sources, analyze HPWQC and PWQP source reduction in CEQA/NEPA document, and design of post-construction BMPs to address HPWQC and PWQPs loading reduction and hydromodification.	✓	✓	✓	✓	✓		✓	Upon WQIP Approval	Update form template as needed. Form shall provide footnote describing types of land uses (e.g., Residential and Agricultural) and activities (i.e., on-going grading, tilling, excavation, fertilizer use, etc.) that require particular attention to post-construction BMP implementation.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
5	County of Riverside	New and Redevelopment of all Land Uses	Update County codes, ordinances, and landscape design standards consistent with the permit, including but not limited to prohibition of over irrigation; and the updated BMP Manual.	✓	✓	✓	✓	✓	✓	✓	Upon WQIP Approval	Implement upon obtaining internal and Board of Supervisors' approvals.
Construction Management (Prov E.4)												
1	County of Riverside	Construction Erosion and Sediment Controls; and Waste Management	Require implementation of enhanced BMPs that reduce the potential of HPWQC and PWQP loading, and that are specific to the grading phase, year round.	✓	✓	✓	✓	✓		✓	Continuous	Could potentially be achieved through liquidated damages provisions in Capital Improvement Projects construction contracts
2	County of Riverside	Construction Erosion and Sediment Controls; and Waste Management	Make updates to County ordinances related to construction; reference to existing grading ordinance and requirement to implement enhanced BMPs to mitigate erosion and dry weather flows to MS4 and receiving waters in the SMR.	✓	✓	✓	✓	✓	✓	✓	As deemed necessary	
3	County of Riverside	Construction Erosion and Sediment Controls; and Waste Management	Ensure grading activities are classified as HIGH priority if land is surrounded by or was previously used for agricultural operations.	✓	✓	✓	✓	✓	✓	✓	Upon WQIP Approval, then Continuous	This Strategy is to prevent discharge of sediment with high levels of Nutrients and other PWQP's.
Existing Development (Prov E.5)												
1	County of Riverside	Existing and New Businesses	Enhance the Business Registration Program by educating owners on Nutrient and other PWQP source reduction.	✓	✓	✓	✓	✓	✓	✓	Continuous	Handout appropriate educational brochures to business owners.
2	County of Riverside	MS4 Sources	Implement a prioritized schedule of operation and maintenance activities for the storm water conveyance system draining Nutrient and PWQP source land uses (e.g. Residential and Agricultural).	✓	✓	✓	✓	✓	✓	✓	Continuous	

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
3	County of Riverside	Commercial, Industrial Residential, Agricultural and Municipal Land Uses	Require implementation of BMPs to address application, storage, and disposal of pesticides, herbicides, and fertilizers on commercial, industrial, agricultural (e.g., large commercial nurseries), residential, and municipal properties. Includes education, verifying permits and certifications.		✓	✓		✓		✓	Continuous	
4	County of Riverside	Commercial, Industrial Residential, Agricultural and Municipal Land Uses	Conduct inspections of inventoried existing development (including residential and agricultural land uses) to ensure BMPs are being implemented to reduce the potential of HPWQC and PWQP loading.	✓	✓	✓	✓		✓	✓	Continuous	
Enforcement (Prov E.6)												
1	County of Riverside	Existing Development	Enforce escalating legal authority established for all inventoried existing development, including residential and agricultural, to conserve water and eliminate dry weather flows. Verbal warnings shall be tracked along with written escalating enforcement.	✓	✓	✓	✓	✓	✓	✓	Continuous	
2	County of Riverside	New and Redevelopment of all Land Uses	Impose legal authority to ensure all development and redevelopment projects (with emphasis on residential, park and agricultural projects) are in compliance with all post construction requirements specifically as they pertain to erosion and dry weather flow prohibitions.	✓	✓	✓	✓	✓	✓	✓	Continuous	
3	County of Riverside	Illicit Discharge Detection and Elimination	Implement escalating enforcement responses to compel compliance with statutes, ordinances, permits, contracts, orders, and other requirements for IDDE, development planning, construction management, and existing development in the Enforcement Response Plan. Escalating enforcement strategies will initially start with education and verbal warnings and escalate to cease and	✓	✓	✓	✓	✓	✓	✓	Upon WQIP approval	Evaluate current escalating enforcement strategies and refine to specifically address the elimination of nutrient discharges and priority water quality pollutants (i.e., bacteria, metals, sediment and trash).

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
			desist orders to taking legal actions as necessary. All enforcement actions shall be tracked in a database.									
4	County of Riverside	Unpermitted Agricultural Operations	Report suspected agriculture operation "non-filers" to the Regional Board promptly. Maintain database of reported "non-filers".	✓	✓	✓	✓	✓	✓	✓	Continuous	Observations by field staff should report incidents to Code Enforcement for tracking purposes and the County NPDES Administrator for reporting to the Regional Board.
Public Education (Prov E.7)												
1	County of Riverside	Municipal Parks	Implement pet waste management outreach in County Parks for resident pet owners.	✓	✓		✓	✓		✓	Continuous	
2	County of Riverside	Residential/ Commercial/ Municipal	Implement a public education and participation program to promote and encourage development of programs, management practices and behaviors that reduce the discharge of HPWQC and other PWQPs (specifically for Residential and Agricultural land uses).	✓	✓	✓	✓	✓	✓	✓	Continuous	Coordinate efforts with RCFC&WCD, County Departments and partnering agencies such as Water and School Districts.
3	County of Riverside	Residential/ Commercial/ Municipal	Stock public County counters at Riverside County offices with Pollution Prevention Public Education brochures. Brochures should highlight the importance of proper fertilizer use/application and over irrigation. Other brochures should include emphasis on proper septic maintenance and other good practices to prevent nutrient and other PWQP loading to the MS4 and receiving waters, Provide brochures to other agencies for their public counters as well (e.g., School Administration Buildings).	✓	✓	✓	✓	✓	✓	✓	Continuous	

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
4	County of Riverside	Residential/ Commercial/ Municipal	Facilitate public reporting, through outreach and public education, of Illicit Connections and Illicit Discharges, including over-irrigation.	✓	✓	✓	✓	✓	✓	✓	Continuous	Evaluate current reporting mechanisms including social media, hotlines, and websites with this strategy. Implement additional outreach efforts in Target Areas if current Jurisdictional Strategies under perform. Measure effectiveness through Outfall discharge monitoring results. Coordinate public education outreach efforts with the Riverside County Flood Control and Water Conservation District (RCFC&WCD) Public Education Unit for support. Funding is provided through the Implementation Agreement between the County and RCFC&WCD. Implementation schedule will coincide with RCFC& WCD outreach efforts for the current fiscal year.

Optional Jurisdictional Strategies												
												Triggers:
1	Warm Springs Creek/ County of Riverside	Rural Residential/Agricultural Land Uses	Construct and manage the Integrated Mitigated Project This project will result in the creation of over 1,500 linear feet of new intermittent channel and seasonal wetlands. The 75-acre site is located south of Scott Road and west of Briggs road in the County of Riverside. The project will preserve, restore and enhance the existing un-named creek (which is tributary to Warm Springs Creek), ephemeral drainages, and associated wetland habitats. This project provided the required 2.3 acres mitigation for 3 capital projects, but is planned to have approximately 71.6 acres of surplus mitigation in the form of Habitat Enhancement, Created Habitat, Preserved Habitat or Restored Habitat for this un-named creek. In total the project is planned to install approximately 2,800 plants, including Oak trees, Sycamore riparian, Southern Willow Scrub, existing channel, and wetland species. Storm water run-on containing Nutrients and other PWQPs would be treated through infiltration and biofiltration.	✓	✓	✓	✓	✓		✓	Construction to begin in FY18/19 if all funding is secured	Construction contingent on: (1) Completing utility installation (currently in progress) (2) when all of the necessary financial resources have been secured. This strategies is placed as optional mostly due to funding. The project is partially funded with CFD funds, with the remainder is yet to be determined. The overall project budget is approximately $2M. At the time of the B.3 submittal, the plan is to bid the project by 2018. If the jurisdictional strategies fail, the excess mitigation may be used in an overall strategy to add to meet targets and goals.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
2	County of Riverside	Residential/ Commercial	Promote Incentive Partnership Programs: Live Turf Replacement & Outdoor Water Efficiency. Promote Incentive Programs with Water Agencies for BMP Retrofits.	✓	✓	✓	✓		✓	✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) it is determined that there would be an adequate demand for such a program with surveys or other methods; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured.
3	County of Riverside and other Copermittees	Septic Systems	Implement a Partnering Rebate Program for septic system maintenance, with a focus in Target Areas.	✓	✓	✓	✓		✓	✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) other optional strategies are not be implemented or being assessed; and (4) all of the necessary resources have been secured. Gas tax can be used for work in the road right of way for public regulatory compliance. However, other funding (not general funds) will need to be secured specifically for this strategy. At this time no funding source currently exist, and enforcement procedures are used to address failing septic systems.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
4	County of Riverside	Sewer Infrastructure	Implement a Partnering Program with Sewering Agencies (note: County of Riverside does not provide sewer system services) to identify where sewer and storm water infrastructure are in close proximity and subsequently, confirm the absence of flow at nearby major outfall during dry weather for high risk areas.	✓	✓		✓		✓	✓		Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtain full cooperation and continued coordination from the applicable sewering agency; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured.
5	County of Riverside	Onsite Wastewater Treatment System/ Sanitary Sewer Overflow	Implement a program for on-site wastewater treatment (septic) systems. May include mapping and risk assessment, inspection, or maintenance practices.	✓	✓				✓	✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; and (3) septic systems have been determined to be a pollutant sources to the MS4; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining non-Gas Tax or General Fund revenue sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
6	County of Riverside	Existing Development	Provide outreach presentations to elementary, middle, and high school students.	✓	✓	✓	✓	✓	✓	✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; and (3) septic systems have been determined to be a pollutant sources to the MS4; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including scheduling with the school district, obtaining targeted educational material from Principal Permittee for younger audiences, and obtaining the appropriate revenue sources.
7	County of Riverside/ Development Community	New and Redevelopment of all Land Uses	Hold external land development workshops targeting the development community (developers and their engineers).	✓	✓	✓	✓	✓	✓	✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
8	County of Riverside (Rural Areas)	Agricultural/ Equestrian/Livestock Land Uses	Implement outreach program for land owners of equestrian/livestock, and other agricultural operations.	✓	✓		✓	✓		✓	If Nutrient Reduction Goals are not met within a Permit Term, implement this strategy within 1 year of subsequent Permit Term. See Implementation Notes for additional Triggers.	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not being implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.
9	County of Riverside	Commercial, Industrial and Residential Tracts with WQMPs, Municipal	Develop inspection data tracking through GIS applications.	✓	✓	✓	✓	✓		✓	See Implementation Notes	Triggers: Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
10	County of Riverside and Water Agencies/Districts	Commercial, Industrial and Residential	Promote/Partner incentive programs for BMP retrofits (e.g. water smart irrigation controllers, turf replacements programs, residential landscape evaluation program).	✓	✓	✓	✓	✓	✓	✓		Triggers:
											See Implementation Notes	Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.
11	County of Riverside	Municipal Park Areas	Implement a turf replacement program in County Parks.		✓		✓	✓	✓	✓		Triggers:
											See Implementation Notes	Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
12	County of Riverside /Water Districts/NGOs	Residential	Collaborate with partner agencies and groups to promote non-County sponsored incentive programs for BMP retrofits, for example, smart controllers, soil sensors, turf replacement, etc.	✓	✓	✓	✓	✓	✓	✓		Triggers:
											See Implementation Notes	Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.
13	County of Riverside	Residential/ Commercial/ Industrial/Municipal	Outreach to large mobile landscaping service providers/vendors.	✓	✓	✓	✓	✓	✓	✓		Triggers:
											See Implementation Notes	Implementation of this strategy will be triggered if (1) failure to meet any goal pathways and (2) it has been determined by the County of Riverside through adaptive management that implementation is necessary; (3) obtaining positive interest from the targeted audience; (4) other optional strategies are not be implemented or being assessed; and (5) all of the necessary resources have been secured, including obtaining the appropriate revenue sources.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
WMA Strategies												
1	County of Riverside and Regional Jurisdictions	N/A	Coordinate with Integrated Regional Water Management (IRWM) regional water quality managers to identify and apply for grants related to water quality improvement projects (retrofits, stream rehabilitation, or other projects).	✓	✓	✓	✓	✓		✓		Triggers:
											Continuous	Interim goals are not met; progress towards numeric goals is not adequate; staff resources are identified and secured; adaptive management informs the RA's to implement. Resources required to implement strategy: Participation as a stakeholder in the IRWM Program as appropriate; Council approval of an IRWM proposed project; staffing necessary to implement any identified project.
2	County of Riverside and Regional Jurisdictions	N/A	Participate in Santa Margarita River Watershed Nutrient Initiative - Stakeholder Group to exchange information on successes on strategies. Implement or refine existing strategies to utilize other jurisdiction's strategical successes.		✓				✓	✓		Triggers:
											Continuous	Implementation may be triggered if (1) it has been determined by the County of Riverside through adaptive management that implementation is necessary; and (2) all of the necessary resources have been secured.
3		N/A										Triggers:

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Targeted Source Categories	Strategy	Priority Water Quality Pollutants (PWQP) Addressed						Implementation Frequency Schedule		Implementation Notes
				Bacteria	Eutrophic/ Nutrients (HPWQC) Dry Weather Flows	Metals	Sediment	Trash	Dry Weather Flows	FY 2018	Future Fiscal Year(s)	
	County of Riverside and Regional Jurisdictions		Partner/Implement Sustainable Landscapes Program with Water Agencies and Special Districts (e.g., Valley-Wide Recreation and Park Districts) to encourage landscape retrofits.	✓	✓		✓		✓	✓	Continuous	Implementation may be triggered if (1) it has been determined by the County of Riverside through adaptive management that implementation is necessary; and (2) all of the necessary resources have been secured.
4	County of Riverside and Regional Jurisdictions	N/A	Contingent on Regional Board approval of an implementable process, facilitate alternative compliance projects, for new development that are focused on restoring or creating beneficial uses.	✓	✓	✓	✓	✓	✓	✓		Triggers:
											Upon Regional Board Approval	Implementation may be triggered if (1) it has been determined by the County of Riverside through adaptive management that implementation is necessary; and (2) all of the necessary resources have been secured.
5	County of Riverside, Copermittees, Water Agencies/Districts	Residential, Commercial, Agricultural, and Industrial	Collaborate with watershed partners to develop consistent messaging to targeted audiences, such as residential, agricultural, commercial/industrial/residential land uses to conserve water and eliminate dry weather flows.	✓	✓	✓	✓	✓	✓	✓	Upon WQIP Approval	Review existing program and update as necessary to focus on Priority Water Quality Conditions (i.e., Eutrophication).

*NOTES: "Continuous" refers to a strategy that is already being implemented and will continue throughout Future Years.

Table 4-11. Jurisdictional Strategies Selected to Address Eutrophication Impacts in the Middle SMR Subwatershed – Riverside County Flood Control and Water Conservation District

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)														
IDDE-1	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Promote a public reporting mechanism for incidental observations of IC/IDs.	Dry	X	X		X	X	X	X	X	Ongoing	**The District, as a Principal Permittee,** will continue operating a County-wide 1-800 hotline number to enable the public to report illegal dumping (including discharges from Industrial facilities, Commercial sites, and Construction projects), excess irrigation runoff, clogged storm drains, and faded or missing catch basin stencils. The hotline provides schedules for HHW and antifreeze, batteries, oil and paint clean-up locations and is capable of receiving reports in English and Spanish, 24 hours per day, seven days per week. IDDE is included in the JRMP template as part of each Copermittee's SOPs. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees. T**he District, as a Copermittee,** will have a dedicated e-mail address/reporting link, located at http://rcflood.org/npdes/PollutionReporting.aspx, where the public can report any concerns, damage, or illegal dumping to storm drains, dams, basins, levees and/or channels. The District will fund this program through the Santa Margarita Benefit Assessment Fund.
IDDE-2	Riverside County Flood Control and Water Conservation District	Industrial, Residential, Commercial (incl. nurseries)	Train municipal field staff to identify and report ICIDs.	Dry	X	X		X		X	X	X	Ongoing	**The District, as a Principal Permittee,** will continue to provide Copermittees with annual training that focuses on IC/ID identification and reporting. These training courses have become routine SOPs in the JRMP and will be funded through the cooperative Implementation Agreement with the SMR Copermittees. T**he District, as a Copermittee,** will require its field inspection staff to attend this training. The District will fund this program through the District General Zone Fund.
IDDE-3	Riverside County Flood Control and Water Conservation District	Industrial, Residential, Commercial	Implement a District right-of-way inspection program to identify and report Illicit Connections and Discharges.	Dry	X	X		X		X	X	X	Ongoing	**The District, as a Copermittee,** will ensure that its field crews and field contractors are trained to identify, report and initiate elimination of ICIDs within District right-of-ways. The District will fund this program through the District General Zone Fund.
IDDE-4	Riverside County Flood Control and Water Conservation District	Open Spaces	Develop response procedures for homeless issue complaints to prevent or reduce trash and debris from entering receiving waters.	Dry	X	X	X	X	X	X	X	X	Ongoing	**The District, as a Principal Permittee,** will develop response procedures for homeless issue complaints to prevent or reduce trash and debris from entering receiving waters. These procedures will include coordination with the Sheriff's Department and other agencies for further investigation and clean-up. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees. **The District, as a Copermittee,** will implement these procedures to remove the trash and debris associated with

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
														homeless camps from waterways. The District will fund this program through the District General Zone Fund.
IDDE-5	Riverside County Flood Control and Water Conservation District	Existing Development	Identify areas with excessive water use	Dry	X	X		X	X	X	X	X	As needed	**The District, as a Copermittee,** will collaborate with water suppliers to evaluate water usage data to identify areas with excessive water use; such areas are expected to produce proportionately greater non-stormwater runoff so would be targeted for IDDE inspection. The District will fund this program through the Santa Margarita Benefits Assessment fund with in-kind services from water supply agencies.
IDDE-6	Riverside County Flood Control and Water Conservation District	Other Point and Non-Point Sources	Assessment of Permitted flows	Dry	X	X				X		X	Complete by 2023	**The District, as a Principal Permittee**, will conduct a study to evaluate the source contributions of dry weather flow and nutrient loading from natural and permitted flows. The project will include: permitted discharge & purple pipe inventory; natural sources inventory (rising groundwater, springs, etc.); assessment of flows covered by de-minimis permits; and flow characterization. The products will include flow and load estimates, a map of these sources, and recommendations for management approaches. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees and seek assistance and in-kind services from water agencies and other SMR stakeholders.
Development Planning (Prov E.3)														
DEV-1	Riverside County Flood Control and Water Conservation District	New Development, Redevelopment, Residential	Implement Updated BMP Design Manual.	Both	X	X	X	X	X	X	X	X	Ongoing	**The District as a Copermittee** will review WQMPs for conformance with the BMP Design Manual as requested by County of Riverside staff, where there is flood plain encroachment and for projects requiring an encroachment permit from the District. In addition, the District as Copermittee will evaluate its capital improvement projects to determine Priority Development Project (PDP) criteria applicability and will prepare Project Water Quality Management Plans in conformance with the BMP Design Manual for projects meeting PDP criteria. The District will fund this program through pan check review fees and through the District General Zone Fund.
DEV-2	Riverside County Flood Control and Water Conservation District	New Development, Redevelopment, Residential	Update the BMP specifications (Soil mix, plant types, configuration) in the BMP Design Manual to enhance retention of nutrients.	Both	X							X	Ongoing	**The District, as Principal Permittee,** is using its LID Testing and Demonstration Facility to monitor and study the most recent approaches and techniques for biofiltration systems. These efforts include evaluating different soil media, plant palettes, and system configurations to optimize nutrient retention. This research will inform development of improved designs for biofiltration systems for nutrient retention and the District will ensure that the BMP Design Manual is revised to incorporate recommendations arising from this research. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
DEV-3	Riverside County Flood Control and Water Conservation District	New Development, Redevelopment, Residential	Update the BMP Design Manual with landscape design and maintenance guidance	Both	X	X		X	X	X	X	X	Ongoing	**The District, as Principal Permittee**, will develop improved guidance for the design, implementation, and maintenance of landscaping for development projects. The guidance will focus on reducing the use of fertilizers, selection of plants, and outline maintenance procedures to prevent non-stormwater flows and improve management and containment of landscape clippings. The BMP Design Manual will be updated with this guidance.
DEV-4	Riverside County Flood Control and Water Conservation District	New Development, Redevelopment, Residential	Train staff on Updated BMP Design Manual.	Both	X	X	X	X	X	X	X	X	Annually	**The District, as a Principal Permittee,** will revise its training module to include the updates to the BMP Design Manual and deliver the module to the Copermittees. **The District, as Copermittee**, will ensure that its staff attends this training. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.
Construction Management (Prov E.4)														
CON-1	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Train staff on implementation of BMPs that reduce the potential of HPWQC and PWQP loading, and are site specific and seasonally appropriate to the construction phase, year round.	Both	X	X		X	X	X	X	X	Annually	**The District, as a Principal Permittee**, will continue providing annual training to enable Copermittees to effect proper implementation of year-round site-specific/phase-specific construction BMPs, CGP requirements, and SWPPPs at municipal construction sites. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees. **The District, as a Copermittee,** will ensure that its staff attend and apply this training to the preparation and oversight of SWPPPs prepared for District projects. The District will fund this program through the District General Zone Fund.
CON-2	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Require preparation and implementation of SWPPPs	Both	X	X	X	X	X	X	X	X	Annually	**The District, as Copermittee,** will review SWPPPs and inspect its construction sites for conformance with the Stormwater and Non-Stormwater Pollution Control provisions of its standard specifications and contract documents.
Existing Development Management (Prov E.5)														
ED-1	Riverside County Flood Control and Water Conservation District	Municipal Facilities	Inspect and maintain flood control facilities.	Both	X	X	X		X	X	X	X	Ongoing	**The District, as a Copermittee**, will continue maintaining its facilities by removing debris and excess sediment, repairing eroded areas, tracking slopes, maintaining vegetated areas, rehabilitating and/or replacing structural rip-rap, repairing grout, removing and replacing concrete channel linings, repairing washouts, etc. The District will fund this program through the District General Zone Fund.
ED-2	Riverside County Flood Control and Water Conservation District	Existing Development, parks and recreation, orchards/vineyards/nurseries, horse ranches/equestrian, other agriculture, open space	Inspect District outfalls and coordinate abatement activities with affected jurisdictions.	Both	X	X		X					Annually	**The District, as a Copermittee,** will inspect all of its outfalls twice per year and work with affected jurisdictions to provide outreach materials to the general public to abate dry weather flows. The District will fund this program through the Santa Margarita Benefit Assessment Fund.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
ED-3	Riverside County Flood Control and Water Conservation District	Existing Development	Provide funding for Riverside County Fire Department HAZMAT Response Program.	Both	X	X	X	X		X	X	X	Annually	**The District, as a Principal Permittee**, will provide funding ($1,825,000 over period FY17/18 to FY21/22) to Riverside County Fire Department for watershed-wide hazardous-material incident response and clean-up.
Enforcement Response Plans (Prov E.6)														
ERP-1	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial, parks and recreation, orchards/vineyards/nurseries, horse ranches/equestrian, other agriculture, open space	Require the implementation of the ERP to ensure proper use of BMPs to prevent or reduce the discharge of pollutants into MS4 networks.	Both	X	X	X	X	X	X	X	X	Ongoing	**The District, as a Principal Permittee,** will provide training to the Copermittees on implementation of the ERP during existing development inspections. Funding will be provided through the cooperative Implementation Agreement with the SMR Copermittees and the use of the District General Zone Fund. **The District, as a Copermittee,** will ensure that its inspection staff attends and applies ERP training to investigations arising from IDIC notifications.
ERP-2	Riverside County Flood Control and Water Conservation District	Construction Activities	Require the implementation of the ERP to ensure that private construction activities comply with the Construction General Permit and Copermittees' Stormwater Ordinances.	Both	X	X	X	X	X	X	X	X	Ongoing	**The District, as a Principal Permittee,** will provide training to the Copermittees on proper implementation of the ERP during construction site inspections. Funding will be provided through the cooperative Implementation Agreement with the SMR Copermittees and the use of the District General Zone Fund. **The District as a Copermittee** will ensure that its inspection staff attends and applies ERP training to oversight of District construction activities. The District will fund this program through the District General Zone Fund.
Public Education and Participation (Prov E.7)														
PUB-1	Riverside County Flood Control and Water Conservation District	Industrial, Commercial, Residential	Collaborate with watershed partners to develop consistent messaging to targeted audiences, such as commercial residents to conserve water and reduce dry weather flows.	Both	X	X	X	X	X	X	X	X	Ongoing	**The District, as a Principal Permittee and a Copermittee,** will collaborate with Copermittees and watershed partners to develop and deliver a comprehensive education and outreach program that will enable consistent messaging to be delivered to targeted audiences and encouraging practices that conserve water and eliminate excess irrigation runoff. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.
PUB-2	Riverside County Flood Control and Water Conservation District	Existing Development	Develop and provide outreach material to mobile landscape service providers that focuses on runoff and nutrient reduction.	Both	X		X		X	X		X	Ongoing	**The District, as a Principal Permittee and a Copermittee,** will develop and provide educational materials and outreach, incorporating technical content developed under PUB-1, to landscaping service providers. The materials will focus on preventing irrigation runoff, minimizing fertilizer and pesticide use, and proper containment and disposal of material. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
PUB-3	Riverside County Flood Control and Water Conservation District	Residential	Provide outreach presentations to elementary, middle, and high school students to ensure that environmental protection is addressed early-on during the academic process.	Both	X	X		X	X	X		X	Ongoing	**The District, as a Principal Permittee and a Copermittee,** will provide educational materials, incorporating informational content developed under PUB-1, to Homeowner Associations. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.
PUB-4	Riverside County Flood Control and Water Conservation District	Existing Development, parks and recreation, orchards/vineyards/nurseries, horse ranches/equestrian, other agriculture, open space	Enhanced Jurisdictional: Coordinate/develop outreach materials in support of Copermittee enhanced inspection, outreach & enforcement programs	Both	X	X		X	X	X	X	X	Ongoing	**The District, as a Principal Permittee and a Copermittee,** will coordinate the development and distribution of an informational brochure for nurseries, vineyards, and horse ranches that focus on BMPs that reduce nutrients in runoff. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.
PUB-5	Riverside County Flood Control and Water Conservation District	Existing Development, parks and recreation, orchards/vineyards/nurseries, horse ranches/equestrian, other agriculture, open space	**Enhanced Jurisdictional:** Develop a webpage to ensure Copermittees and the general public have access to the latest NPDES information.	Both	X				X	X	X	X	Ongoing	**The District, as a Principal Permittee and a Copermittee**, will further develop a website intended to encourage community stewardship of the Santa Margarita River. The District will fund this program using NPDES Benefit Assessment funds.
Optional Jurisdictional Strategies and Schedule														
OPT-1	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Perform infiltration-testing at District basins and outfalls to collect data to assess the feasibility of regional recharge facilities or individual infiltration BMPs.	Both	X	X	X					X	Ongoing	**The District, as a Copermittee,** will evaluate District basins to determine opportunities for managing these facilities to optimize infiltration. Enhancing infiltration rates within existing infrastructure may increase wet and dry weather flow capture thereby reducing pollutant loading. Revised basin management practices will be implemented starting in 2021 as determined by need through the adaptive management process to effect additional load reductions. The District will fund this program through the District General Zone Fund.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
OPT-2	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Partner with community groups to engage the public in promoting educational programs and community cleanups.	Both	X	X		X	X				Ongoing	**The District, as a Copermittee,** will partner with community groups to further enable the public to participate in channel cleanups. Clean-ups will remove anthropogenic bio-degradable debris that can contribute to nutrient loading. The annual Santa Ana River clean-up event is a model. The District will fund this program through the Santa Margarita Benefit Assessment Fund.
OPT-3	Riverside County Flood Control and Water Conservation District	New Development, Residential, Commercial, Industrial	Evaluate the suitability of regional basins.	Both	X	X						X	Ongoing	**The District, as a Copermittee,** will incorporate water quality features into a planned regional detention basin upstream of Interstate15 within the City of Wildomar. The District will fund this program through the District General Zone Fund.
Optional WMA Strategies and Schedule														
WMA-1	Upper and Middle Watershed Jurisdictions	IDDE	Partner with Water District(s) on pilot projects to abate dry weather flows.		X	X		X					As needed	**The District, as a Principal Permittee,** will screen the watershed's MS4 infrastructure for opportunities to construct dry weather flow diversions to the sanitary sewer for outfalls where persistent dry weather flows are not being abated by non-structural control strategies. The District will fund this program through the Santa Margarita Benefit Assessment Fund.
WMA-2	Upper and Middle Watershed Jurisdictions	IDDE	Coordinate incentive programs for reducing outdoor water use with Water Districts		X	X				X	X		As needed	**The District, as a Principal Permittee,** will partner with Water Districts on grant funding opportunities that encourage low water landscaping, use of rain barrels, etc. The District will fund this program through the cooperative Implementation Agreement with the SMR Copermittees.
WMA-3	Upper and Middle Watershed Jurisdictions	New Development	Update WMAA.		X		X			X	X		As needed	**The District, as a Principal Permittee,** will prepare an updated WMAA projects created with reference Integrated Water Resource Manageme Conservation Plan. The District will fund the WMAA update through the Copermittees unless grant opportunities can be located.
WMA-4	Upper and Middle Watershed Jurisdictions	New Development	Update Water Quality Equivalency Calculations as part of the Alternative Compliance program.		X	X	X	X		X	X		As needed	**The District, as a Principal Permittee,** will update water quality equivalency calculations as part of the regional criteria for alternative compliance. The District will fund this effort through the cooperative Implementation Agreement with the SMR Copermittees.
WMA-5	Upper and Middle Watershed Jurisdictions	New Development	Submit Grant Applications to support the development and/or implementation of the WMAA and Alternative Compliance Program.		X	X	X	X		X	X		As needed	**The District, as a Principal Permittee,** will search for applicable grant opportunities and partnerships with Copermittees, stakeholder groups, State and Federal agencies, non-profit organizations, etc. to develop and/or implement the WMAA and Alternative Compliance program. The District will fund the development of the WMAA through the cooperative Implementation Agreement with the SMR Copermittees.
WMA-6	Upper Watershed Jurisdictions	Various Point and Non-Point Sources	Develop a Stormwater Resources Plan.		X	X	X			X	X		As needed	**The District, as a Principal Permittee,** will seek partnerships with Water Districts to develop a Stormwater Resources Plan that will identify and select, through a systematic process of prioritization, candidate projects for funding consideration. The District will seek grant funding opportunities to assist Water Districts in funding this effort.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule		Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Food Supply	FY2018	Future Fiscal Years	
WMA-7	Upper and Middle Watershed Jurisdictions	Various Point and Non-Point Sources	Coordinate with the SMR Nutrient Initiative Group to share watershed-related information.		X								As needed	**The District, as a Principal Permittee,** will continue providing support for the analysis of eutrophication and nutrient loading in the upper Santa Margarita River and tributaries. The District will fund this support through the cooperative Implementation Agreement with the SMR Copermittees.
WMA-8	Upper and Middle Watershed Jurisdictions	IDDE and Various point and Non-Point Sources	Coordinate with the SMR IRWM group to share watershed-related information.		X	X		X		X	X		As needed	**The District, as a Principal Permittee,** will seek partnerships with Water Districts to manage water resources, turf removal programs, landscape water reduction, use of recycled water, BMP implementation in Ag and equestrian land uses, etc. The District will seek grant funding opportunities to assist Water Districts in funding these programs.
WMA-9	SMR	Various Point and Non-Point Sources	Coordinate with the Consultation committee to provide updates and share watershed-related information.		X	X		X	X	X	X		As needed	**The District, as a Principal Permittee,** will seek partnerships with Water Districts, stakeholder groups, non-profit organizations, etc. to discuss the status of the health of the watershed in efforts to identify projects to address common issues.

4.2.1.3 Optional Jurisdictional

Optional jurisdictional strategies include those that Copermittees and the City of Menifee may implement to achieve interim and final numeric goals. As part of the five-year assessment process, implementation of strategies will be evaluated against progress towards goals. Where interim goals are met and the current strategies and schedules are determined to be adequate to achieve the subsequent interim or final goal, Copermittees and the City of Menifee may adjust current strategies. Where interim goals are not achieved, and/or it is determined that the current strategies, even if implemented on accelerated schedules, would not achieve future interim or final goals, optional jurisdictional strategies may be triggered and implemented as resources allow. Implementation is contingent on the time needed to assemble resources and the availability of funding. The process for identifying optional jurisdictional strategies is summarized in **Figure 4-11**. Optional strategies for each Copermittee and the City of Menifee are detailed in the jurisdictional strategies tables above. The optional jurisdictional strategies include optional programs, retrofits, and stream rehabilitation programs per Permit Provision B.3.b.

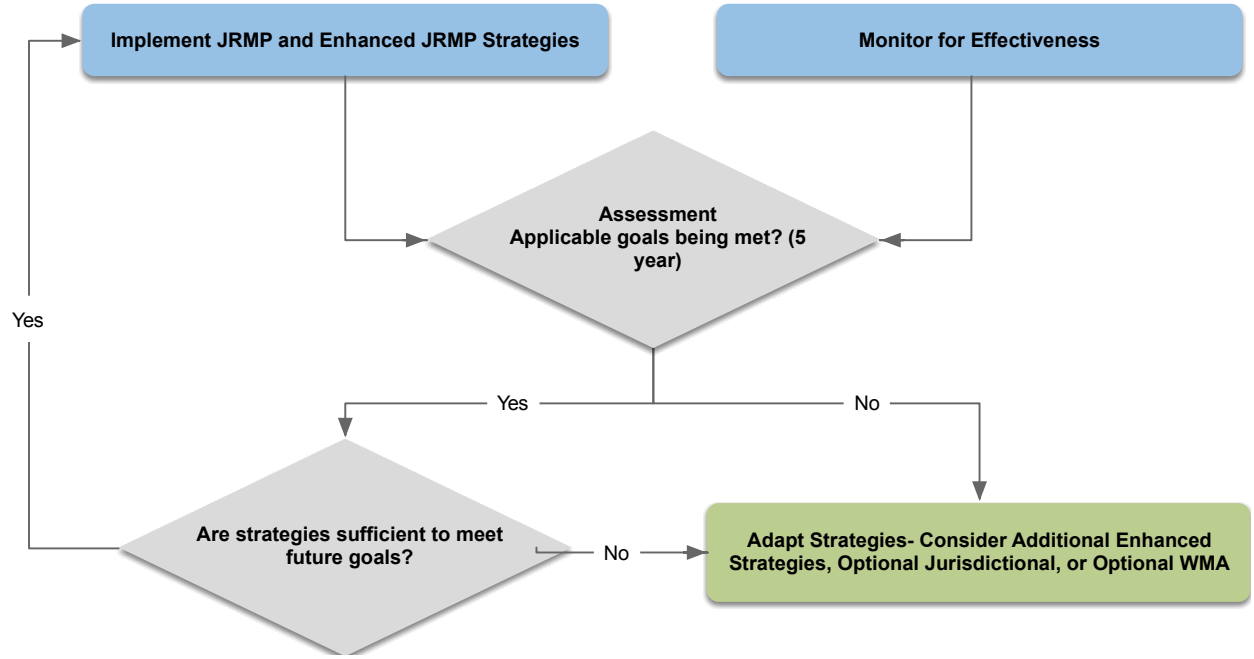

Figure 4-11. Adaptive Management Process to Identify Additional Strategies

4.2.1.3.1 Enhanced Street Sweeping

As described in the Jurisdictional Strategies, street sweeping can be an effective strategy to mediate pollutants that are transported by sediment or leaf debris, including nutrients and other pollutants (e.g. metals, oil and grease, bacteria, and trash), into the MS4s. Street sweeping frequencies and routes could be targeted to more effectively remove debris from problem areas identified by the Copermittees and the City of Menifee.

4.2.1.3.2 Coordination with Water Districts

The Copermittees and the City of Menifee could coordinate with water districts to identify areas with high water usage during dry months, and, thereby, pinpoint and address potential sources of dry weather flows. The coordination could include community surveys and enforcement efforts for over-irrigation, and incentive programs to encourage proper irrigation practices.

4.2.1.3.3 Capital Improvement Program Projects

Capital Improvement Program (CIP) projects could include structural BMPs that treat and/or reduce dry weather and stormwater runoff. These type of BMPs are designed to treat pollutants based on site-specific conditions. Typically, the total cost of structural BMPs tend to be higher than non-structural BMPs, as installation and maintenance is required. Furthermore, extensive studies are needed to select appropriate devices that will treat the desired pollutants at each site. The installation of structural BMPs may be more cost-effective if these are considered in initial planning phases for specific projects. These projects could provide a multi-pollutant benefit in reducing runoff.

4.2.1.3.4 Dry Weather Treatment

Dry weather retrofits (and infiltration or treatment) could be an effective strategy to reduce dry weather flows and reduce multiple pollutants. A dry weather retrofit may include the reconfiguration of the outlets of existing flood control basins to allow more time for evapotranspiration. This could be particularly effective in eliminating non-stormwater discharges to receiving waters. Infiltration BMPs may include infiltration basins, trenches, and galleries, bioretention systems, dry wells, hybrid bioretention/dry wells, or permeable pavements. Infiltration BMPs could be considered in areas with appropriate soils that promote infiltration and where groundwater augmentation is feasible (i.e., stormwater quality would not affect groundwater basin).

The Copermittees and the City of Menifee have reason to question the feasibility of infiltration (independent of a flood control function) in large portions of the Middle SMR Subwatershed that are served by MS4 facilities. Investigations and discussions with stakeholders during this planning process revealed three concerns:

1. First, the condition of the groundwater below most of the MS4 facilities is sensitive. There are two aquifers, one on top of the other, separated by a leaky clay layer. The aquifer on top is of poor quality, while the deeper aquifer is of better quality and is the one used for water supply. There is concern that if the surface conditions are changed with infiltration basins, the surface water will enter the top aquifer and force poor quality water from it to enter the deeper aquifer and, thereby, jeopardize drinking water supplies.

2. Second, infiltration rates are often poor to non-existent due to high groundwater conditions. The RCFCWCD discovered this as a result of infiltration tests completed as it investigated the feasibility of potential infiltration basin sites.
3. Third, there is a concern for water rights. Surface water in the SMR WMA has been adjudicated. Camp Pendleton is downstream, and has a claim on surface flows generated in the Middle SMR Subwatershed. If surface flows from the Middle SMR Subwatershed do not exceed certain volumes, they must be replaced, usually with much more expensive Colorado River water. Thus, surface flows diverted to groundwater would have to be replaced, at a high cost, to satisfy the claim.

Taken together, these concerns may be difficult to overcome. They may effectively prohibit the selection of infiltration as an optional strategy in many areas of the Middle SMR Subwatershed.

4.2.2 Strategies to Address Eutrophication Impacts and Nutrients in the Lower SMR Subwatershed

The Permit establishes that WQIP strategies should be identified on the basis of their likelihood to "effectively prohibit non-storm water discharges to the MS4, reduce pollutants in storm water discharges from the MS4 to the MEP, protect the beneficial uses of receiving water from MS4 discharges, and/or achieve the interim and final numeric goals identified under Provision B.3.a."

Four primary jurisdictional strategy programs are required under the 2013 Permit, each requiring its own inventory of potential pollutant sources. These include:

1. Illicit Discharge Detection and Elimination (MS4 outfall inventory);
2. Development Planning (Priority development project [PDP] and BMP inventory);
3. Construction Management (Construction site inventory); and
4. Existing Development Management (Industrial, Commercial, Municipal, and Residential inventories).

San Diego County has developed inventories for each of these categories. Known and suspected sources contributing to nutrient loading are discussed in detail in **Chapter 2**. These known and suspected sources include persistently flowing outfalls and specific land use types. Modeling completed for the SMR identified irrigated agriculture, orchards, vineyards and nurseries, open scrublands and grasslands, and residential land uses as the largest contributors of total nitrogen load. Total phosphorus loading is being contributed by roads, orchards, vineyards and nurseries, open scrublands and grasslands, and residential land uses. Jurisdictional strategies are targeted towards reducing dry weather flow and addressing the types of land use sources that are within the MS4 drainage area.

Additional optional strategies have also been identified. These optional strategies are currently being implemented, are planned for implementation, or may be triggered for implementation in the future to address the HPWQC.

Strategies to address nutrients in Rainbow Creek and eutrophic conditions in the SMR Estuary were chosen on the basis of their expected effectiveness in reducing pollutant sources and their suitability and potential to be implemented in order to achieve required goals. Non-structural strategies represent the first line of defense for management of stormwater pollutants. These institutional programs tend to be the most cost-effective options for water quality improvement because they focus on controlling the sources of pollution throughout the landscape before

pollutants can be washed downstream by stormwater runoff. During development of previous WQIPs throughout the San Diego Region (San Diego Regional Water Quality Control Board 2016b), maintenance and enhancement of non-structural strategies has been acknowledged by the Regional Water Board to reduce pollutant loads by approximately 10%.

Schedules for strategy implementation reflect the time necessary to fully fund, develop, initiate, and complete the chosen strategies. Strategies with relatively high benefit outcomes and low resource requirements are scheduled for earlier implementation. Strategies planned for later years may have implementation requirements that depend on the outcomes of earlier strategies, or might have significant funding needs.

While the chosen strategies focus on nutrients, these strategies address multiple pollutant sources and constituents as shown in each of the jurisdictional strategy tables above. Optional strategies are also presented in the jurisdictional strategy tables above. Optional strategies may be triggered on the basis of a set of given conditions, such as necessity or as resources are available. The strategies and schedules are subject to change, and are contingent upon programmatic requirements and funding availability. They will be modified through the adaptive management process as needed.

4.2.2.1 Modeling of Structural Strategies for Rainbow Creek

To comply with the Nutrient TMDL in Rainbow Creek as required by Attachment E.3, Table 3.3, of the Permit, the County of San Diego completed a modeling effort to identify the most effective structural strategies for reducing nutrient loading. The purpose of the modeling is to provide reasonable assurance that a specific set of actions will result in sufficient reduction in nutrients to meet compliance with the Final Effluent Limitations assigned to the County of San Diego in Attachment E.3.b.2(b)(ii). To ensure consistency with modeling efforts throughout the watershed, the Rainbow Creek modeling effort built upon modeling completed for the SMRNIG investigation for the SMR Estuary and river (Sutula et al, 2016). That Hydrological Simulation Program FORTRAN (HSPF) watershed model was recently updated and the details can be found in the updated allocation memorandum (Tetra Tech, May 2016) and in Appendix 4A. The updated model improved the representation of land uses within San Diego County and provided additional hydrological refinements to improve the model simulation results for the Rainbow Creek watershed. This updated model was then used to simulate potential structural strategies to reduce nutrients in Rainbow Creek.

The modeling results demonstrated that, given the constraints and conditions of the Rainbow Creek watershed, biofiltration that is designed to provide advanced nutrient treatment is the most appropriate strategy to address wet weather discharges from outfalls to Rainbow Creek. The flat topography in this specific part of the watershed combined with a shallow groundwater level is a constraint for the design of structural BMPs. Wetland channels are recommended and can in some cases be sited in the public right-of-way to intercept stormwater and dry weather runoff. Stream restoration can also be an effective strategy to help restore beneficial uses to degraded creeks and enhance nutrient capture and assimilation. Typical stream restoration projects include reshaping of the channel, installation of features to enhance fluvial processes, and replanting of riparian vegetation.

The County of San Diego proposes to implement structural strategies to address wet weather outfall discharges into Rainbow Creek. Work on the siting and design of these structural BMPs is underway. Funding has been secured through Fiscal Year 19-20 to select sites for structural BMP

installation and to move forward with the implementation of BMPs as soon as possible. Currently, the structural BMPs in the Rainbow Creek watershed are being planned to specifically target areas with the highest observed loading of nutrients. The model shows that 6 of the 19 outfalls in the Rainbow Creek subwatershed account for 77% of the total nutrient loading coming from County MS4. Focusing the structural BMPs (nutrient-sensitive biofiltration, wetland channels, or an equivalent approach) to reduce loading at these sites is being analyzed by the engineering and design team. The ongoing work includes conducting a constraints analysis and preparing preliminary engineering designs which will be used to evaluate whether this is the most effective and efficient approach to reducing nutrient loading in the watershed during wet weather. During the design phase, alternate BMPs than the ones listed here may be selected so long as they provide the equivalent level of nutrient load reduction. The level of flow treated for each individual BMP will also be determined and targeted to achieve the appropriate load reductions during the design phase.

The strategies, as determined by reasonable assurance compliance modeling, that are proposed for implementation in order to meet the Rainbow Creek Nutrient TMDL are summarized in **Table 4-12**. Additional details on the modeling techniques and results can be found in Appendix 4A. As required by Permit Provision B.3, this modeling effort provides reasonable assurance that implementation of these proposed structural strategies or equivalent structural strategies will achieve compliance with the Final Effluent Limitations assigned to the County of San Diego.

The County of San Diego's five-year budget forecast identifies the need for funding to continue for the structural strategies in Rainbow Creek watershed and it is expected that funds will be available for this work, since achieving compliance with the Nutrient TMDL is a priority for the County of San Diego. However, it should be noted that the Watershed Protection Program of San Diego County is currently a General Fund program and thus funding must be secured on an annual basis. Progress and status of implementation of the structural BMPs in the Rainbow Creek watershed will be updated annually as part of the Watershed annual reports.

The County of San Diego has already begun the design phase for wetland channels to capture runoff from approximately 200 acres of the southern portion of Rainbow Valley, as shown in Figure 4-12. This includes runoff from several of the large nurseries in the valley and treats the drainage areas associated with HST-01 and SMG-089. The proposed channel wetlands plan to include segments of channel along 5th Street and Huffstatler Street north of 5th Street. The design will reconfigure the existing channels and include a gravel substrate topped by soil media and vegetation creating a subsurface flow wetland which will maximize nutrient reduction through biological uptake, microbial interactions, and anaerobic zone for denitrification. The finalized designs for this structural BMP are scheduled to be completed by June 2019, with a construction bid package awarded in late 2019. The County is working towards installing the remaining structural BMPs in a timely manner so that monitoring results can demonstrate compliance with the Rainbow Creek TMDL prior to the December 31, 2021 deadline.

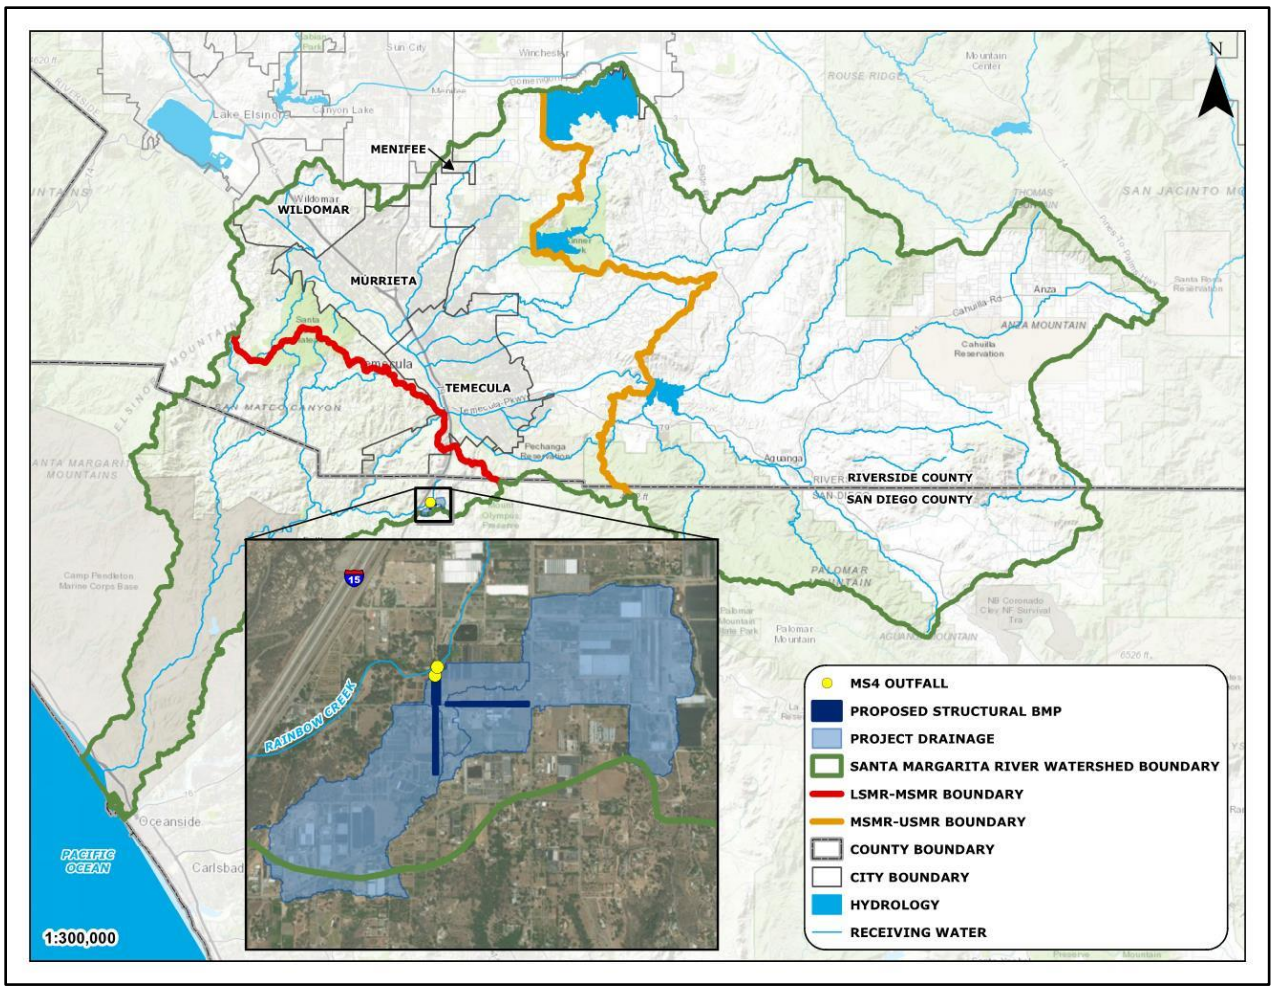

Figure 4-12. Proposed Structural BMP Currently in Design Phase in Rainbow Valley

Table 4-12. Proposed Structural Strategies to Meet Compliance with Rainbow Creek Nutrient TMDL

Strategy	Units	Quantity[1]	Scheduled Compliance
Nutrient-Sensitive Biofiltration (Based on six priority outfalls) or equivalent	acres	0.21	12/31/2021
Wetland Channels (Based on six priority outfalls) or equivalent	acres	0.39	12/31/2021
Stream Restoration and Channel Improvements or equivalent (Public-Private Partnerships)	linear feet	2,143 [2]	12/31/2021

1. Note that quantities are based on planning-level, desktop analyses. Actual quantities will vary during implementation on the basis of site-specific designs, conditions, and constraints.
2. Sized based on rate of 0.075 lbs/ft/yr removed of TN (Chesapeake Stormwater Network and Center for Watershed Protection, 2014).

4.2.2.2 Jurisdictional Strategies

The Copermittees have identified jurisdictional strategies that will be implemented as part of their JRMPs. Achievement of water quality benefits will ultimately be measured against the interim and final numeric goals as discussed in **Section 3.3.1**. The key sources for the County of San Diego and the relative loading of nutrients from those sources to the County's MS4s provide the foundation for strategy selection. The priority sources and relative nutrient loading are summarized for the County of San Diego in **Table 4-13**.

Table 4-13. Summary of Key Sources of Nutrients for the County of San Diego

Key Sources	Total Nitrogen[1]	Total Phosphorus[1]
Orchards, Vineyards, Nurseries	56.60%	53.40%
Residential Areas/Activities	20.90%	23.30%
Other Agriculture	5.00%	4.50%

1. As a percentage of the total loading to the Copermittee's MS4.

The jurisdictional strategies can be categorized into three types:

1. Strategies building on the required JRMP elements in Provision E of the Permit. These include the JRMP requirements as well as modifications and enhancements within existing programs to provide a more focused approach, specifically addressing nutrients;
2. Optional jurisdictional strategies that may be implemented to achieve the interim and final goals; and
3. Coordinated strategies involving collaboration amongst multiple agencies within the WMA working towards common goals.

Under the Permit, strategies are required to be identified for the following six components. The required components are:

1. Illicit Discharge Detection and Elimination (MS4 outfall inventory) [Provisions D.2 and E.2];
2. Development Planning (PDP and BMP inventory) [Provision E.3];

3. Construction Management (Construction site inventory) [Provision E.4];
4. Existing Development Management (Industrial, Commercial, Municipal, and Residential inventories) [Provision E.5];
5. Enforcement Response Plans [Provision E.6]; and
6. Public Education and Participation [Provision E.7].

Table 4-14 presents the jurisdictional strategies planned for implementation to address nutrients in the Lower SMR Subwatershed.

Table 4-14. Jurisdictional Strategies for the Lower SMR Subwatershed

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov E.2)															
IDDE-1	County of San Diego	Industrial, Residential, Commercial	Maintain storm water conveyance system map to facilitate Illicit Discharge, Detection, and Elimination program.	Dry	X	X		X		X	X	X	X	Ongoing	Ongoing updates to mapping as needed.
IDDE-2	County of San Diego	Industrial, Residential, Commercial (incl. nurseries),	Utilize municipal personnel and contractors to identify and report Illicit Connections and Discharges.	Dry	X	X		X		X	X	X	X	Ongoing	Annual stormwater training for municipal personnel and contractors as needed.
IDDE-3	County of San Diego	Industrial, Residential, Commercial	Updated focused training for County field staff.	Dry	X	X		X	X	X	X	X	X	Annually	Training is updated and will be administered as needed.
IDDE-4	County of San Diego	Onsite Wastewater Treatment Systems	Address septic system failures where observed.	Dry	X	X		X	X	X	X	X	X	Ongoing	Per the LAMP policy, DEH will respond to septic system failures as appropriate.
IDDE-5	County of San Diego	Industrial, Residential, Commercial	Facilitate public reporting of Illicit Connections and Illicit Discharges via email.	Dry	X	X		X	X	X	X	X	X	Ongoing	A bilingual hotline, dedicated e-mail address, and multiple online reporting tools will continue to be supported.
IDDE-6	County of San Diego	Industrial, Residential, Commercial	Bilingual hotline (I Love a Clean San Diego) to provide better customer service.	Dry	X	X		X	X	X	X	X	X	Ongoing	The I Love A Clean San Diego hotline will continue to be supported.
IDDE-7	County of San Diego	Industrial, Residential, Commercial	Implement practices and procedures to address spills with the potential to enter the storm drain system.	Dry	X	X		X		X	X	X	X	Ongoing	A NOV will be issued by DEH when appropriate per the LAMP policy. Prompt follow up and mitigation is implemented.
IDDE-8	County of San Diego	Sanitary Sewer Overflow	Coordinate spill response with responsible sanitary sewer agencies.	Dry	X	X		X		X	X	X	X	Ongoing	Implement plan to inform the public of risks associated with sewer spills, conducting sampling, reporting, posting signs, etc.
IDDE-9	County of San Diego	Industrial, Residential, Commercial	Utilize municipal personnel and Contractors to monitor storm water outfalls for discharges of potential Illicit Connections and Illicit Discharges.	Dry	X	X	X	X	X	X	X	X	X	Ongoing	This is part of our IDDE program.
IDDE-10	County of San Diego	Industrial, Residential, Commercial	Develop and implement a strategy for investigating and addressing Illicit Connections and Illicit Discharges.	Dry	X	X		X		X	X	X	X	Ongoing	This is part of our IDDE program
IDDE-11	County of San Diego	Open Spaces	Refer homeless issue complaints to Sheriff or appropriate jurisdictions.	Dry	X	X	X	X		X	X	X	X	Ongoing	This is part of our IDDE program
Development Planning (Prov E.3)															
DEV-1	County of San Diego	New and Redevelopment	Priority Development Projects (PDPs): In addition to requirement for all development projects, implement or require implementation of onsite structural BMPs to control pollutants and manage hydromodification for PDPs.	Both	X	X	X	X		X	X	X	X	Ongoing	The County BMP Design Manual requires all PDPs to implement PC and HMP BMPs. These requirements are captured in the WPO and County's BMP DM.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
DEV-2	County of San Diego	New and Redevelopment	Update BMP Design Manual procedures to specify storm water requirements applicable to development and redevelopment projects, identify and design appropriate BMPs, establish maintenance criteria, and establish where implemented alternative compliance options.	Both	X	X	X	X	X	X	X	X	X	Ongoing	Updated to reflect the Regional Model BMP DM with additional changes to incorporate County implementation practices.
DEV-3	County of San Diego	New and Redevelopment	Conduct internal (staff) training on the updated BMP Manual.	Both	X	X	X	X		X	X	X	X	Ongoing	Initial training was provided and will be continued as needed.
DEV-4	County of San Diego	New and Redevelopment	Impose legal authority to ensure all development and redevelopment projects are in compliance with all post construction requirements.	Both	X	X	X	X	X	X	X	X	X	Ongoing	The Watershed Protection Ordinance was updated in FY16 to include modifications necessary as the result of the updated permit and the inclusion of applicant-implement offsite alternative compliance.
DEV-5	County of San Diego	New and Redevelopment	Update County codes, ordinances, and storm water design standards consistent with the permit and the updated BMP Manual.	Both	X	X		X		X	X	X	X	One time	The Watershed Protection Ordinance was updated in FY16 to include modifications necessary as the result of the updated permit and the inclusion of applicant-implement offsite alternative compliance.
Construction Management (Prov E.4)															
CON-1	County of San Diego	Construction Waste Management	Require implementation of BMPs that are site specific, seasonally appropriate and appropriate to the construction phase, year round.	Both	X		X	X	X	X	X	X	X	As necessary	Every project requires implementation of site specific construction BMPs, seasonably appropriate and appropriate to the construction phase.
CON-2	County of San Diego	Construction Waste Management	Impose legal authority to ensure inventoried construction projects are in compliance with all requirements.	Both	X	X	X	X	X	X	X	X	X	As necessary	The Watershed Protection Ordinance is the current legal authority to insure inventoried construction projects are in compliance with all requirements.
CON-3	County of San Diego	Construction Waste Management	Provide internal staff training related to construction storm water management.	Both	X	X	X	X	X	X	X	X	X	Annually	Training will be administered as needed.
Existing Development Management (Prov E.5)															
ED-1	County of San Diego	Industrial, Commercial, Municipal, Residential	Maintain and update a watershed-based inventory of existing development (i.e. commercial, industrial, municipal and residential areas).	Both	X	X	X	X		X		X	X	Ongoing	Inventory for these items is tracked in an electronic database.
ED-2	County of San Diego	Industrial, Commercial, Municipal, Residential	Improve the tracking of watershed based inventories via consolidated database.	Both	X	X	X	X	X	X		X	X	Ongoing	Inventory for these items is tracked in an electronic database.
ED-3	County of San Diego	Industrial, Commercial, Municipal, Residential	Designate a minimum set of BMPs required for all existing development inventories, including special event venues. The designated minimum BMPs must be specific to facility or area types and pollutant generating activities, as appropriate.	Both	X	X	X	X	X	X		X	X	Annually	The JRMP establishes minimum BMPs for all land use types.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
ED-4	County of San Diego	Municipal	Pet waste management and outreach in County Parks.	Both	X	X				X		X	X	Ongoing	Determine if pet waste is currently addressed in County Parks in this area and increase outreach if needed.
ED-5	County of San Diego	Municipal	Implement a schedule or operation and maintenance activities for the storm water conveyance system and related structures.	Both	X	X		X		X		X	X	Ongoing	Stormwater conveyance system maintenance is referred to appropriate departments when needed.
ED-6	County of San Diego	Streets	Implement a schedule of operation and maintenance for County paved and unpaved roads.	Both	X	X		X		X		X	X	Ongoing	County Road Crews employ a schedule for maintenance of County Roads.
ED-7	County of San Diego	Residential	Promote and encourage implementation of designated BMPs in residential areas.	Both	X	X				X		X	X	Ongoing	The County will support and promote efforts of partner agencies that provide incentive programs.
ED-8	County of San Diego	Industrial, Commercial, Municipal, Residential	Conduct inspections of inventoried existing development to ensure compliance.	Both	X	X		X		X		X	X	Ongoing	Inspections are completed on an ongoing basis as described in the JRMP and in compliance with the Permit. Twenty percent of the inventory will be inspected per year, all within 5 years.
ED-9	County of San Diego	Residential	Conduct focused residential inspections based on strategic assessments.	Both	X	X		X		X	X	X	X	Ongoing	Residential areas that are identified as contributing to nutrient loading will be selected for additional outreach and/or inspection programs. Twenty percent of the inventory will be inspected per year, all within 5 years.
ED-10	County of San Diego	Residential	Develop a residential inspections tracking program via mobile platform - miles, violations, etc.	Both	X	X		X		X		X	X	Ongoing	Residential inspections are tracking in the electronic database.
ED-11	County of San Diego	Industrial, Commercial, Municipal, Residential	Improve inspections data tracking through mobile phone applications.	Both	X	X		X		X		X	X	Ongoing	Mobile phone applications that synch to the inspections tracking system are currently in development.
ED-12	County of San Diego	Industrial, Commercial, Municipal, Residential	Enforce legal authority established for all inventoried existing development to achieve compliance.	Both	X	X		X	X	X	X	X	X	Ongoing	Legal authority will be enforced as outlined in the JRMP.
ED-13	County of San Diego and Regional Jurisdictions	Residential	Promote incentive program for BMP retrofits (e.g. water smart irrigation controllers, turf replacements programs, residential landscape evaluation program).	Both	X	X		X		X		X	X	Ongoing	The County will collaborate with and promote the efforts of partner agencies incentive programs.
ED-14	County of San Diego	Municipal	Turf replacement in Rainbow Park.	Both	X	X	X	X		X		X	X	Ongoing	The plans for this replacement are complete and work should be starting this Fiscal Year.
ED-15	County of San Diego	Equestrian Land Uses	Promote the implementation of equestrian BMPs and distribute outreach material.	Both	X	X				X	X	X	X	Ongoing	Outreach materials have been developed; identify any areas where they can be distributed.

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
Public Education and Participation (Prov E.7)															
PUB-1	County of San Diego	Industrial, Commercial, Residential	Implement a public education and participation program to promote and encourage development of programs, management practices and behaviors that reduce the discharge of pollutants in storm water prioritized by high risk behaviors, pollutants of concern, and target audiences.	Both	X	X		X	X	X		X	X	Ongoing	The County completes numerous education and public participation programs for a diverse target audiences. See JRMP.
PUB-2	County of San Diego	Residential	Educational Workshops on Integrated Pest Management, manure management and others as needed.	Both	X	X			X	X	X	X	X	Ongoing	The County completes numerous education and public participation programs for diverse target audiences. See JRMP.
PUB-3	County of San Diego	Industrial, Commercial, Residential	Collaborate with watershed partners to develop consistent messaging to targeted audiences, such as commercial residents to conserve water and reduce dry weather flows.	Both	X	X	X	X	X	X	X	X	X	Ongoing	The County completes numerous education and public participation programs for diverse target audiences. See JRMP.
PUB-4	County of San Diego	Residential, Commercial	Outreach to mobile landscaping service providers.	Both	X		X		X	X		X	X	Ongoing	Educational materials and outreach will be distributed to landscaping service providers as needed and appropriate.
PUB-5	County of San Diego	Residential	Give outreach presentations to elementary, middle, and high school students.	Both	X	X		X	X	X		X	X	Ongoing	The County completes numerous education and public participation programs for diverse target audiences. See JRMP.
Optional Jurisdictional Strategies and Schedule															
OPT-1	County of San Diego	Sewer Infrastructure	Divert persistent dry weather flows from storm drains to sewer.	Dry	X	X				X	X			Once triggered, 2-3 years	Triggers: Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) permission is granted from sewer agency; and (4) ground water or permitted discharges have been ruled out; and (5) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Contractor funding, Engineering design, Environmental review, Permits, Ongoing funding for operation/maintenance

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-2	County of San Diego and Partners	Residential, Commercial	Promote Incentive Programs: Rain Barrel, Live Turf Replacement & Outdoor Water Efficiency. Promote Incentive Programs for BMP Retrofits.	Both	X	X		X	X	X	X			Continuous, as resources allow	Triggers: Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) pilot program success; and (4) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Incentive items, Establishment of partnerships
OPT-3	County of San Diego	Onsite Wastewater Treatment Systems	Implement a program that provides rebates or incentives for pumping onsite wastewater treatment systems.	Both	X	X				X	X			Once triggered, Pilot program 1 -2 years, as needed thereafter	Triggers: Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) pilot programs have demonstrated success; and (4) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Contractor funding, Partnerships, Incentive items
OPT-4	County of San Diego	Municipal Areas	Implement a Green Streets Retrofits Program.	Both	X	X		X	X	X	X			Once triggered, 3-7 years per project; ongoing operation & maintenance thereafter	Triggers: Implementation of this strategy may be triggered on a project-by-project basis if (1) a specified interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) pilot program success; and (4) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Contractor funding, Engineering or landscaping design, Permits, Environmental review, Right of way acquisition, Ongoing funding for operation/maintenance
OPT-5	County of San Diego	Open Spaces	Flood Control Channel Rehabilitation Projects (e.g., removal of impervious lining in flood control channel and replacement with earthen or vegetated surface).	Both	X		X	X		X	X			Once triggered, 4-7 years per project; ongoing operation & maintenance thereafter	Triggers: Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) engineering design, monitoring, and outreach plans are approved; and (4) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Contractor funding, Partnerships, Engineering design, Permits, Environmental review, Right of way acquisition (if needed), Ongoing funding for operation/maintenance

Strategy Number	Geographic Extent/ Jurisdiction/ Collaboration	Sources Addressed	Strategy	Dry Weather/ Wet Weather/ Both	HPWQC	PWQCs						Implementation Schedule			Implementation Approach/Notes
					Eutrophication/ Nutrients	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	FY2017	FY2018	Future Fiscal Years	
OPT-6	County of San Diego and Regional Partners	Municipal Areas	Identify candidate areas of existing development for stream, channel, and/or habitat rehabilitation projects and facilitate implementation of such projects.	Both	X		X	X		X	X			Once triggered, 4-7 years per project; ongoing operation & maintenance thereafter	Triggers: Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined by the County of San Diego through adaptive management that implementation is necessary; and (3) all of the necessary resources have been secured. Resources include: Staff availability, Grant funding or alternative source, Contractor funding, Partnerships, restoration/rehabilitation designs approved, Environmental permits issued, CEQA/NEPA environmental review, and Ongoing funding for maintenance and monitoring.

The subsections below highlight some of the jurisdictional strategies, listed in **Table 4-14**.

4.2.2.2.1 Illicit Discharge Detection and Elimination [Permit Provisions D.2 and E.2]

4.2.2.2.1.1 Address Impacts of Sewers and Septic Systems

Sanitary sewer overflows (SSOs) are typically episodic events but can contribute to nutrient loads if they are not addressed promptly. Although overflows can happen during wet weather, they typically occur most often during dry weather. SSOs may occur from private sewer laterals and from the publicly owned sanitary system when blockages occur due to roots, grease, or other debris.

In addition to SSOs, faulty septic or Onsite Wastewater Treatment Systems (OWTS) can be a source of nutrients in this watershed area. The Local Agency Management Program (LAMP) describes San Diego County procedures for OWTS requiring corrective action. Within 24 hours of a complaint or other notification of a failing OWTS, the San Diego County Department of Environmental Health (DEH) will complete an investigation to determine the validity of the complaint. The LAMP provides DEH with the authority to require action to repair any OWTS within a reasonable time frame. If corrective action is not completed, enforcement will escalate, which may include condemnation of the structure.

4.2.2.2.1.2 Inspections and Enforcement of Illicit Discharges and Connections

Many types of illegal discharges contribute to nutrient loading in stormwater discharge and receiving waters. Illegal connections that convey these discharges are equally problematic. These challenges are typically associated with dry weather, transient in nature, and have been a focal point for the Copermittees' stormwater programs for many years. Full scale elimination of illegal discharges is challenging and requires a societal change in the way water is managed.

The County of San Diego will implement an active field program to better locate and abate illicit dry weather discharges. Potential dry weather discharges will be evaluated through inspections of MS4 outfalls discharging to receiving waters. Staff will spend time present in unincorporated communities identifying nuisance anthropogenic flows and addressing them through appropriate education and enforcement strategies. County of San Diego staff members have been trained to identify and report illicit discharges and illegal connections during required annual storm water training; this training has been updated to reflect recent Permit changes.

4.2.2.2.2 Development Planning [Permit Provision E.3]

4.2.2.2.2.1 Equine Facility BMPs, Manure Management, and Equine BMP Manual Updates

The Lower SMR Subwatershed contains a significant amount of rural residential land uses, where lots tend to be larger and domestic livestock are more common. Several programs are implemented that address domestic animals as sources of nutrients.

If not applied properly, manure can be a significant source of nutrient loading when used as fertilizer. Manure re-use is addressed through several existing programs, in conjunction with existing development requirements. Examples include:

- Composting areas must be located in a fashion so as to prevent runoff to the MS4 or receiving waters.

- Existing development inspections programs provide oversight, outreach, and enforcement where necessary to ensure proper storage and re-use of manure.
- IDDE, monitoring, and source tracking programs are in place to detect discharges and identify sources where manure re-use may be contributing to water quality problems related to nutrient loading.

An effective source control program promotes an inventory and frequent inspection of horse ranches, livestock areas, kennels and other pet service areas. Community outreach tools include education materials that stress manure and wash water management, directing drainage away from and/or around exposed stalls, horse health, and WMA awareness. These BMPs address both commercial and private facilities.

The County of San Diego Equine Best Management Practices Manual has been developed as a resource for horse owners and facilities to manage stormwater runoff. This manual contains helpful information for manure management, dirt access roads and trails, arenas and paddocks, stockpiles, horse wash rack drains, vehicle maintenance, housekeeping, site design, exclusionary fencing, pest management, training and education.

4.2.2.2.2.2 BMP Design Manual Updates and Training

The BMP Design Manual requirements apply to residential, commercial, industrial, educational, and transportation land uses. The Manual guides applicants through the design and submittal process to ensure the necessary stormwater features are being implemented. Project designs must show runoff being infiltrated or else treated by structural BMPs, such as bioretention facilities, planter boxes, filters, settling ponds, or constructed wetlands.

The BMP Design Manual for new development and redevelopment was updated in FY16 and training was provided to County of San Diego staff, followed by the development industry. One-time land development workshops were held to educate the development community on updated requirements, particularly as they pertain to priority sources of bacteria, nutrients, and other pollutants, such as residential areas and commercial areas including nurseries and eating/drinking establishments.

4.2.2.2.3 Construction Management [Permit Provision E.4]

Although development in this region of the watershed is limited, construction sites have the potential to contribute to nutrient loading primarily through ineffective erosion control that can lead to phosphorus-borne sediment entering the receiving water.

The agencies have been implementing construction stormwater programs for several Permit terms. Over this time, agency staff and the construction community have become well trained in construction stormwater management. Additional oversight is required per the State Construction General Permit (Order 2009-0009-DWQ) for sites greater than one acre. With this amount of focus, the limited sources of nutrients related to construction are well addressed via the existing Permit requirements. For this reason, the agencies will focus on the baseline programs as required under the Permit.

For active construction areas, the County routine enforcement measures include Administrative

Warnings and Notices of Violation. Public works projects use construction plans, specifications, and Stormwater Pollution Prevention Plans to effectively eliminate or control pollutant discharge

through stormwater. Adherence with contract provisions is confirmed by inspection staff and enforced using standard payment provisions, liquidated damage clauses, and other means.

4.2.2.2.4 Existing Development Management [Permit Provision E.5]

The Existing Development Management Program addresses a variety of sources including commercial/industrial, residential, and municipal areas and activities. The County of San Diego has an inspection program that addresses each of these sources. Due to the prevalence of rural residential land in this area, jurisdictional strategies will focus on residential inspections to help reduce irrigation runoff and nutrient loading to the receiving water.

4.2.2.2.4.1 Residential Inspections

The "education first" approach is a key component in the County's routine enforcement process within existing residential areas. County staff are also required to inspect structural BMPs and respond to complaints regarding structural BMP performance. Advisory letters, verbal warnings, CARs, and Clean-up and Abatement Notices (through which the County cleans or repairs the structural BMP and then charges the responsible party) are all routinely used as follow up measures, if necessary. As field staff conduct investigations, they maintain records and a database of relevant information for each incident. This information is entered into a database that is used for annual reports submitted to the Regional Water Board.

Educational outreach by the County is developed and implemented based on the following four objectives:

1. Teaching basic awareness;
2. Adapting education to specific target audiences;
3. Clearly describing specific responsibilities under the Watershed Protection Ordinance; and,
4. Providing instruction to successfully implement BMPs, with an emphasis on pollution prevention.

For the residential and general public audiences, the County's educational outreach program, as described in the JRMP, utilizes a multi-media approach. Media types may include print materials, television, radio, websites, billboards, and promotional items. Through joining efforts with the County Water Authority, the County of San Diego has been and continues to work to collaborate on efforts to reduce water use and over-irrigation. Messages and promotional materials have been tailored to promote the use of native or drought-tolerant plants.

Irrigation runoff reduction programs can also be integrated with BMPs that encourage landscaping and gardening practices that reduce the load of fertilizers and chemicals that enter in stormwater, such as integrated pest management, reduction of fertilizer and pesticide use, xeriscaping and turf conversion.

4.2.2.2.4.2 Turf Replacement at Rainbow Park

To reduce irrigation runoff and other dry weather pollutant generating activities from County Parks, the County of San Diego is replacing 95,000 square feet of existing lawn in Rainbow Park with synthetic turf and a sand infill drainage system. This retrofit will begin in 2017, with construction estimated to be completed in 2018.

4.2.2.2.4.3 Rainbow Creek Nutrient Reduction and Management Plan

The Rainbow Creek Nutrient Reduction and Management Plan (NRMP), required by Section B.2 of the Permit, was completed in 2016 and outlines several waste control and cleaning practices for County-responsible sources. Management practices for irrigation, nutrient control, and erosion and runoff are recommended for agricultural operations. The County of San Diego's Department of Agriculture, Weights, and Measures (AWM) is authorized to inspect commercial nurseries and greenhouse facilities and conduct follow up inspections if deficiencies are found.

AWM's inspection frequencies are prioritized based on the facility's assigned threat to water quality, as determined using the methodologies outlined in the County's JRMP, Section 5.2.4. AWM annually inspects all facilities that have been designated as a high threat to water quality. The goal for each inspection is to ensure compliance with the County's Watershed Protection Ordinance. For locations where non-compliance is observed at the time of the inspection, AWM follows the Enforcement Response Plan as described in the JRMP, Section 9.0 and in Section 4.2.2.2.5 below. Consistent with the education first approach taken across the stormwater program, AWM often provides contact information for various organizations that can provide assistance with BMP implementation at agricultural operations, such as Mission Resource Conservation District, Natural Resource Conservation Service and University of California Cooperative Extension Office.

4.2.2.2.4.4 Sustainable Landscapes Retrofit Program

The Sustainable Landscapes Retrofit Program is designed to encourage landscape retrofits to reduce the amount of potable water applied to urban landscapes and minimize pollutant infiltration to local waterbodies. Through an Integrated Regional Water Management Program (IRWMP) grant awarded using state of California Proposition 84 funds, the County of San Diego in concert with other agency and non-government partners is also developing a Sustainable Landscapes Retrofit Program. The Sustainable Landscapes Retrofit Program consists of an integrated set of landscaping practices, including stormwater capture and use, LID and potable water conservation that will help property owners retrofit their high water-use landscaping for more sustainable ones. The program targets residential-scale urban landscapes, and is a collaborative effort among three public agencies. Multipollutant benefits of the program include reduction in nutrients and bacteria from residential areas, nurseries, and greenhouses. The program leads to benefits to water quality improvement and reduced cost for the Copermittees. Reductions in cost are realized from reductions in water use, green waste, labor, fertilizers, pesticides, and carbon dioxide emissions. Target areas include municipal fixed facilities; industrial and commercial facilities; construction sites; residential; general public; land development and redevelopment; streets and parking facilities.

4.2.2.2.4.5 Designate a Minimum Set of BMPs Required for Existing Development Inventories

The County of San Diego has established a set of minimum BMPs to support their jurisdictional strategy implementation. These BMPs are presented in **Table 4-15**.

4.2.2.2.5 Enforcement Response Plans [Permit Provision E.6]

As described in the County of San Diego's Enforcement Response Plan (ERP), a wide range of enforcement 'tools' can be implemented to abate illicit discharges and facilitate compliance.

The primary objective of the ERP is to promote voluntary compliance with applicable ordinances and the NPDES permit provisions. In cases of non-compliance, the ERP provides County staff with several enforcement tools to ensure a return to compliance in a timely manner while following due process. While emphasizing education as the primary means of achieving compliance, the County also has the necessary authority and procedures in place to investigate and enforce in cases of continued non-compliance. In the event that a violation or potential violation may endanger health or the environment, the County may forego the "education first" approach and proceed immediately to more stringent enforcement measures.

4.2.2.2.6 Public Education and Participation [Permit Provision E.7]

Education and outreach programs are implemented to provide the public with resources and incentives to accomplish projects and practices that protect and improve water quality throughout the WMA. The County of San Diego provides manuals for landscaping and BMP design that, if implemented, reduce dry weather flows to the MS4 and ultimately to receiving waters. These manuals include the LID Handbook, the Standard Urban Stormwater Mitigation Plan (SUSMP) (County of San Diego, 2012), the Hydromodification Management Plan (HMP) (County of San Diego, 2011), and the BMP Design Manual (County of San Diego, 2016).

Materials for education and outreach have been developed to focus on prevention of discharges to the MS4 and reduction of pollutants reaching receiving waters. Specific handouts have been created related to over-irrigation that may be distributed to property owners in the WMA. Additionally, promotional items are often distributed and may include pens, pencils, magnets, and rulers, as well as more behavior-specific items including packages of California poppy seeds to promote the use of native or low maintenance plants. All items contain stormwater messages and the County of San Diego Stormwater Hotline and Project Clean Water website. Outreach materials are distributed by County staff during community events, displayed in kiosks at appropriate locations, and supplied to partner organizations to distribute at their facilities.

The County will continue to sponsor workshops for specific target audiences and pollutants of concern, including some that address nutrients such as manure management and composting for horse owners and animal facilities; integrated pest management and gardening workshops for residents interested in gardening and more sustainable landscape practices; and rain water harvesting classes to encourage rainfall capture from roofs for landscape use.

Table 4-15. Minimum BMPs Supporting Jurisdictional Strategy Implementation for the Lower SMR Subwatershed

Best Management Practice Watershed	Pollutant Sources								HPWQC
	Residential	Commercial	Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries	Horse Ranches	Other Agriculture	Open Space	Nutrients
1. Eliminate illicit connections to the municipal separate storm sewer system (MS4).	●	●	●	●	●	●	●		●
2. Eliminate illicit non-storm water discharges.	●	●	●	●	●	●	●	●	●
3. Properly dispose of process and wash water.	●	●	●	●	●	●	●		●
4. Properly dispose of vehicle and equipment wash water/eliminate the discharge of vehicle and equipment was water.	●	●	●	●	●	●	●		
5. Properly dispose of water from fire sprinkler maintenance activities	●	●	●	●	●	●	●		
6. Eliminate pumped groundwater, foundation and footing drain discharges.	●	●	●	●	●	●	●		●
7. Minimize rising groundwater, diverted stream flows, uncontaminated groundwater infiltration, springs, riparian habitat/wetland flows, potable water sources, and foundation/ footing drain discharges.	●	●	●	●	●	●	●	●	●
8. Protect unpaved areas, including landscaping, from erosion using vegetation or physical stabilization.	●	●	●	●	●	●	●	●	●
9. Regularly clean parking lots.	●	●	●	●	●	●	●		
10. Implement good housekeeping to keep site free of trash and debris.	●	●	●	●	●	●	●	●	●
11. Provide and maintain secondary containment to catch spills when storing potential liquid pollutants in outdoor areas.	●	●	●	●	●	●	●		●
12. Properly store and dispose of hazardous substances.	●	●	●	●	●	●	●		●
13. Cover, contain, and/or elevate materials stored outside that may become a source of pollutants in storm water or non-storm water.	●	●	●	●	●	●	●		●
14. Label containers to prevent mishandling of hazardous materials and other potential pollutants.	●	●	●	●	●	●	●		●

Best Management Practice Watershed	Pollutant Sources								HPWQC
	Residential	Commercial	Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries	Horse Ranches	Other Agriculture	Open Space	Nutrients
15. Develop a written plan that identifies appropriate BMPs, including spill response, and includes procedures for proper implementation.	●	●	●	●	●	●	●		●
16. Prevent or capture liquid leaks from vehicles and equipment.	●	●	●	●	●	●	●		
17. Maintain a readily accessible spill cleanup kit that is appropriate for the type of material stored.	●	●	●	●	●	●	●		●
18. Immediately clean up spills.	●	●	●	●	●	●	●		●
19. Temporarily protect MS4s from non-storm water discharges while conducting activities that have the potential to result in a discharge.	●	●	●	●	●	●	●	●	●
20. Implement a pollution prevention system for uncovered outdoor sources of pollutants.	●	●	●	●	●	●	●	●	●
21. Train appropriate employees on storm water pollution prevention.	●	●	●	●	●	●	●	●	●
22. Keep trash/waste storage areas free of exposed trash, sediment, and debris.	●	●	●	●	●	●	●	●	●
23. Protect waste storage areas from contact with storm water and non- storm water flows on to the property.		●	●	●	●	●	●	●	●
24. Eliminate irrigation runoff.	●	●	●	●	●	●	●		●
25. Eliminate nursery irrigation discharges.	●	●	●		●				●
26. Properly dispose of discharges from swimming pools, spas, fountains, reflective pools, ponds, and filter backwash.	●	●	●	●					●
27. Control air conditioning condensation discharges.	●	●	●	●	●	●			●
28. Eliminate floor mat cleaning discharges.	●	●	●	●					●
29. Regularly clean and maintain structural BMPs and LID installations to ensure proper performance.	●	●	●	●	●	●	●		●

Best Management Practice Watershed	Pollutant Sources								HPWQC
	Residential	Commercial	Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries	Horse Ranches	Other Agriculture	Open Space	Nutrients
30. Keep storm drain inlets and under drains free of sediment, trash, and debris.	●	●	●	●	●	●	●		●
31. Properly manage pesticides and fertilizers.	●	●	●	●	●	●	●		●
32. Implement controls to prevent pollution from exposed outdoor work areas.	●	●	●	●	●	●	●		●
33. Drain fluids from inoperable vehicles and store or dispose of appropriately.	●	●	●	●	●	●	●		
34. Provide pollution prevention signage for storm drains.	●	●	●	●	●	●	●		●
35. Properly store and dispose of green waste.	●	●	●	●	●	●	●		●
36. Manage animal waste and animal washing in a manner that prevents transport of wastes and wash water off-site.	●	●	●	●	●		●		●

4.2.2.3 Optional Strategies

Optional jurisdictional strategies include those that the Copermittees may implement if necessary to achieve interim and final numeric goals. Implementation of the optional strategies will be contingent on circumstances supported by the need for the additional effort, the cost/benefit as compared to other options and strategies, and the availability of funding. Optional jurisdictional strategies for the County of San Diego in the Lower SMR Subwatershed are listed above in **Table 4-14**. The subsections below summarize the optional strategies, or combinations of optional strategies.

4.2.2.3.1 Dry Weather Flow Diversion

Diverting persistent dry weather flows to sanitary sewers reduces nutrient loading to the receiving water. This strategy addresses nuisance dry weather flows from the MS4 and pollutants from roads, streets, and parking lots. Structural BMPs will also be implemented within the County of San Diego's jurisdiction. The County of San Diego will take into account the locations of existing structural controls when considering future implementation efforts and potential locations for structural controls.

Implementation of this strategy may be triggered if:

1. An interim goal has not been met;

2. It has been determined by the County of San Diego, through adaptive management, that implementation is necessary;
3. Permission is granted from wastewater collection agency;
4. Permitted discharges have been ruled out; and
5. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative source, contractor funding, engineering design, environmental review, permits, ongoing funding for operation/maintenance.

4.2.2.3.2 Promote Incentive Programs for BMP Retrofits

Another tactic for addressing the source of nutrient loading in this area is the increased promotion and support of incentives targeted to promote water conservation and landscape retrofits through partner agencies (including Metropolitan Water District, local water districts, and the San Diego County Water Authority). Examples of these incentive programs include payments for things such as turf replacement, sprinkler head nozzle replacements, smart irrigation controllers, rain barrels, etc. These incentive programs can be an important tool in creating change at the individual level and could be promoted until resources are depleted. Programs that support landscape retrofits will target sources of wet and dry weather flows that can mobilize nutrients, particularly those associated with residential areas as well as roads, streets, and parking. The Sustainable Landscapes Retrofit Program is also currently being implemented to encourage landscape retrofits at nurseries and greenhouses, as well as residential areas. The Sustainable Landscapes Retrofit Program is discussed in greater detail in **Section 4.2.2.2.4**.

Implementation of this strategy will be triggered if:

1. An interim goal has not been met;
2. It has been determined by the County of San Diego through adaptive management that implementation is necessary;
3. Pilot program success and;
4. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative funding source, incentive items, and establishment of partnerships.

4.2.2.3.3 Septic System Rebate Programs

Many properties in this area operate onsite wastewater treatment systems. Improperly maintained OWTS can be a source of nutrients. If funding were available, a Septic System Rebate Program could be implemented. This rebate program would be designed to target nutrient loading by promoting frequent inspection and pumping, which can prevent septic system failures. Additional resources to educate property owners of recommended maintenance activities and preventative measures, such as what not to put into the system and how to avoid overloading their residential septic systems, could be developed and made available. Rebates would be available on a first-come, first serve basis as funding allows.

Rebate and inspections programs as an optional jurisdictional strategy would be triggered if:

1. An interim goal has not been met;

2. It has been determined by the County of San Diego through adaptive management that implementation is necessary;
3. Pilot programs have demonstrated success; and
4. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative source, contractor funding, partnerships, and incentive items.

4.2.2.3.4 Green Streets Retrofit Program

The County of San Diego utilizes LID projects and green street designs to effectively reduce flows during storm events and to reduce nutrient concentrations by retrofitting impervious areas. Green infrastructure aims to incorporate elements found in natural areas into the road right-of-way to provide water quality and community benefits. Green streets, in particular, can consist of multiple BMP types implemented in a linear manner within the road right-of-way. Placing BMPs within the right-of-way provides an additional opportunity to treat urban storm water runoff, attenuate peak flow, and reduce discharge volume while improving community pride, land value, and habitat quality. Green streets also provide the added benefit of treating runoff from both the roadway and contributing parcel.

This strategy would be implemented if:

1. An interim goal has not been met;
2. It has been determined by the County of San Diego, through adaptive management, that implementation is necessary;
3. Pilot program success; and
4. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative funding source, contractor funding, engineering or landscaping design, permits, environmental review, right of way acquisition, and ongoing funding for operation/maintenance.

4.2.2.3.5 Flood Control Channel Rehabilitation Projects

Examples of potential rehabilitation projects include partial or total removal of impervious lining in the flood control channel and replacement with an earthen or vegetated surface. These projects can result in nutrient and sediment load reductions and restoration of aquatic habitat and vegetation. They may also provide educational opportunities and lead to greater public understanding of water quality protection and improvement actions. Rehabilitation projects are expected to address nutrient loading in receiving waters.

Implementation of this strategy may be triggered if:

1. An interim goal has not been met;
2. It has been determined by the County of San Diego, through adaptive management, that implementation is necessary;
3. Engineering design, monitoring, and outreach plans are approved; and
4. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative source, contractor funding, partnerships, restoration / right of way acquisition, California Environmental Quality Act (CEQA)/National Environmental Policy

Act (NEPA) environmental review, environmental permits issued, and ongoing funding for maintenance and monitoring.

4.2.2.3.6 Stream Restoration Projects

Increased runoff volumes and velocities from natural wet weather events and increased urban development can result in erosion of stream banks and channels and degrade or alter natural systems. Erosion can result in large quantities of sediment and sediment-bound pollutants such as phosphorus entering the water column and traveling downstream, where it can contribute to nutrient loading in the SMR Estuary. A stream restoration project could be designed to reduce nutrient loading and is expected to have supplemental reductions to bacteria and sediment.

The stream restoration remedy includes the following proposed options, as funds are available and pending approval of environmental documents, obtaining permits, and the feasibility of effectiveness:

- Widening or modifying the impaired creek channel to disperse and slow flow to increase residence time and nutrient uptake.
- Re-sloping streambanks to reduce erosion and Total Suspended Solids (TSS) and nutrient loading downstream.
- Streambank stabilization by revetments, log cribs, groins, or gabions reduce erosion and TSS and nutrient loading downstream.
- Floodplain restoration and reconnection with the stream course to increase retention time and groundwater recharge.
- Restored native basins to temporarily capture and reduce flow and promote nutrient uptake and groundwater recharge.
- Refurbishment of existing basins for desilting and groundwater recharge.
- Replacing invasive vegetation species with native vegetation that has increased nutrient uptake.

Implementation of this strategy may be triggered if:

1. An interim goal has not been met;
2. It has been determined by the County of San Diego, through adaptive management, that implementation is necessary; and
3. All of the necessary resources have been secured. Resources include staff availability, grant funding or alternative source, contractor funding, partnerships, approved restoration/rehabilitation designs, CEQA/NEPA environmental review, environmental permits issued, and ongoing funding for maintenance and monitoring.

4.2.3 Optional WMA Strategies

The Copermittees and the City of Menifee have identified multiple coordinated efforts (i.e., optional regional or multijurisdictional WMA strategies) to be implemented to address eutrophication impacts and nutrient loading within the SMR watershed. The optional WMA strategies differ from the optional jurisdictional strategies in that they are a coordinated effort

amongst two or more jurisdictions working collaboratively, at a regional, WMA, or multi-jurisdictional level within the SMR WMA towards common goals within the watershed. Collaboration potentially increases efficiency and effectiveness in addressing sources through economies of scale (e.g., watershed-wide outreach approaches or incentive programs to address over-irrigation, in-stream rehabilitation to reduce eutrophication within waterbodies). The coordinated efforts are summarized in **Table 4-16**.

As part of the five-year assessment process, implementation of strategies will be evaluated against progress to goals. Where interim goals are met and the current implementation approach is determined to be effective enough to achieve the next interim or final goal, Copermittees and the City of Menifee may adjust current strategies, but will likely not implement optional WMA strategies. Where interim goals are not achieved, and/or it is determined to be unlikely that current implementation levels will achieve future interim or final goals, optional WMA strategies may be triggered and implemented as resources allow. Implementation of the optional WMA strategies will be contingent on circumstances supported by the need for the additional effort, the expected efficiency and effectiveness of the strategy as compared to other options and strategies, and the availability of funding. The process to trigger the watershed strategies are specific to the individual WMA strategy, and are largely dependent on necessity and availability of funding. Each of the WMA strategies is included as an option moving forward for all jurisdictions; however, specific projects for implementation may only include a subset of the jurisdictions, depending on the applicability of the WMA strategy to the jurisdiction.

Table 4-16. Collaborative WMA Strategies for the SMR WMA

Optional WMA Strategy	Implementation Timeframe/ Schedule	RCFCWCD	County of Riverside	County of San Diego	City of Menifee	City of Murrieta	City of Temecula	City of Wildomar	Triggers	Resources	Pollutant Sources	HPWQC	Priority Water Quality Conditions						
												Eutrophication (Nutrients)	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	Industry
Incentive programs to reduce non-stormwater and stormwater runoff (e.g., drought tolerant landscaping, rain barrel program, turf replacement).	Implemented starting in the following fiscal year after triggered.	•	•	•	•	•	•	•	Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined through adaptive management that implementation is necessary and that this approach would help to address sources of nutrient loading; and (3) all the necessary resources have been secured.	(1) Willing partners (e.g., Water Districts, other municipalities); (2) funding necessary to contribute to a program; (3) if resources are unavailable, implementation would be contingent on receipt of grant funding	Sources within upstream catchment area (to be determined)	•	•	•	•	•	•	•	•
Regional dry weather inspector(s): Inspect areas watershed-wide for anthropogenic sources of dry weather flow, gather Permit-required information, conduct outfall screening, follow a developed SOP, and alert responsible Copermittee when issues are observed.	Implemented within two fiscal years after triggered.	•	•			•	•		Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined through adaptive management that implementation is necessary and that this approach would help to address sources of nutrient loading; and (3) all the necessary resources have been secured.	(1) Funding for one full time position within an agency in the watershed or contract supported by other Copermittees within the watershed (2) Each Copermittee would need available staff resources to respond to identified problems and proceed with enforcement as necessary	Dry weather flows from targeted areas	•	•	•	•	•	•	•	•
In-stream strategies, including watercourse rehabilitation to provide natural uptake of nutrients, increase shading, or modify physical factors to reduce algal growth.	Allow 2-5 years for design, permit, and construction once triggered.	•	•	•	•		•		Implementation of this strategy may be triggered if (1) an opportunity for a project is identified that would effectively address problems within the watershed; and (2) an interim goal has not been met; and (3) Copermittees with jurisdiction are willing participants in the project; and (4) all necessary resources and permits have been secured.	A stream restoration project would require the following resources: 1) Studies to identify suitable sites; 2) Evaluation of feasibility; 3) Engineering design plans; 4) Capital Improvement Program funding secured; 5) Land acquisition and/or private-public partnership agreements (as necessary); 5) Construction contract bid/award; 6) Project construction; 7) Adequate resources for operation and maintenance	Sources within upstream catchment area (to be determined)	•	•	•	•	•	•	•	•
Regional dry weather retrofits or incentives for retrofits for existing development to reduce/eliminate dry weather flows.	Allow 2-5 years for design, permit, and construction once triggered.	•	•				•		Implementation of this strategy may be triggered if (1) an interim goal has not been met; and (2) it has been determined through adaptive management that implementation is necessary; and (3) all the necessary resources have been secured.	Retrofit program would require the following resources: 1) In-field evaluation of suitable sites for infiltration or diversion to sanitary sewer; 2) Evaluation of feasibility; 3) Engineering design plans; 4) Capital Improvement Program funding secured; 5) Land acquisition and/or private-public partnership agreements (as necessary); 5) Construction contract bid/award; 6) Project construction; 7) Adequate resources for facility operation and maintenance	Dry weather flows from targeted areas	•	•	•	•	•	•	•	•

Optional WMA Strategy	Implementation Timeframe/ Schedule	RCFCWCD	County of Riverside	County of San Diego	City of Menifee	City of Murrieta	City of Temecula	City of Wildomar	Triggers	Resources	Pollutant Sources	HPWQC	Priority Water Quality Conditions						
												Eutrophication utrients)	Recreation	Physical Habitat	Toxicity	Nuisance (Trash)	Water Supply	Agricultural Supply	Industry
Coordinate with Integrated Regional Water Management (IRWM) regional water managers to plan for and implement water quality improvement projects (retrofits, stream rehabilitation, or other projects) that will address nutrients and/or dry weather flows.	As triggered	•		•					Participation as stakeholder in IRWM program will occur, as needed and if funded, to promote applicable project adoption in the SMR WMA.	Individual projects and further participation in grant funding offered through IRWM assessed on case-by-case basis.	Sources within upstream catchment area (to be determined)	•	•	•	•	•	•	•	•
Participate in Santa Margarita River Watershed Nutrient Initiative - Stakeholder Group as a collaborative effort to reduce nutrients and dry weather flows.	Ongoing	•	•	•		•	•	•	Ongoing participation. This work is a follow-on effort to the 2006 San Diego Lagoons Investigative Order (R9-2006-0076; Lagoon Order) and subsequent work plan developed jointly by the Regional Water Board and WMA stakeholders.	Funding for staff support within an agency or contract supported by other Copermittees within the watershed	Sources within upstream catchment area (to be determined)	•							

The subsections below summarize the WMA strategies, or combinations of collaborative WMA strategies, listed in **Table 4-16**.

4.2.3.1 Santa Margarita River WMA Nutrient Initiative Group

Copermittees will continue to participate in the SMRNIG efforts so long as that group is active. The SMRNIG is further described in **Chapter 2**. SMRNIG efforts include evaluation of implementation scenarios, conducting studies, and providing a forum for development of collaborative watershed strategies with other stakeholders.

4.2.3.2 Permitted Flow Assessment

The Copermittees will also implement additional strategies designed to gather data and improve their understanding of conditions in the watershed. Assessments and evaluations of permitted non-stormwater discharges and a watershed management area analysis are currently planned for implementation and are described below. Permitted flow assessments are anticipated to begin upon acceptance of the WQIP.

To address MS4s with anthropogenic dry-weather flow, the Copermittees will conduct an assessment of flows from MS4 outfalls to determine which flows should be addressed by the Copermittee, and which flows are permitted, or required to be permitted by others, or those flows originating from lands outside the Copermittees' jurisdiction (e.g., Tribal Lands). The assessment will include the following components:

- Work with the Regional Water Board to conduct an inventory of permitted discharge and recycled water conveyances (purple pipes);
- Complete an inventory of natural sources (rising groundwater, springs, etc.); and
- Conduct a flow and load characterization.

As a component of the assessment, a monitoring plan to identify permitted discharges will be developed within the Monitoring and Assessment Program (Permit Provision D). The permitted flow assessment will be initiated during FY 2017/2018, and completed during FY 2020/2021.

4.3 WATERSHED MANAGEMENT AREA ANALYSIS

The Copermittees within the Middle and Lower SMR Subwatersheds have developed a Watershed Management Area Analysis (WMAA), which is an optional task for the purpose of developing watershed-specific requirements for structural BMP implementation. The WMAA is a watershed-scale analysis that identifies important characteristics, such as hydrologic process categories and stream descriptions. The final output of the analysis includes geographic information system (GIS) layers that Copermittees may use to identify candidate projects as offsite alternative compliance options. The WMAA also develops analyses and information to support exemptions from the on-site hydromodification management BMP requirements. Per Permit Provision B.3.b.(4)(a), the WMAA includes the following:

(i) A description of dominant hydrologic processes, such as areas where infiltration or overland flow likely dominates;

(ii) A description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral;

(iii) Current and anticipated future land uses;

(iv) Potential coarse sediment yield areas; and

(v) Locations of existing flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins.

The WMAA also includes a list of candidate projects that could be used as alternative compliance options for Priority Development Projects (PDPs). The WMAA is included as **Appendix 4B** and will be incorporated into the WQIP as part of the adaptive management process.

The Permit allows Copermittees to develop a program as part of their overall JRMP that potentially allows development projects to participate in offsite alternative compliance projects that yield greater overall water quality benefit to the WMA. The Copermittees may use the data generated from the characterization analyses indicated above for two purposes:

(1) To identify candidate projects that could potentially be used as offsite alternative compliance options in lieu of satisfying full onsite retention, biofiltration, and hydromodification management control requirements as is required for PDPs.

(2) To identify and/or prioritize areas where it is appropriate to allow certain exemptions from onsite hydromodification management BMPs.

The updated WMAA builds upon work completed in the 2015 San Diego County Regional Watershed Management Analysis. (http://www.projectcleanwater.org/watershed-management-area-analysis-wmaa) The San Diego analysis developed the tools and mapping for the Lower SMR Subwatershed. This analysis extends into the Middle SMR Subwatershed, and studies hydromodification susceptibility of the SMR to the Pacific Ocean. The WMAA will develop WMA-specific requirements for structural BMPs and identify candidate projects related to hydromodification, stream restoration, or structural BMPs. The elements of the analysis are specific to all Copermittees within the SMR Region, which includes County of Riverside, RCFCWCD, City of Wildomar, City of Murrieta, City of Temecula, and County of San Diego.

5 Monitoring and Assessment Program

Chapter 5 outlines procedures to support assessment of progress toward numeric goals and schedules, progress addressing eutrophication impacts and nutrient loading, and each Copermittee's overall efforts to implement the WQIP. In conducting previous NPDES MS4 Permit required monitoring and by participating in various regional monitoring efforts over the past 20 years, the Copermittees have established water quality monitoring stations throughout the SMR WMA. A select number of existing monitoring stations will continue to be monitored. In addition, new monitoring stations to fulfill requirements not contained in previous versions of the Permit have been identified. The quantity and required characteristics of these new monitoring stations are described under the applicable program component in the sections below. The reporting year for the Monitoring and Assessment Program (MAP) extends from October 1st to September 30th of the following year.

5.1 SMR WMA MAP DESCRIPTION

The SMR WMA MAP includes the Receiving Water Monitoring Program, the MS4 Outfall Discharge Monitoring Program, Special Studies, and Assessment Program. The SMR WMA MAP is designed to determine the following:

- The long-term receiving water trends and whether conditions in receiving waters are improving;
- If urban runoff is contributing to exceedances of WQOs and impacting beneficial uses of receiving waters;
- Pollutant sources and/or stressors;
- The effectiveness of the Copermittees' JRMP toward effectively prohibiting non-storm water discharges into the MS4 and reducing pollutants in stormwater discharges from their MS4s to the MEP; and
- Progress of the water quality improvement strategies implemented as part of this WQIP toward achieving numeric goals and schedules, addressing the HPWQC, and achieving compliance with the discharge prohibitions of the Permit.

5.2 SMR WMA MAP MONITORING QUESTIONS

The SMR WMA MAP is designed to evaluate and address current and/or potential water quality issues in the SMR WMA that may be impacted by discharges of urban runoff from the MS4. The data collected under the MAP will be used to assess the effectiveness of strategies and progress to numeric goals for the WMA. The SMR WMA MAP is designed with the overall goal of answering the following monitoring questions in support of the numeric goals for the WMA presented in **Chapter 4**:

- How much has total nitrogen and total phosphorus loading been reduced in the SMR watershed?
- How much has non-storm water flow been reduced at Copermittee outfalls?

- How much has total nitrogen and total phosphorus loading been reduced at Copermittee outfalls?
- Are there sources of pollutants outside of Copermittee control causing exceedances of targets?

5.3 GENERAL SCOPE OF MONITORING

The monitoring component of the SMR WMA MAP includes the following programs:

1. **Receiving Water Monitoring**
    - Wet Weather Receiving Water Monitoring Program
        - Field Observations and Monitoring, Analytical, and Toxicity
    - Dry Weather Receiving Water Monitoring Program
        - Field Observations and Monitoring, Analytical, Toxicity, Bioassessment, and Hydromodification
    - Regional Monitoring Programs
        - Storm Water Monitoring Coalition (SMC) Regional Monitoring
        - Southern California Bight (Bight) Regional Monitoring
    - Sediment Quality Monitoring Program
    - TMDL Monitoring
2. **MS4 Outfall Monitoring**
    - Wet Weather MS4 Outfall Discharge Monitoring Program
        - Field Observations and Monitoring, Analytical
    - Dry Weather MS4 Outfall Discharge Monitoring Program
        - MS4 Outfall Discharge Field Screening Monitoring
        - Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring (including field observations and analytical)
3. **Special Studies**
    - WMA Special Study
    - San Diego Region Special Study

Table 5-1 provides a summary of the major monitoring programs. All monitoring activities are intended to be conducted in general conformance with the recommended protocols provided by the SWAMP. Monitoring program elements are described in the sections to follow, and additional program details for individual monitoring programs are discussed in **Appendix 5A**. The SMR WMA MAP will be reviewed annually, as necessary, and any updates will be submitted to the Regional Water Board as part of the WQIP Annual Report.

Receiving water monitoring will consist of time-weighted or flow-weighted composite samples collected by automated samplers, in addition to grab samples, field measurements, visual

observations, and bioassessment. Wet weather MS4 outfall monitoring will use time-weighted or flow-weighted composite sampling in wet weather, and grab sampling for appropriate analytes. Dry weather MS4 outfall monitoring will generally use a grab sampling approach. When feasible and required, a regional watershed approach is implemented for elements of the monitoring program to enhance consistency of monitoring data within the San Diego Region. Monitoring of wet weather and dry weather flows is included in this SMR WMA MAP. Available USGS gauging station data may be used for continuous flow measurements as applicable. Monitoring events will be coordinated by the Copermittees, and/or with consultants authorized to monitor on behalf of the Copermittees.

Table 5-1. Summary of Monitoring Programs

SMR WMA MAP Component	# Events	Sample Type	Analyses	Permit Provision
Wet Weather Receiving Water Monitoring Program (**Section 5.3.1.1**)	Three per permit term according to sampling schedule[1]	Field Observations	Location, date, duration of storm event, rainfall estimate of storm event, duration between storm event sampled and the end of previous measurable (> 0.1 inch rainfall) storm event. Flow rate and volume. Station condition. Presence and assessment of trash.	D.1.d.(1)
		Field Monitoring	pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	D.1.d.(2)
		Analytical Monitoring	As outlined in **Appendix 5A**.	D.1.d.(3)
		Toxicity	Freshwater testing (salinity < 1 ppt): *Pimephales promelas* (Fathead Minnow), *Ceriodaphnia dubia* (Daphnid), *Selenastrum capricornutum* (Green Algae). Marine and Estuarine testing (salinity ≥ 1 ppt): *Strongylocentrotus purpuratus* (Purple Sea Urchin).	D.1.d.(4)
Dry Weather Receiving Water Monitoring Program (**Sections 5.3.1.1**, **5.3.1.2, and 5.3.1.3**)	Three per permit term according to sampling schedule[2]	Field Observations	Station identification and location, presence of flow, or pooled or ponded water, flow estimation and characteristics, pooled or ponded water characteristics (if applicable), and station description. Presence and assessment of trash.	D.1.c.(1)
		Field Monitoring	pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	D.1.c.(2)
		Analytical Monitoring	As outlined in **Appendix 5A**.	D.1.c.(3)
		Toxicity	Freshwater testing (salinity < 1 ppt): *Pimephales promelas* (Fathead Minnow), *Ceriodaphnia dubia* (Daphnid), and *Selenastrum capricornutum* (Green Algae). Marine and Estuarine testing (salinity ≥ 1 ppt): *Strongylocentrotus purpuratus* (Purple Sea Urchin).	D.1.c.(4)

SMR WMA MAP Component	# Events	Sample Type	Analyses	Permit Provision
	Once per Permit term according to sampling schedule	Bioassessment Monitoring	Macroinvertebrate samples, physical habitat characterization, freshwater algae, and Index of Biological Integrity (IBI) or California Stream Condition Index (CSCI) for benthic macroinvertebrates and algae.	D.1.c.(5)
		Hydromodification Monitoring	Channel conditions, location of discharge points, habitat integrity, photo documentation, channel erosion dimensions, causes of erosion/habitat impact.	D.1.c.(6)
Rainbow Creek Nutrient TMDL Monitoring (**Section 5.3.1.6**)	12 per year (monthly)	Field Observations	Presence of flow and flow rate estimation. Visual observations of odor, color, clarity, floatables, deposits, vegetation and biology.	Attachment E.3.d.(1)
		Field Monitoring	pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	Attachment E.3.d.(1)
		Analytical Monitoring	TDS, dissolved iron, sulfates, ammonia, nitrate, nitrite, organic nitrogen, TKN, total phosphorus, and dissolved ortho-phosphate.	Attachment E.3.d.(1)
Regional Monitoring Programs (**Section 5.3.1.4**)	Annually	SMC Regional Monitoring	Bioassessment monitoring, flow, conventional parameters, nutrients, flow regime, vertebrate occurrence, hydromodification screening and channel engineering checklist (at trend sites).	D.1.e.(1)(a)
Regional Monitoring Programs (**Section 5.3.1.4**)	Every five years	Bight Regional Monitoring	Sediment chemistry, toxicity, and benthic macroinvertebrate community sampling per SQO requirements.	D.1.e.(1)(b)

SMR WMA MAP Component	# Events	Sample Type	Analyses	Permit Provision
Sediment Quality Monitoring Program (**Section 5.3.1.5**)	One event every five years (follow-up sampling as needed)	Sediment Quality Monitoring (may be fulfilled by Bight Monitoring)	Sediment chemistry, toxicity, and benthic macroinvertebrate community sampling per SQO requirements and in accordance with Sediment Monitoring Plan and QAPP (Weston 2014).	D.1.e.(2)
Wet Weather MS4 Outfall Discharge Monitoring Program (**Section 5.3.2.1**)	Once per year at each Copermittee wet weather representative outfall monitoring station	Field Observations	Location, date, duration of storm event, rainfall estimate of storm event, duration between storm event sampled and the end of previous measurable (> 0.1 inch rainfall) storm event. Flow rate and volume.	D.2.c.(3)
		Field Monitoring	pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	D.2.c.(4)
		Analytical Monitoring	As outlined in **Appendix 5A**.	D.2.c.(5)
Dry Weather MS4 Outfall Discharge Monitoring Program (**Sections 5.3.2.2** and **5.3.2.3**)	Two per year at 80% of Copermittee major outfalls	Field Screening Monitoring	Station ID and location, flow (presence, estimation, characteristics, sources) pooled/ponded water (characteristics, sources), station condition, presence and assessment of trash, and evidence of illicit connection or illegal dumping.	D.2.b.(1)
	Two per year at each Copermittee highest priority persistent flow monitoring station	Field Observations	Location, date, duration of storm event, rainfall estimate of storm event, duration between storm event sampled and the end of previous measurable (> 0.1 inch rainfall) storm event. Flow rate and volume.	D.2.b.(2).(c)
		Field Monitoring	pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	D.2.b.(2).(d)
		Analytical Monitoring	As outlined in **Appendix 5A**.	D.2.b.(2).(e)

SMR WMA MAP Component	# Events	Sample Type	Analyses	Permit Provision
Rainbow Creek Progress to Goals Outfall Monitoring (**Section 5.3.2.4**)	At least four times per year	Field Observations	Presence of flow and flow rate estimation. Visual observations of odor, color, clarity, floatables, deposits, vegetation and biology.	Not required
WMA Special Study (**Section 5.3.3**)	On-going	SMRNIG Study	Algal bioassessment, dissolved oxygen, pH, temperature, conductivity, nutrients, water level, velocity, and discharge.	D.3.a.(1)
San Diego Region Special Study (**Section 5.3.3**)	On-going	SMC CLEAN (In-kind) Analytical and Field Monitoring	Nutrients, Indicator bacteria, metals, pH, temperature, specific conductivity, dissolved oxygen, and turbidity.	D.3.a.(2)

1. At least one wet weather monitoring event will be conducted during the first storm of wet season (October 1 – April 30) that meets mobilization criteria, and at least one wet weather monitoring event that occurs after February 1st.
2. At least one monitoring event will be conducted during the dry season (May 1 – September 30) and at least one monitoring event will be conducted during a dry weather period (i.e., antecedent dry period of at least 72 hours following a storm event producing measurable rainfall of greater than 0.1 inch) after the first measurable storm of the wet season (October 1 – April 30).

5.3.1 Receiving Water Monitoring

The Receiving Water Monitoring Program is designed to monitor the condition of the receiving waters in the SMR WMA during dry weather and wet weather conditions. Long-term receiving water monitoring will be conducted to assess the long-term trends and to evaluate attainment of numeric goals established in **Chapter 4**, as applicable and as further described in **Section 5.4.1**. The Permit requires receiving water monitoring at one long-term receiving water monitoring station from among the existing mass loading stations, temporary watershed assessment stations, bioassessment stations, and stream assessment stations previously established by the Copermittees to be representative of the receiving water quality in the SMR WMA; however, three long-term receiving water monitoring stations will be monitored within the WMA to ensure that differences in receiving water quality between the Upper, Middle, and Lower SMR Subwatersheds are adequately characterized. The three long-term receiving water monitoring stations will allow the Copermittees to assess the long-term trends and determine if conditions in receiving waters are improving.

In addition, the long-term receiving water monitoring stations will provide data that is representative of the overall health of the upstream waterbodies. For example, the median total nitrogen and total phosphorus results observed at the long-term receiving water monitoring station at the base of the Middle SMR Subwatershed are 0.70 mg/L and 0.12 mg/L, respectively. These median values fall within the range of the median values observed at the receiving water sites historically monitored within the Middle SMR Subwatershed.[18]

The District conducted reconnaissance to identify a new long-term receiving water monitoring station to be representative of the Upper SMR Subwatershed. The preferred site is located on Wilson Creek a few miles upstream of Vail Lake (**Figure 5-2**). The District will coordinate with the Rancho California Water District, County Transportation, or private property owner to establish long-term access to conduct monitoring at this location. As shown in **Figure 5-1**, Wilson Creek drains a substantial portion of the Upper SMR Subwatershed which includes a variety of land uses. Therefore, the new long-term receiving water station on Wilson Creek should be representative of the receiving water quality in Upper SMR Subwatershed. If long-term access cannot be established at the preferred station, then the new long-term receiving water station will be established at an alternative site on Wilson Creek, or on Temecula Creek as identified in **Figure 5-2**.

Monitoring is required during three wet weather events and three dry weather events per permit term. Both composite and grab sampling regimes will be used for sample collection during dry and wet weather events. Field observations and collection of field monitoring data will be conducted at the stations during all dry and wet weather events.

5.3.1.1 Receiving Water Wet Weather Monitoring and Dry Weather Monitoring

Three receiving water monitoring stations will be monitored. The locations are summarized in **Table 5-2** and mapped in **Figure 5-1** and **Figure 5-2**, respectively. The receiving water

[18] The ranges of median total nitrogen and total phosphorus results for all receiving water sites located within the Middle SMR subwatershed with a minimum sample size of four are 0.60 mg/L to 2.4 mg/L and 0.09 mg/L to 0.78 mg/L, respectively.

monitoring stations were determined by a selection process considering, but not limited to, representativeness, accessibility, safety, and hydrologic considerations.

Table 5-2. Long-Term Receiving Water Monitoring Station Locations

Station Name	Station ID	Latitude[1]	Longitude[1]
Upper Santa Margarita River, d/s confluence[2]	902USM828	33.4740	-117.1423
Wilson Creek[3]	902WLC650	33.4874	-116.9166
Lower Santa Margarita River, u/s Camp Pendleton[4]	SMR-MLS-2	33.3981	-117.2627

1. Latitudinal and longitudinal coordinates are approximate. Actual sampling location(s) may be adjusted accordingly based on monitoring and assessment criteria.
2. Station is representative of the receiving water quality from the Middle SMR.
3. Station is representative of the receiving water quality from the Upper SMR. This location on Wilson Creek has been selected as the new long-term receiving water station. In the event that long-term access cannot be established (e.g., access permissions or safety constraints) an alternative station on Wilson Creek at Sage Road (33°29'10.96"N/116°54'41.75"W), or at Upper Temecula Creek at Highway 79 (33°28'1.01"N/116°55'57.66"W) will be considered for selection as the long-term receiving water monitoring station representative of the Upper SMR Subwatershed.
4. Station is representative of the receiving water quality from the Lower SMR.

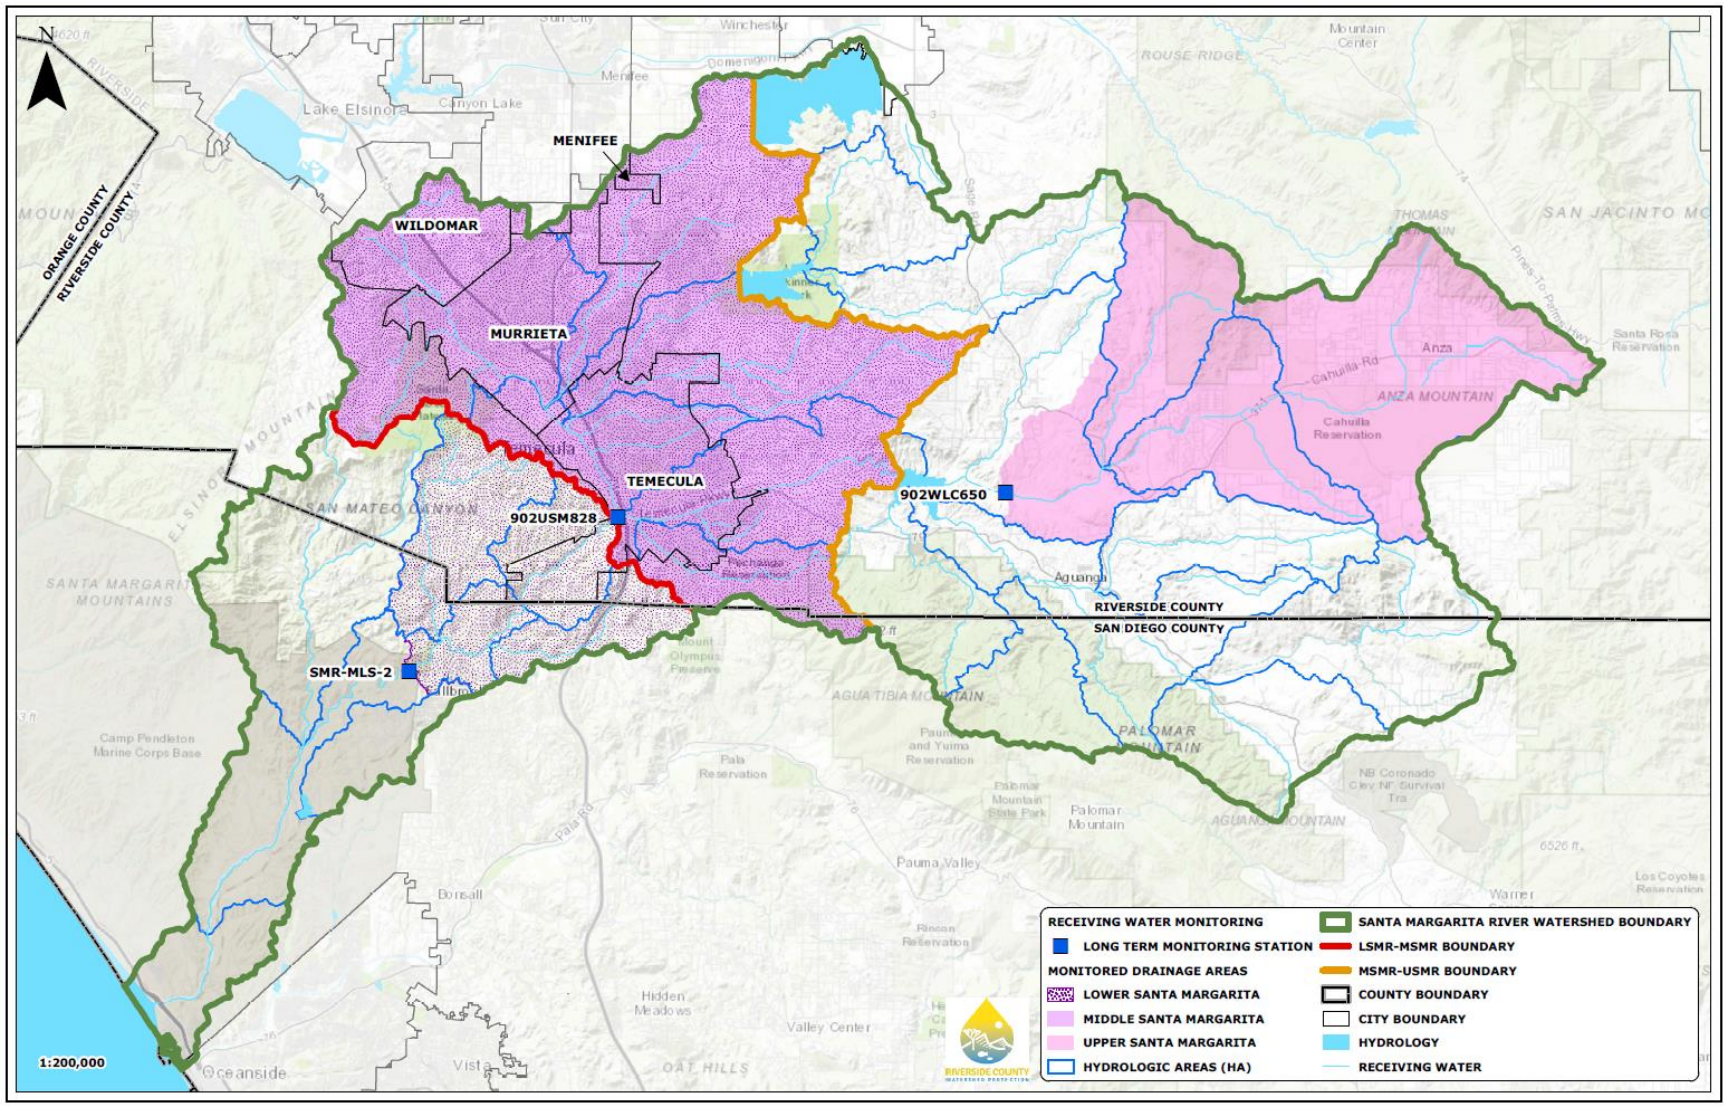

Figure 5-1. Long-Term Receiving Water Monitoring Station Locations for Upper, Middle, and Lower SMR Subwatersheds

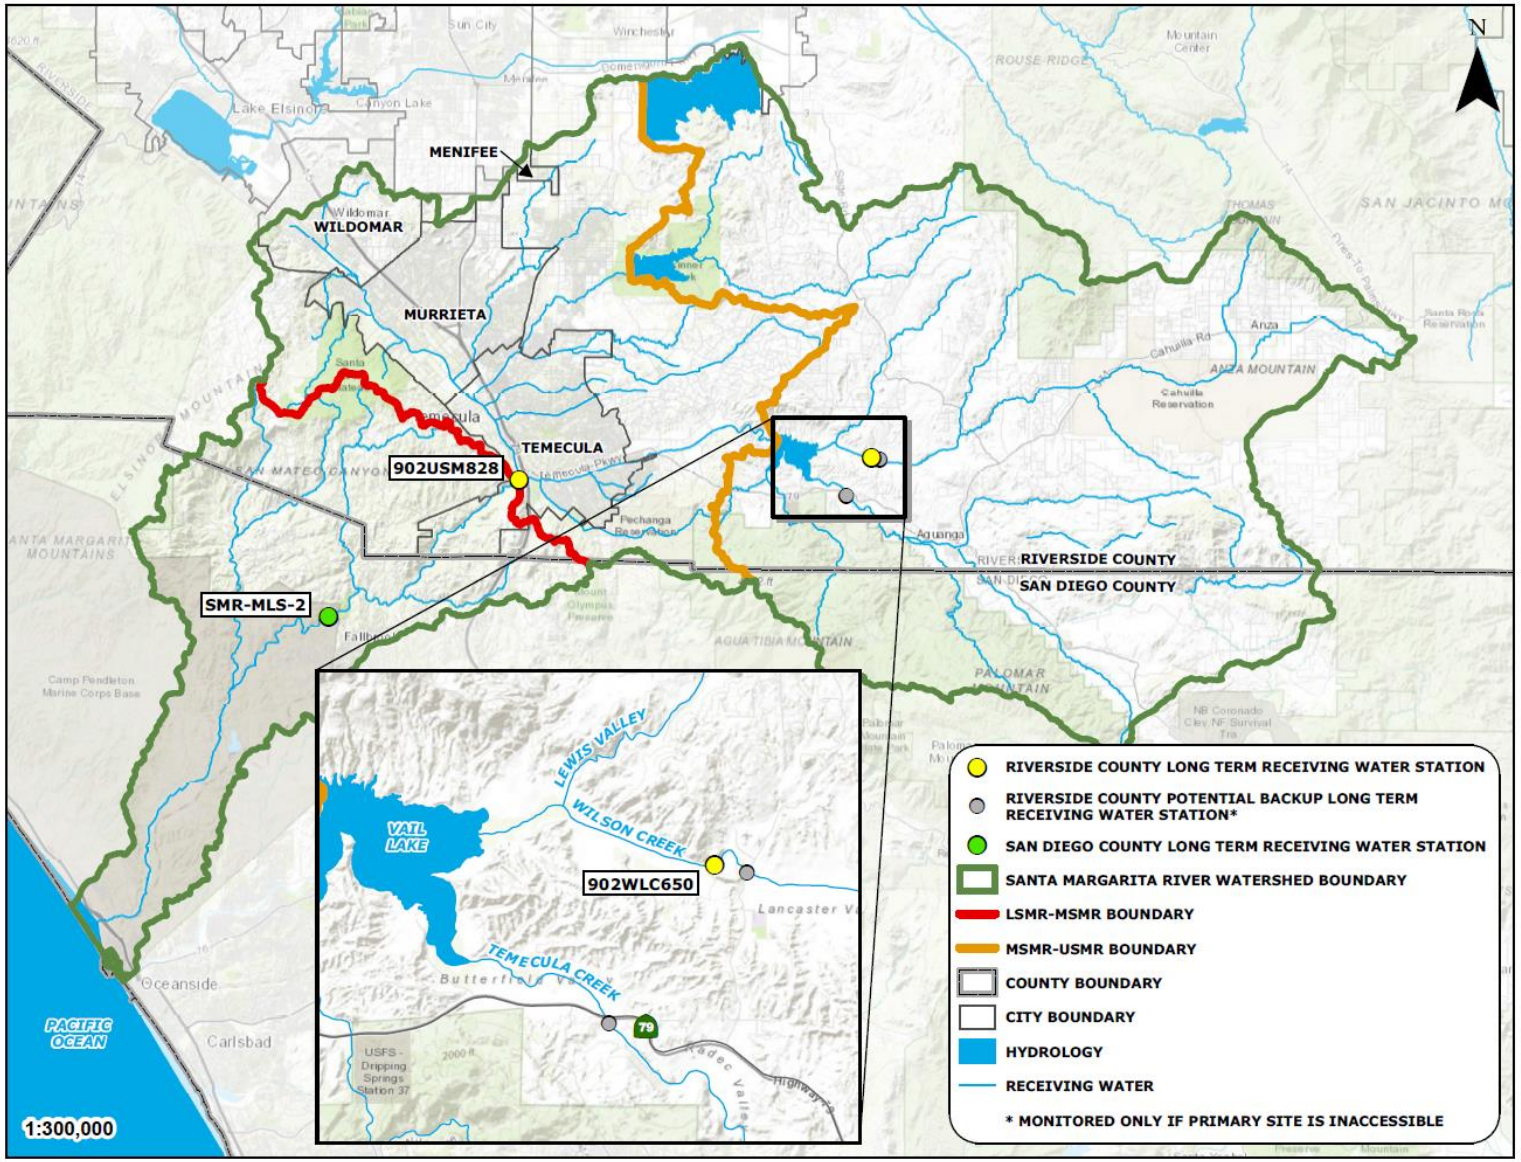

Figure 5-2. New Long-Term Receiving Water Site and Potential Back-up Sites for Upper SMR Subwatershed

Bioassessment monitoring and hydromodification monitoring will be conducted at the receiving water stations during at least one dry weather monitoring event during the permit term. Sediment quality monitoring will also be conducted in the SMR Estuary. Details regarding the analysis for each type of monitoring are provided in **Appendix 5A**. **Table 5-3** outlines a tentative schedule for performing each element of the receiving water monitoring program. Monitoring events are tentatively scheduled to support required assessments per Permit Provision D.4.

Table 5-3. Tentative Receiving Water Monitoring Program Schedule[1]

Receiving Water Monitoring Program Element	Reporting Year (# of Events)[2]				
	18/19	19/20	20/21	21/22	22/23
Wet Weather Monitoring					
Upper SMR Subwatershed		3[3]			
Middle SMR Subwatershed		3[3]			
Lower SMR Subwatershed		3[3]			
Dry Weather Monitoring					
Upper SMR Subwatershed			3[4]		
Middle SMR Subwatershed			3[4]		
Lower SMR Subwatershed		3[4]			
Bioassessment Monitoring					
Upper SMR Subwatershed			1		
Middle SMR Subwatershed			1		
Lower SMR Subwatershed		1			
Hydromodification Monitoring					
Upper Subwatershed			1		
Middle SMR Subwatershed			1		
Lower SMR Subwatershed		1			

1. While the total number of events identified for each receiving water monitoring program element will not change, the reporting years during which monitoring is conducted may change if deemed necessary by the Copermittees.
2. The reporting year for the Monitoring and Assessment Program extends from October 1st to September 30th of the following year.
3. At least one wet weather monitoring event will be conducted during the first storm of the wet season (October 1 – April 30) that meets mobilization criteria, and at least one wet weather monitoring event will be conducted after February 1st. The reporting year during which these events take place will be determined based on rainfall intensity and resource availability.
4. At least one monitoring event will be conducted during the dry season (May 1 – September 30) and at least one monitoring event will be conducted during a dry weather period (i.e., antecedent dry period of at least 72 hours following a storm event producing measurable rainfall of greater than 0.1 inch) after the first measurable storm of the wet season (October 1 – April 30). The reporting year during which these events take place will be determined based on resource availability.

5.3.1.2 Receiving Water Bioassessment Monitoring

The Permit requires bioassessment monitoring for each LTMS for one dry weather event per permit term. Bioassessment monitoring at the receiving water monitoring stations will be conducted simultaneously with a receiving water monitoring station dry weather monitoring event. The bioassessment monitoring will be comprised of collecting macroinvertebrate samples, physical habitat characterization measurements, and freshwater algae samples. Bioassessment monitoring is designed to be SWAMP compatible and samples are used to calculate an Index of biotic integrity (IBI) and/or California Stream Condition Index (CSCI) for macroinvertebrates and algae. Bioassessment monitoring may be conducted in accordance with the "Triad" assessment

approach that includes the collection of water chemistry and toxicity data as well (Stormwater Monitoring Coalition, 2004). Detailed proposed monitoring methods and procedures are presented in **Appendix 5A**.

5.3.1.3 Hydromodification Monitoring

The Permit requires hydromodification monitoring to be conducted as part of the Copermittees' approved Hydromodification Management Plans[19] in **Appendix 5B** (Section III; Appendix K) and **Appendix 5C** (Section 8) as well as hydromodification monitoring at each receiving water monitoring station for one dry weather event per permit term.

Hydromodification monitoring was initiated as specified in the April 2016 revision to Appendix K of the Riverside County SMR Hydromodification Management Plan (HMP Monitoring). HMP Monitoring will be conducted annually at two stations, Warm Springs Creek and Meadowview Stream (**Table 5-4** and **Figure 5-2**) through spring of 2019[20]. Hydromodification monitoring as specified in the 2011 Regional HMP for the County of San Diego did not include any monitoring sites in the SMR WMA.

Dry Weather Receiving Water Hydromodification Monitoring in the Middle SMR Subwatershed will occur in conjunction with receiving water dry weather monitoring, and may be conducted in coordination with special studies and regional monitoring programs, such as the SMC Regional Monitoring Program, when feasible. The monitoring conducted in the Lower SMR subwatershed will coincide with the spring receiving water dry weather monitoring event in May or June and the dry weather receiving water bioassessment monitoring.

Table 5-4. Hydromodification Monitoring Sites (HMP Monitoring)

	Station Name	Station ID	Latitude	Longitude
HMP Monitoring	Warm Springs Creek	901HDM001	33˚32'54.02" N	117˚10'14.24" W
	Meadowview Stream	902HDM002	33˚31'22.66" N	117˚07'51.46" W
Long Term Receiving Water Hydromodification Monitoring	See Table 5-2			

Observations and measurements will be collected in accordance with each County specific HMP. Detailed proposed monitoring methods and procedures are presented in **Appendix 5A Section 2.7**.

[19] Refers to Hydromodification Management Plans as approved under the prior Permit for Riverside County Co-Permittees within the Santa Margarita Watershed (Order No. R9-2010-0016) and under the prior Permit for the County of San Diego within the Santa Margarita Watershed (Order No. R9-2007-0001).

[20] All analytical data and a final report, as described in the April 2016 revision to Appendix K of the Riverside County SMR HMP, will be submitted to the San Diego Water Board by October 31, 2019.

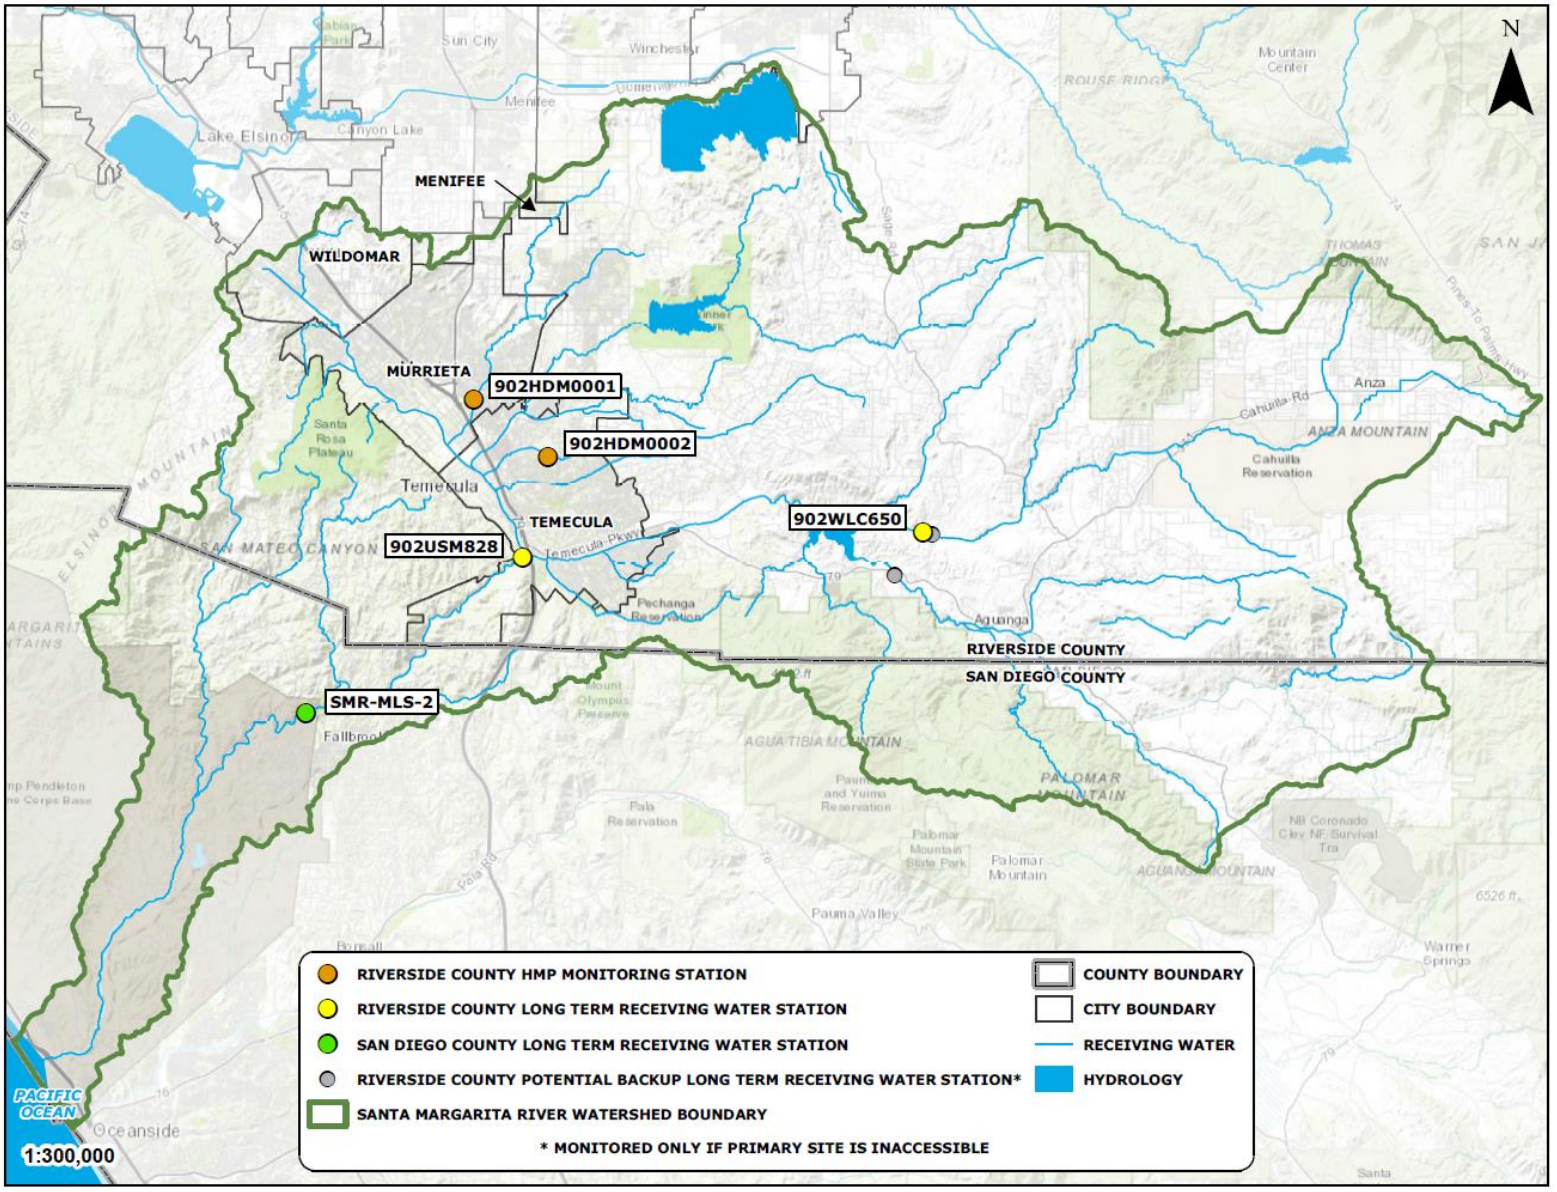

Figure 5-3. Hydromodification Monitoring Station Locations

5.3.1.4 Regional Monitoring Programs

Regional Monitoring Programs have been developed with the purpose of increasing the effectiveness of existing NPDES monitoring programs by integrating the efforts of Copermittees to achieve a large-scale assessment of the watershed condition. Certain monitoring efforts have been incorporated into these regional programs for the purpose of establishing a holistic and coordinated approach, the details of which are available in the applicable regional monitoring plans. Copermittees will participate in these regional programs to meet the requirements of Permit Provision D.1.e (1). These programs are summarized below.

5.3.1.4.1 Southern California Stormwater Monitoring Coalition

Since 2001, the Copermittees have partnered with regulated stormwater municipalities in Southern California, the RWQCBs of Southern California and the Southern California Coastal Water Research Project (SCCWRP) to form the SMC. The Copermittees are continuing to participate in the SMC Regional Freshwater Stream Bioassessment Monitoring Program. In 2015, a new five-year SMC program began that extended the initial survey to answer key management questions about the impacts of stormwater on stream conditions. Several modifications were made to the previous surveys to emphasize detection of trends and to address data gaps. Specifically, monitoring of high-priority stressors (i.e., habitat, nutrients, and ionic composition) was continued, whereas monitoring of low-priority stressors (i.e., water column metals, pyrethroids, and toxicity) was discontinued. Flow regime (hydrologic state checklist derived from Gallart et al. [2010] and water level loggers), vertebrate occurrence, and new stressors of interest (i.e., sediment pyrethroids and toxicity) were added to the list of monitored parameters. Sediment sampling was deferred by the SMC Executive Committee until the 2017 monitoring year.

In addition, the physical habitat assessment has been enhanced with hydromodification screening (modified from Bledsoe et al., 2010) at unarmored or partially armored "condition" sites (i.e., sites selected in a probabilistic way to represent the typical condition of streams in the region) and a channel engineering checklist at all condition sites. The hydromodification screening and channel engineering checklist will be conducted at "trend" sites (i.e., sites that are revisited) at least once during the five-year study. The trend sites were selected from previously sampled sites under earlier probabilistic surveys in order to estimate changes in regional conditions over time, and the condition sites were selected from a new probabilistic sample draw in order to estimate current regional conditions.

5.3.1.4.2 Southern California Bight Regional Monitoring

Provision D.1.e.(1)(b) of the Permit also requires the Copermittees to participate in the Bight Regional Monitoring Program, an integrated assessment of the Southern California Bight, that occurs every five years and consists of a partnership of multiple local, state, and federal agencies overseen by SCCWRP. The Bight Regional Monitoring Program assesses the ecological health of nearshore and offshore marine habitats as well as coastal embayments by measuring indicators of environmental condition (e.g., habitat quality, sediment contamination, toxicity, infaunal communities, and fish communities). Participation in the Bight Regional Monitoring Program may be used to fulfill the sediment quality monitoring requirements of Permit Provision D.1.e.(2).

5.3.1.5 Sediment Quality Monitoring

The Copermittees are required either individually, in association with multiple Copermittees, or through participation in a waterbody monitoring coalition to perform sediment quality monitoring to assess compliance with the sediment quality receiving water limits applicable to MS4 discharges to enclosed bays and estuaries. Provision D.1.e.(2) of the Permit requires the Copermittees to conduct sediment monitoring which satisfies the requirements of the *Water Quality Control Plan for Enclosed Bays and Estuaries of California – Part I Sediment Quality* (Sediment Control Plan) (State Water Board and California Environmental Protection Agency [CA EPA], 2009). Data are assessed using sediment quality objectives (SQOs) which are based on a multiple lines of evidence (MLOE) approach. The lines of evidence (LOE) are sediment toxicity, sediment chemistry, and benthic community condition. The MLOE results are integrated through the evaluation of the severity of biological effects and the potential for chemically-mediated effects to provide a final site level assessment. The integration of all three measurements help to provide a comprehensive assessment of the sediment condition of lagoons in San Diego County using the most up-to-date protocols.

5.3.1.6 TMDL Monitoring

The SMR WMA has one existing TMDL, established in 2006, which is the *Total Maximum Daily Loads for Total Nitrogen and Total Phosphorus in Rainbow Creek Watershed* (Nutrient TMDL). The goal of the Nutrient TMDL is to achieve the pollutant load reductions necessary to restore and protect the designated aquatic life beneficial uses in the Rainbow Creek sub-watershed. The monitoring program provides data on baseline conditions and trends for nutrients in the Rainbow Creek Subwatershed. The resulting data may be used in evaluating BMP effectiveness to reduce nutrient loading to the creek, and tracking changes in water quality and the trajectory to attain the TMDL goals in Rainbow Creek and its tributaries over time. Monitoring in compliance with the Nutrient TMDL addresses the following questions:

- How do the mean concentrations of total nitrogen and total phosphorous vary among the sampling sites in the Rainbow Creek mainstem and tributaries?
- Are there any significant trends in total nitrogen and total phosphorus concentrations in the Rainbow Creek main stem and tributaries over time?

In situ monitoring for field parameters and grab sampling for nutrients, TDS, iron and sulfate are conducted at 14 locations in the Rainbow Creek Subwatershed. Monitoring events are conducted during dry weather (i.e., not within 72 hours of a rain event totaling 0.1 inch or greater) at approximately 30-day intervals from October to September of each monitoring year. The flow rate at each site is estimated using channel cross-section dimensions and either a hand-held flow meter or the floating object technique to measure current velocity.

Monitoring methods are further described in **Appendix 5A**. Compliance with the Nutrient TMDL is evaluated by comparing monitoring results with final receiving water limitations (i.e., 1 mg/L for total nitrogen, 0.1 mg/L for total phosphorus, and 10 mg/L for nitrate as N).

Table 5-5. Rainbow Creek Nutrient TMDL Monitoring Station Locations

Station ID	Site Description	Latitude	Longitude
	Main Stem		
RBC01	Rainbow Creek @ Eastern edge of Hines Nursery	33.42042	-117.13571
RBC02	Rainbow Creek @ Huffstatler Road	33.41544	-117.15199
RBC04	Rainbow Creek @ Old Highway 395	33.41272	-117.15853
RBC06[1]	Rainbow Creek @ 2219 Willow Glen Road	33.40881	-117.20539
RBC10	Rainbow Creek @ MWD Crossing	33.40696	-117.18344
SMG05	Rainbow Creek @ Willow Glen Road	33.40788	-117.20104
SMG06	Rainbow Creek @ Stage Coach Lane	33.41056	-117.21477

5.3.2 MS4 Outfall Monitoring

The MS4 Outfall Monitoring Program is designed to assess the effectiveness of Copermittees JRMPs and WQIP strategies at prohibiting non-storm water discharges into the MS4 and reducing pollutants in stormwater discharges from their MS4s to the maximum extent practicable (MEP). MS4 outfall monitoring may also be used to evaluate attainment of numeric goals established in **Chapter 4**, as applicable and as further described in **Section 5.4.1**. The MS4 Outfall Program consists of wet weather sampling of discharges from the representative major outfalls, as well as field screening monitoring and non-storm water persistent flow MS4 outfall discharge monitoring during dry weather. In addition, the County of San Diego conducts further MS4 outfall monitoring associated with the HPWQC in the Rainbow Creek Subwatershed in a voluntary monitoring program that provides data to assess progress to goals.

5.3.2.1 MS4 Outfall Wet Weather Monitoring

Each Copermittee with MS4 outfalls within the WMA has identified one major outfall station within their jurisdiction for wet weather MS4 outfall discharge monitoring as shown in **Table 5-6** and **Figure 5-5**. These six representative major outfall stations (or alternative stations identified during adaptive management) will be monitored in the SMR WMA to meet Permit requirements.

Table 5-6. MS4 Outfall Wet Weather Monitoring Station Locations

Station Number	Receiving Water	Permittee[1] Assigned	Site Description	Latitude	Longitude
902MS41 033	Tucalota Creek	RCFCWCD	Outlet to W side of Tucalota Creek south of M.H.S. Rd.	33.5521	-117.1364

HST01	Rainbow Creek	County of San Diego	Brow Ditch to Rainbow Creek @ Huffstatler Street	33.4151	-117.1520

1. The City of Menifee does not have a MS4 outfall.

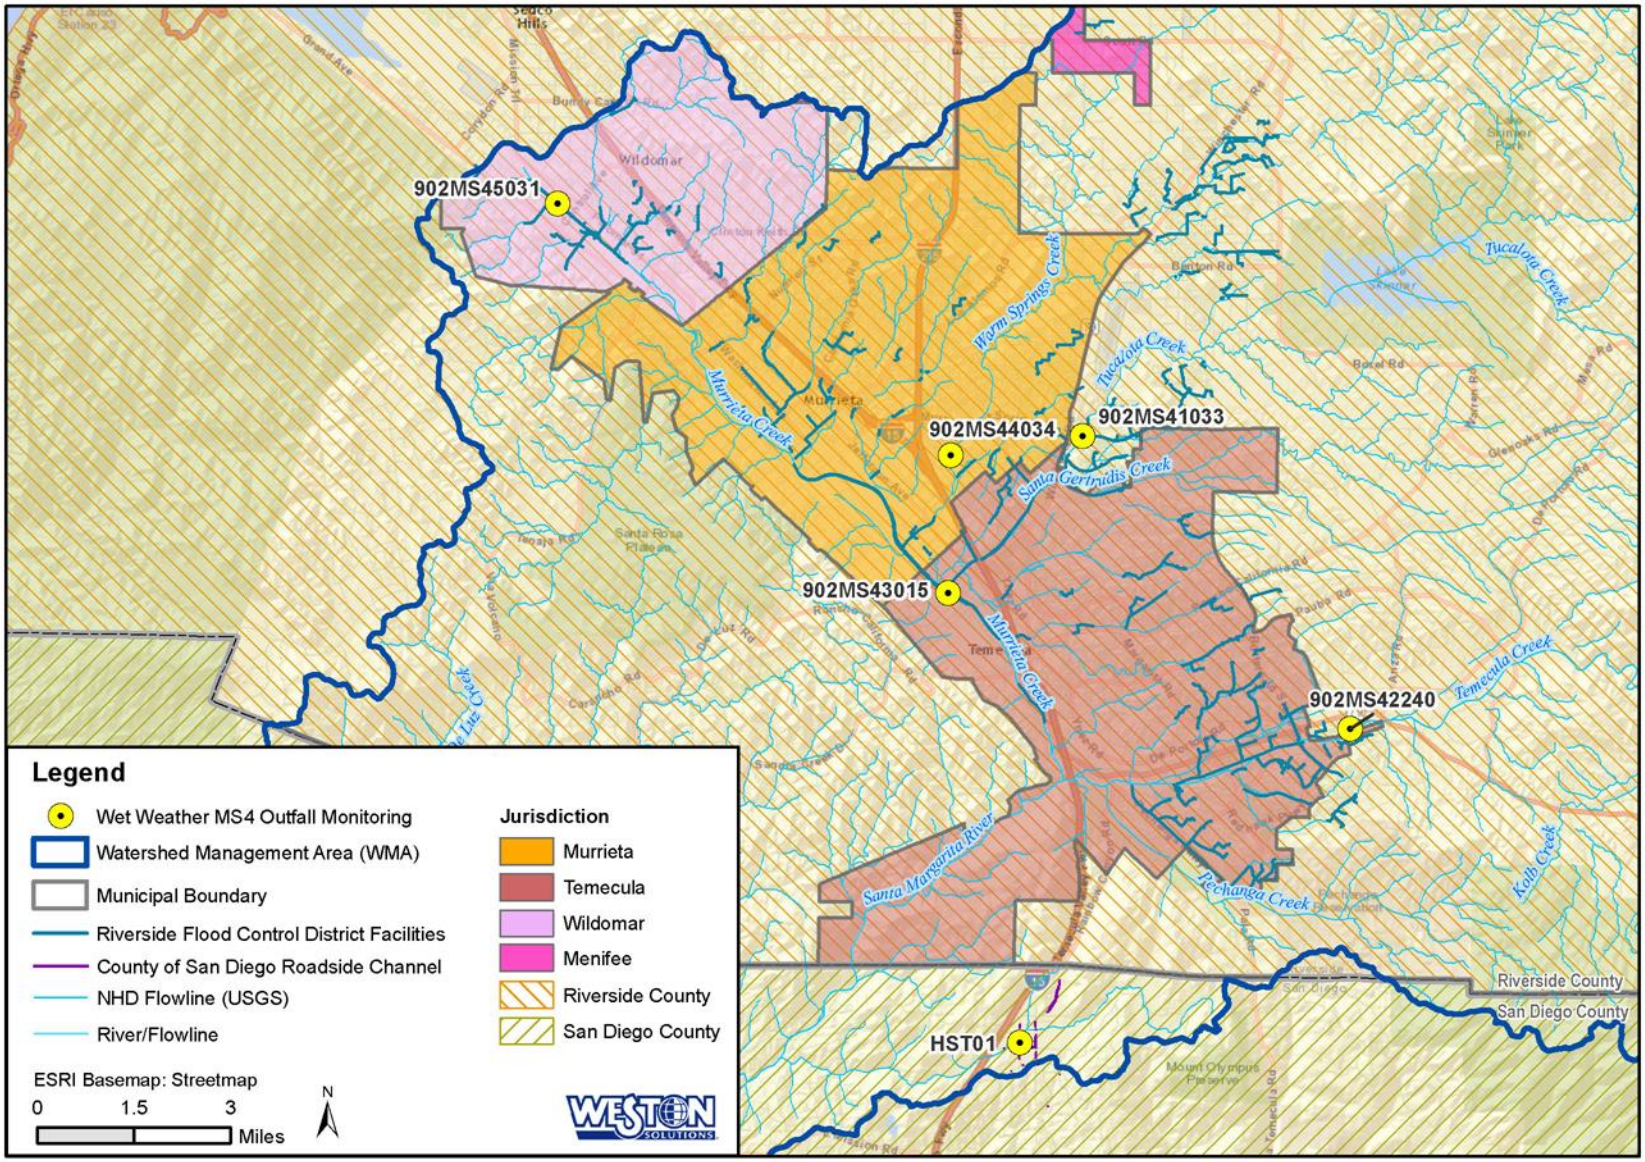

Figure 5-5. MS4 Outfall Wet Weather Monitoring Station Locations

The six representative major outfalls will be monitored once per year during wet weather events. The outfalls will continue to be monitored unless new information becomes available which warrants consideration of new stations. If new information becomes available which warrants consideration of new stations, the Copermittees will re-evaluate the stations and potentially recommend new stations via the adaptive management process. Modifications to monitoring locations will be reported in the WQIP Annual Report. Detailed proposed monitoring methods and procedures are presented in **Appendix 5A**.

5.3.2.2 Dry Weather MS4 Outfall Discharge Field Screening Monitoring

Dry weather MS4 outfall discharge field screening monitoring consists of collecting visual observations at Copermittee major outfalls. The Permit identifies the required frequency for dry weather MS4 outfall discharge field screening monitoring based on the number of major outfalls within a Copermittee's jurisdiction. As shown in **Table 5-7**, each Copermittee has less than 125 major MS4 outfalls within the SMR WMA. The initial requirement for each Copermittee is to visually inspect at least 80 percent of the outfalls twice per year during dry weather conditions. The Permit also allows the Copermittees to adjust the field screening monitoring frequencies and locations for the MS4 outfalls in its inventory, as needed, to identify and eliminate sources of persistent flow non-storm water discharges in accordance with the HPWQC identified in the WQIP, provided the number of visual inspections performed is equivalent to the number of visual inspections initially required. The Copermittees will, at a minimum, conduct the total number of visual inspections identified within **Table 5-7** each year and the frequencies and locations for the MS4 outfalls which are inspected may be adjusted in accordance with the flexibility allowed in the Permit, as needed. Detailed proposed monitoring methods and procedures are presented in **Appendix 5A**.

Table 5-7. Dry Weather MS4 Outfall Discharge Field Screening Monitoring Frequency

Copermittee	Total Number of Major Outfalls in SMR WMA	80% of Major Outfalls	Number of Visual Inspections Required Per Year
RCFCWCD	84	68	136
County of Riverside	7	6	12
Menifee	0	0	0
Murrieta	31	25	50
Temecula	119	96	192
Wildomar	11	9	18
County of San Diego	11	9	18

5.3.2.3 Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring

Based upon the dry weather MS4 outfall discharge field screening monitoring records available upon the submittal of the WQIP and other pertinent factors (e.g., safety conditions, site accessibility, flow vs. ponded observations, tributary influences), each Copermittee identified and prioritized the MS4 outfalls observed to have persistent flow. This information was then used by the Copermittees to prioritize the MS4 outfalls based on their potential to contribute to the

HPWQC identified in **Chapter 2**. Target areas within the SMR WMA were identified using several factors (detailed in **Chapter 4**) which are expected to significantly correlate with the nutrient loading being discharged through the MS4. Persistently flowing outfalls are shown in **Figure 5-6**. Copermittees prioritized persistently flowing outfalls; however, where less than five persistently flowing outfalls were identified, the next highest priority transient outfall was selected. **Figure 5-7** illustrates the thirty preliminary highest priority MS4 outfall discharge monitoring stations that will be monitored in the SMR WMA during implementation of the SMR WQIP. Each Copermittee has selected five MS4 outfall discharge monitoring stations within the WMA, except for the City of Menifee, which does not have a MS4 outfall.

902MS45026	Wildomar	33.5971	-117.2228
MS4-SMG-015	County of San Diego	33.3748	-117.2526
MS4-SMG-021	County of San Diego	33.3748	-117.2526
MS4-SMG-057	County of San Diego	33.4203	-117.1532
MS4-SMG-024	County of San Diego	33.3720	-117.2560
HST01	County of San Diego	33.4151	-117.1520

Each of the highest priority non-storm water persistent flow MS4 outfall monitoring stations identified in **Table 5-8** and **Figure 5-7** will be monitored under dry weather conditions at least semi-annually until one of the following criteria occur:

- The non-storm water discharges have been effectively eliminated (i.e. no flowing, pooled, or ponded water) for three consecutive dry weather monitoring events, OR
- The source(s) of the persistent flows has been identified as a category of non-storm water discharges that does not require a NPDES permit and does not have to be addressed as an illicit discharge because it was not identified as a source of pollutants (i.e. constituents in non-storm water discharge do not exceed Non-Storm Water Action Levels [NALs] identified in Permit Provision C.1 [inclusive of any future iterations]), and the persistent flow can be re-prioritized to a lower priority, OR
- The constituents in the persistent flow non-storm water discharge do not exceed NALs, and the persistent flow can be re-prioritized to a lower priority, OR
- The source(s) of the persistent flows has been identified as a non-storm water discharge authorized by a separate NPDES permit.

If one of the criteria for discontinuing monitoring is met, or the threat to water quality has been reduced (per Permit Provision D.2.b.(2)(b)(iii)), a Copermittee can replace the persistent flow MS4 outfall monitoring station with their next highest prioritized outfall within the WMA, unless there are no remaining qualifying major MS4 outfalls within their jurisdiction within the WMA. Copermittees are not required to sample ponded water, as the requirements of Permit Provision D.2.b.(2)(e) specify collection during monitoring events "in which measurable flow is present…". Ponded or pooled water may have conditions not found in flowing water and may not reach receiving waters. Sites visited during semi-annual monitoring events that do not have measurable flow may result in an analytical data gap. Therefore, Copermittees may elect to replace highest priority outfalls that become transient, and a reduced threat to water quality can be demonstrated, with persistently flowing outfalls. **Table 5-8** and **Figure 5-7** will be updated accordingly as stations are rotated and any updates will be presented in the WQIP Annual Report. Detailed proposed monitoring methods and procedures are presented in **Appendix 5A**.

5.3.2.4 Rainbow Creek Progress Towards Goals Outfall Monitoring

The County of San Diego will continue to conduct monitoring in the Rainbow Creek Subwatershed to assess the contribution of urban runoff to Rainbow Creek. This non-storm water monitoring effort currently includes at least quarterly visits to 21 outfalls in this subwatershed during dry weather (i.e., no daily precipitation greater than 0.1 inches within 72 hours prior to the visit). A hand-held flow meter or the floating object technique is used to measure current velocity. **Appendix 5A** provides additional details regarding this monitoring effort including monitoring locations.

5.3.3 Special Studies

Special Studies as required under the Regional Permit are intended to address data gaps and/or to facilitate the development of information necessary to more effectively address the pollutants and/or stressors as relevant to the HPWQC in the WMA, as well as impacts to the receiving waters in the region. A description of these special studies are included in Sections 5.3.3.1 and 5.3.3.2. The Copermittees also participate in additional special studies for the benefit of their local and regional program efforts. A description of other special efforts are included in Section 5.3.3.3. Special Studies have their own separate stand-along workplans. Updates to Special Studies'

Workplans and progress of Special Studies efforts will be included in the Annual Monitoring and Assessment reports.

5.3.3.1.1 WMA Special Study - SMRNIG Study

The SMRNIG, formed in 2011, is a collaboration of stakeholders from within the watershed for the purpose of monitoring and assessing water quality in order to evaluate and address impairments due to biostimulatory substances in the estuary and river. The SMR Stakeholder Group is funded largely through the Integrated Regional Water Management (IRWM) process and is currently receiving a Proposition 84 grant from the State of California with matching funding and in-kind services provided by the County of San Diego, District, Southern California Coastal Water Research Project (SCCWRP), United States Marine Corps (USMC) Base Camp Pendleton, and the Regional Board. A Technical Advisory Committee led by SCCWRP coordinates the technical studies at the bequest of the SMR Stakeholder Group.

Current nitrogen and phosphorus water quality objectives are problematic, in part, because they do not consider site-specific factors. The Nutrient Numeric Endpoint (NNE) framework, an alternative regulatory approach advocated by SWRCB staff and United States Environmental Protection Agency (USEPA) Region 9, is currently in development. As a result, the methods for protecting beneficial uses from biostimulatory substances are aimed at addressing the cause of potential impairments rather than focusing on controlling nutrient concentrations in of themselves. This framework can be used to develop scientifically-sound nutrient water quality goals for the Estuary and river that are protective of their beneficial uses.

In support of the development of the NNE framework the Copermittees targeted sites for in-kind sampling to provide the study with additional nutrient data, selected in coordination with SCCRWP. Samples collected included analysis of ammonium, orthophosphate, TDN, TDP, particulate organic carbon, particulate organic nitrogen, particulate phosphorus, phytoplankton chlorophyll a, algal CN content, and algal phosphorus content. During WQIP implementation Copermittees will continue to support the study effort by including in-kind monitoring of additional NNE relevant parameters at the long-term receiving water station during a dry weather monitoring event. The Copermittees will continue to support future phases of the NNE development efforts.

Currently, the Regional Water Board is preparing a draft resolution and staff report that will support water quality goals for the Estuary that was developed with the consideration of stakeholder input. The resolution is scheduled to be released for public comment in spring 2018 and is based on technical studies supported by the SMR Stakeholder Group (Sutula et al., 2016). The next stage of the project will develop proposed water quality goals for the Santa Margarita River downstream of the confluence with De Luz Creek. By May 2018, the Technical Advisory Committee will develop a preliminary report that evaluated potential goals for this section of the river that is based on scientific studies and model simulations. Additional discussions of the SMR stakeholder Group will ensue that use the results of this preliminary technical report to inform the Stakeholder Group in developing recommended goals for this section of the river for the Regional Water Board's consideration. Final goals developed for the River will be considered as part of the integrated assessment of the WQIP.

5.3.3.1.2 San Diego Region Special Study - SMC CLEAN Project

The SMC California LID Evaluation and Analysis Network (SMC CLEAN) will develop a thorough understanding of the effectiveness of LID BMPs in California: in the short term for use in calibration of performance expectations for watershed programs; and in the long term for modification of LID design, construction, and maintenance. This can only be accomplished with the help of project partners and others performing LID monitoring. The District, on behalf of the Copermittees is a cost-sharing project partner and provides in-kind services for this special study. In-kind monitoring services are accomplished by sharing the data resulting from the District's 15-acre LID Integrated Management Plan Testing and Demonstration Facility. The facility is being used to monitor the performance of LID features in the field, illustrate LID features in training workshops, and assist in the development of technical guidance regarding LID features. Flow data and influent and effluent samples are collected in accordance with the District's LID Monitoring Plan and QAPP (Appendix 5G). The District is collaborating with the SMC CLEAN's overarching LID BMP evaluation project. The results of this monitoring study will be used to establish water quality treatment effectiveness and numeric criteria for crediting flow reductions to developments that implement these BMPs. The SMC CLEAN project will be used to:

- Develop specific LID research questions;
- Research existing LID monitoring data;
- Develop a standard methodology for monitoring LID BMPs including coordination with other SMC projects concerned with monitoring methodology;
- Coordinate ongoing LID monitoring;
- Implement LID monitoring through the standard methodology and monitoring protocol developed;
- Compile and analyze LID monitoring data;
- Develop recommendations; and
- Conduct a review and update of the Southern California LID Manual.[21]

The updated LID Manual will provide enhanced guidance for design, construction, and maintenance of various LID BMPs to improve their performance in removing pollutants and reducing hydrologic changes. This is a regional project with many participating agencies including UCSD, Riverside County Flood Control and Water Conservation District, Orange County Public Works, the Council for Watershed Health, Loyola Marymount University and the US South Coast Research and Extension Center. As the project progresses, improvements in technology and understanding of BMPs effectiveness in treating a variety of stormwater pollutants (including nutrient) will be assessed and implemented. This regional effort will provide information filling the data gap on the effectiveness of LID BMPs and to and provide guidance on the performance expectations for watershed programs. Assessment based on findings of this special study will be dependent on the schedule for the updated LID Manual.

5.3.3.1.3 Additional Special Studies or Related Monitoring Efforts

San Diego Regional Reference Streams Study

[21] https://www.casqa.org/sites/default/files/downloads/socallid-manual-final-040910.pdf

The San Diego Regional Reference Stream Study serves as the regional special study for the Santa Margarita WMA. The study was conceived by the San Diego, Orange County and Riverside Permittees, funded by San Diego and Orange County, and fulfills the regional special study requirement in Permit Provision D.3.(a). The goal of this project was to collect the data necessary to derive reasonable and accurate numeric targets for bacteria, nutrients, and heavy metals by referencing natural, local conditions. The study develops levels that account for natural sources to establish the concentrations or loads from streams in a minimally disturbed or reference condition. The study considers the size, geology and wet or dry conditions of the catchment. This study provides a scientific basis for evaluating compliance levels in TMDLs. The results of this study were used to support the forthcoming reopener of the regionally adopted Bacteria TMDLs and to support numeric targets in future TMDLs for bacteria, nutrients, and metals. For additional details see SCCWRP Technical Report 862: Wet and Dry Weather Natural Background Concentrations of Fecal Indicator Bacteria in San Diego, Orange, and Ventura County, California Streams (Tiefenthaler et al., 2015) (http://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/862_StreamFIBs.pdf). The draft report on the measured concentrations of nutrients and metals in streams in minimally disturbed watersheds will be released in the near future for review and comment.

Laboratory Intercalibration

Beginning in 2003, and continuing in 2006 and 2009, the SMC implemented a series of intercalibration studies to promote comparability of water chemistry measurements. The 2003 intercalibration study established common reporting levels and target analytes, and utilized iterative round robin exercises to minimize interlaboratory variation. During this permit term the SMC commissioned an intercalibration study to quantify stormwater-sample testing comparability among laboratories for toxicity methods. This study aimed at assessing variability among laboratories, identifying potential quality improvements, and improving comparability and consistency in toxicity measurements. This regional Intercalibration effort is expected to be useful in addressing data gaps necessary to more effectively address the stressors that are impacting receiving waters on a regional basis in the San Diego, and specifically toxicity is one of the priority water quality conditions of concern in this WMA. The successes and benefits derived from the chemistry laboratory intercalibration, the toxicity testing intercalibration study provides an important first step towards improving toxicity testing data quality and comparability on a regional basis.

A round robin exercise was conducted to characterize and ultimately minimize inter-laboratory variability for testing marine and freshwater species, and developed a manual to provide guidelines for testing precision and sensitivity. The SMC has conducted similar studies with its chemical testing program to address comparability issues. These studies have provided a platform to quantify the range of variability and a vehicle to improve the variability among testing laboratories.

A Laboratory Working Group composed of expert laboratory managers from the participating institutions selected the toxicity methods, species, and endpoints for the round robin exercise. In addition, the group is developing pass/fail comparability evaluation criteria for data generated by participating laboratories. Iterative sample testing with freshwater and marine species was conducted. The species and endpoints selected for testing freshwater samples were the 7-day chronic survival and reproduction test for *Ceriodaphnia* and the 96-hour acute survival test for *Hyalella*. For marine or estuarine receiving environments, the species and endpoints selected are the larval development test with purple sea urchin (72 hours) and larval mussel survival and

development (48 hours). These species were selected by the group because they are the most commonly tested permit organisms; they also are sensitive, easy to conduct the test with, readily available, representative of local species, and have relatively high variability of test method.

This SMC intercalibration study identified poor comparability in *Ceriodaphnia dubia* reproduction results among laboratories, as well as between samples within individual laboratories. This variability raised concerns regarding the ramifications of assessment errors in toxicity test results which can include incorrect status of waterbodies on the Clean Water Act 303(d) listing or the initiation of unnecessary toxicity reduction evaluations. This data was then used to assess real world scenarios of listed waterbodies. Even when assuming the low end of the variability scenarios, more than 50% of the test results could be overturned in either direction. The final recommendations of this study are to either discontinue use of *C. dubia* to be replaced by an alternate species approved by the EPA, or to consider conducting additional interlaboratory intercalibration studies to improve the variability.

As a result of this effort a Guidance Manual was developed based on the lessons learned. The Copermittees will only contract laboratories that have participated in the intercalibration efforts for the purpose of improving and standardizing analytical methods. The Copermittees will continue to participate in future SMC intercalibration studies, as needed, in the next permit term. There is no monitoring plan associated with this activity; however the resulting guidance will be of benefit to future monitoring in the region. The Copermittees will only contract with laboratories that have participated in this effort.

Field Procedure Intercalibration

Prior to the spring bioassessment activities the SMC Regional Bioassessment Subcommittee Technical Subcommittee conducts a follow-up meeting on an annual basis to reflect upon the previous year's field efforts and coordination as well as review the procedures used under the 5-year workplan. This provides an opportunity to share lessons learned and initiate the preparations for the next year's efforts which are kicked-off by a field Intercalibration exercise. The Co-Permittee's contracted bioassessment services consultants participate in this effort. The observations from the past Intercalibration efforts have identified areas of the regional survey that need streamlining for efficient data collection. In general the observations have shown that the participating agencies' field crews are collecting data in a comparable manner and in general conformance with the available SWAMP protocols and program components outlined in the Regional Bioassessment Workplan. The Copermittees' field crews will continue to participate in this activity on an annual basis in the next permit term. Detailed proposed monitoring methods and procedures are presented in **Appendix 5A**.

5.4 PROJECT ORGANIZATION AND RESPONSIBILITIES

The Copermittees are collectively responsible for implementing the SMR WMA MAP. The RCFCWCD, as the Principal watershed Copermittee within the SMR WMA, is the lead agency responsible for overseeing implementation of the Middle SMR Subwatershed Monitoring Program. The County of San Diego is the lead agency responsible for overseeing implementation of the Lower SMR Subwatershed Monitoring Program.

5.4.1 Monitoring to Assess Progress Toward Achieving Goals and Schedules

This section summarizes monitoring to assess progress toward achieving goals related to the HPWQC (the dry weather condition of eutrophication impacts for the SMR Estuary and the year-round conditions of nutrient enrichment for Rainbow Creek). As outlined in **Section 4.2**, strategies to be implemented to demonstrate progress toward meeting goals to address eutrophication impacts in the SMR Estuary support Copermittees' efforts to reduce non-stormwater flows from Copermittees' MS4 outfalls.

5.4.1.1 Monitoring to Assess Progress Toward Achieving Goals and Schedules in the Middle SMR Subwatershed

A multi-tiered approach to setting goals was used for the Middle SMR Subwatershed. The six compliance pathways for Copermittees to meet the WQIP goals are detailed in **Section 4.1.3**. Each Copermittee in the Middle SMR Subwatershed will have the option of demonstrating compliance through one of the six pathways. The date by which the final goal for the Middle SMR Subwatershed must be achieved is preliminarily scheduled for 2038 and will be updated through the adaptive management process when the TMDL Alternative becomes effective. **Table 5-9** presents the compliance pathways for the Middle SMR Subwatershed goals and the monitoring that may be used to track progress toward achieving these goals.

Table 5-9 Monitoring Related to HPWQC – Eutrophication Impacts and Nutrient Loading, Middle Santa Margarita River Subwatershed Copermittees

	Compliance Pathway	Final Numeric Goal[1]	Monitoring Elements
1	Demonstration that the discharger is attaining the load reduction goal of 76% in the Middle SMR Subwatershed in receiving waters.	76% reduction in dry weather loadings in receiving waters	*Dry Weather Receiving Water Monitoring* data for total nitrogen and total phosphorus collected in the Santa Margarita River (receiving water) at the base of the Middle SMR Subwatershed.
	OR		
2	Demonstration that the Santa Margarita River Estuary targets (based on the proposed TMDL Alternative) have been attained.	Numeric goals to be determined based on outcome of TMDL Alternative for the Santa Margarita River Estuary	*TMDL Monitoring* in conjunction with other dischargers based on outcome of TMDL Alternative.
	OR		
3	Demonstration that non-stormwater flows that are within Copermittee control have been reduced to meet load reductions.	100% reduction in non-stormwater flows within Copermittee control (i.e., within their regulatory authority)	*Dry Weather Field Screening Monitoring* for flow at Copermittee major outfalls.
	OR		
4	Demonstration that discharger is meeting required load reductions as described in the TMDL Alternative for the SMR Estuary.	76% reduction in dry weather loadings from MS4 Copermittees	Total nitrogen, total phosphorus, and flow data from *Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring*.
	OR		
5	Demonstration that exceedances of targets are due to sources outside of Copermittee control.	Where final goals have not been met, demonstrate that exceedances of targets are due to source of nutrients outside of the control of the Copermittees.	Potential *Special Studies* conducted during future Permit terms.
	OR		
6	Demonstration that management actions to attain load or flow reductions are being implemented through mechanisms defined in the accepted Water Quality Improvement Plan.	The Copermittees assess progress to goals, implement the JRMP, enhanced JRMP strategies, optional jurisdictional strategies, or optional WMA strategies, as triggered through an iterative approach as described in the accepted Water Quality Improvement Plan.	N/A

1. The final goals are preliminary and will be updated through the adaptive management process when the TMDL Alternative becomes effective.

The outfall monitoring data identify if there are direct or indirect discharges from the Copermittees' MS4 outfalls to receiving waters during dry weather. Where discharges are found, analytical data

and flow can be assessed to determine if the concentrations of total nitrogen and total phosphorus exceed the effluent limitations. Combined with the flow data, these concentrations can also be used to calculate loading rates and flux per acre, and further extrapolated to calculate annual loading rates for the Middle SMR Subwatershed.

5.4.1.2 Monitoring to Assess Progress Toward Achieving Goals and Schedules in the Lower SMR Subwatershed

Multiple compliance pathways are set forth for the Rainbow Creek Nutrient TMDL in Attachment E.3 of the Permit. Compliance with the TMDL may be demonstrated via one of the compliance pathways identified in the Permit. The final compliance date for the TMDL is December 31, 2021, which will be during the next permit term. **Table 5-10** presents the compliance options for the Rainbow Creek Nutrient TMDL goals and the monitoring that may be used to track progress toward achieving these goals.

Table 5-10 Monitoring Related to HPWQC – Nutrients in Rainbow Creek, San Diego County[1]

	Compliance Pathway	TMDL Goal	Monitoring Elements
1	No discharge from MS4 outfalls	No direct or indirect discharge from the County of San Diego's MS4 outfalls to the receiving water	At least quarterly visual observation of flow from outfalls to receiving and Dry Weather Field Screening Monitoring.
		OR	
2	Meet final receiving water limitations	No exceedances of the final Receiving Water Limitations	*TMDL Monitoring* data for nitrate, total nitrogen, and total phosphorus collected at Rainbow Creek monitoring locations.
		OR	
3	Meet final effluent limitations	No exceedances of the final effluent limitations at the County of San Diego's MS4 outfalls	Nitrate, total nitrogen, and total phosphorus concentration data collected at outfalls as part of *Outfall Monitoring* and *Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring*.
		OR	
4	Reduce annual pollutant loads	The annual pollutant loads from given land uses discharging to and from MS4 outfalls do not exceed the final effluent limitations	The land uses are intermingled and cannot easily be independently monitored. This pathway is not currently addressed.
		OR	
5	Implement Water Quality Improvement Plan	Implement Water Quality Improvement Plan that incorporates the required BMPs supported by a reasonable assurance as accepted by the San Diego Regional Water Board	*See above for paths 1 through 3.* BMP effectiveness monitoring conducted once BMPs are constructed will demonstrate compliance.

1. See Order R9-2013-0001, as amended, Attachment E.3 – Total Maximum Daily Loads for Total Nitrogen and Total Phosphorus in the Rainbow Creek Watershed.

At this time, the County of San Diego plans to leverage current permit-required monitoring programs and augment these programs close to the compliance deadline to demonstrate dry

weather compliance for nutrients for both the SMR Estuary and Rainbow Creek. However, efforts will be accelerated in Rainbow Creek to meet the upcoming compliance deadline of December 31, 2021. Currently, the County inspects all MS4 outfalls in Rainbow Creek at least quarterly and conducts 24 –hour continuous monitoring from May through September at a minimum of one outfall location. These efforts will continue and when staff are available, the outfalls will be monitored monthly to demonstrate progress toward meeting the dry weather goal. Dry weather conditions occur in the watershed about 90 percent of the time during the year. The outfall monitoring data identify if there are direct or indirect discharges from the County of San Diego's MS4 outfalls to Rainbow Creek during dry weather.

For wet weather compliance monitoring in Rainbow Creek, BMP effectiveness monitoring will be used once the BMPs are constructed to demonstrate that the goal is met. This BMP monitoring will include the collection of water quality samples upstream and downstream of the constructed BMPs to measure the change in concentration or loads of nutrients and total suspended solids. In the meantime, for the Rainbow Creek Nutrient TMDL, at least one additional wet weather outfall monitoring event will be added annually as part of the MS4 Outfall Wet Weather Monitoring (**Section 5.3.2.1**) to provide additional characterization data to inform the design of the remedial measures. This additional wet weather outfall monitoring will be selected during the design phase of the structural BMP and tailored to the needs of the engineers for the design of the BMP. The outfall monitoring will be conducted to collect flow-weighted composites, time-weighted composites, or to collect separate aliquots of samples during one part of the storm event, such as during the rising limb of the storm hydrograph. These samples will be analyzed, at a minimum, for nutrients and total suspended solids.

To track progress toward meeting the dry weather goal for the SMR Estuary, the County of San Diego will expand the Dry Weather Field Screening Monitoring (**Section 5.3.2.2**) to major outfalls that discharge to the SMR from semiannually to quarterly to record flow as present, ponded water or no flow. This additional information will further inform the prioritization of outfalls to mitigate potential sources of dry weather flows.

5.5 REPORTING AND ASSESSMENT PROGRAM

The Copermittees will submit a WQIP Annual Report for each reporting period no later than January 31st of the following year. The annual reporting period will consist of two different periods: 1) July 1st to June 30th for JRMP and WQIP implementation, and 2) October 1st to September 30th for the monitoring and assessment programs. The WQIP Annual Reports will be made available to the public via two Regional Clearinghouses (i.e., RCFCWCD and Project Clean Water websites). The following sections detail the information and assessments that will be provided within the WQIP Annual Report or the Report of Waste Discharge (ROWD) that the Copermittees will submit 180 days prior to the end of the permit term.

5.5.1 Water Quality Improvement Plan Annual Reporting Requirements

The Permit sets forth annual reporting requirements for the WQIP Annual Report. Copermittees will provide the following information within the WQIP Annual Report:

- Receiving water and MS4 outfall discharge monitoring data;
- Progress, finding, interpretations, and conclusions of the special studies (or phases of the study), as appropriate;

- Findings, interpretations, and conclusions from the assessments detailed within **Section 5.5.2**;
- Progress of implementing the WQIP, including but not limited to, the following:
    - Progress toward achieving the interim and final numeric goals for the HPWQC for the WMA;
    - Water quality improvement strategies that were implemented and/or no longer implemented by each of the Copermittees during the reporting period and previous reporting periods;
    - The water quality improvement strategies planned for implementation during the next reporting period;
    - Proposed modifications to the water quality improvement strategies, the public comments received, and the supporting rationale for the proposed modifications;
    - Previous modifications or updates incorporated into the WQIP and/or each Copermittee's JRMP document and implemented by the Copermittees in the WMA; and
    - Proposed modifications or updates to the WQIP and/or each Copermittee's JRMP document;
- Completed JRMP Annual Report form for each Copermittee in the WMA;
- Copermittee monitoring data utilized in developing the WQIP Annual Report uploaded to the California Environmental Data Exchange Network (CEDEN). Raw data files will not be included within the WQIP Annual Report.

5.5.2 Assessment Program

The assessment portion of the MAP will evaluate the data collected under the monitoring programs described in **Section 5.2**, as well as the information collected as part of the JRMPs and implementation of WQIP strategies. The data collected from these programs will be used to assess the progress toward achieving the numeric goals and schedules for addressing the HPQWC. **Figure 5-8** depicts how the watershed monitoring activities will support the assessments required by the Permit. Some assessments will be reported annually, as part of the WQIP Annual Report, while others will be included in the ROWD. The SMR WMA MAP will be evaluated and adapted in the context of the WQIP Annual Report and the ROWD. The re-evaluation will consider data gaps and the results of all monitoring program elements. In general, short term evaluations will be included in annual reports, with long term assessments included within the ROWD. The assessment process and feedback loop is described in greater detail in **Chapter 6**, Adaptive Management.

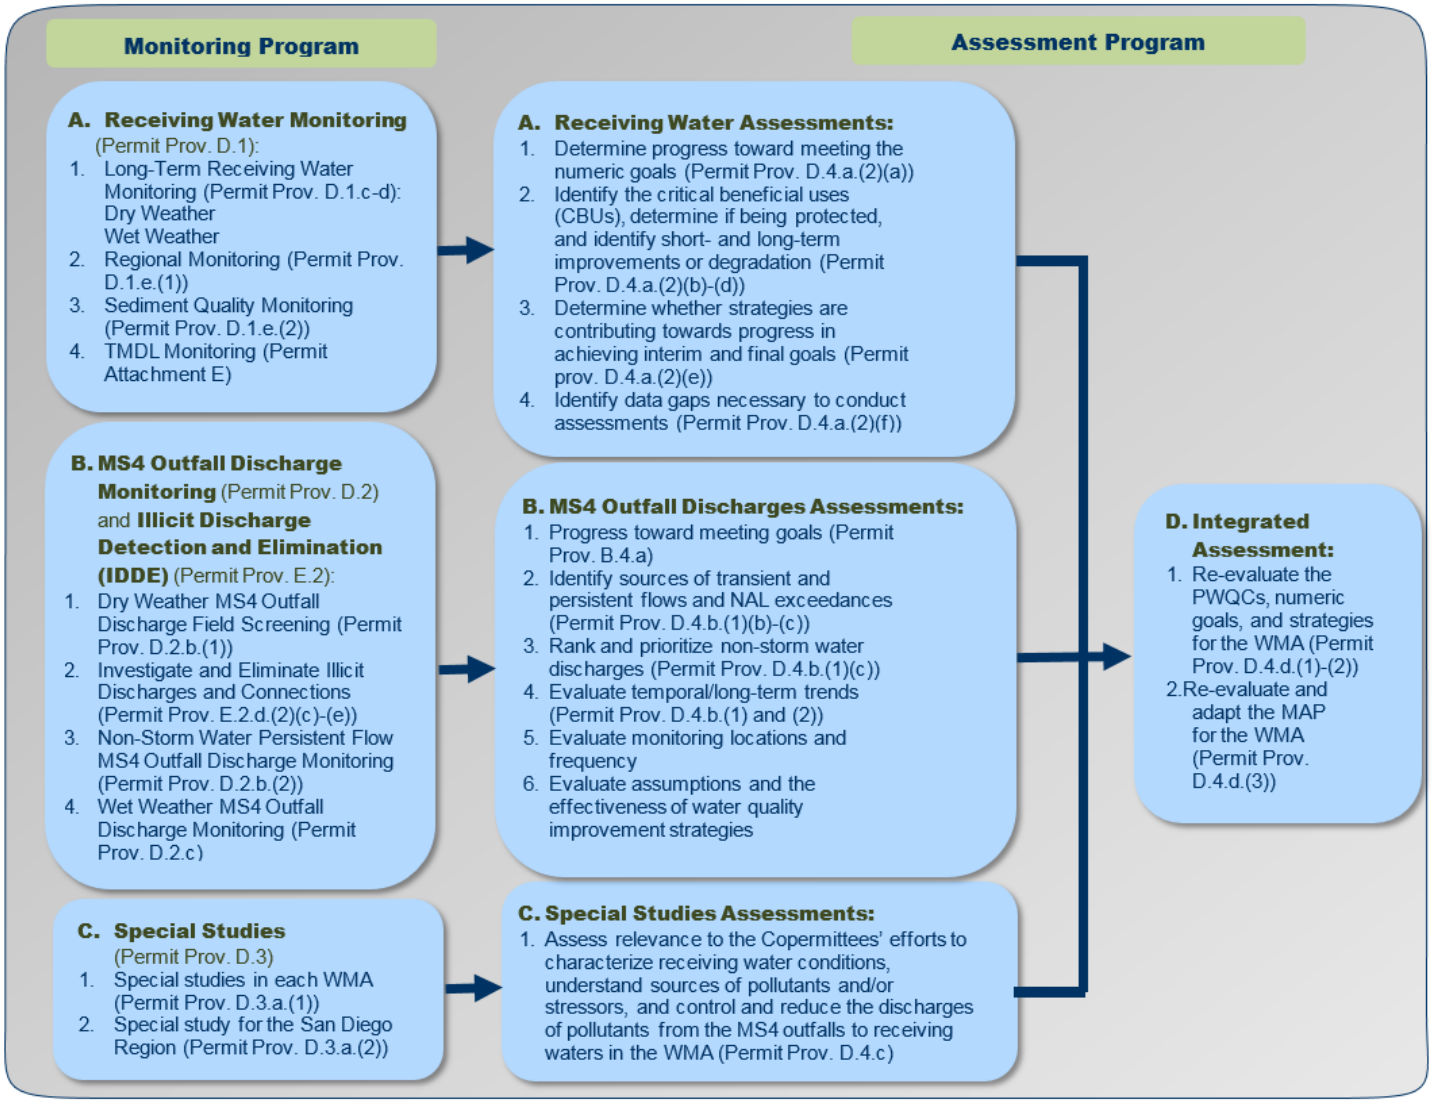

Figure 5-8. MAP Components for the SMR WMA

5.5.2.1 RECEIVING WATER ASSESSMENT

The assessment of receiving waters involves evaluating the physical, chemical, and biological conditions of the receiving waters and sediments. The Copermittees must assess the status and trends of receiving water quality conditions in coastal waters, enclosed bays, estuaries, and streams in the watershed. Receiving water data, regional monitoring programs, sediment quality, and TMDL monitoring programs will be used as applicable. The receiving water assessments to be presented in the WQIP Annual Report or ROWD will:

- Assess whether or not the conditions of the receiving waters are meeting the applicable numeric goals by calculating the percent reduction in dry weather loading in receiving waters;
- Identify the most critical beneficial uses (e.g., HPWQC) that must be protected to ensure the overall health of the receiving water by following procedures consistent with the evaluations outlined in **Chapter 2**;
- Evaluate whether or not those critical beneficial uses are being protected by comparing data to applicable water quality objectives;
- Identify short-term and/or long-term improvements or degradation of those critical beneficial uses by evaluating trends;
- Consider whether or not the WQIP strategies contribute toward progress in achieving the interim and final numeric goals of the WQIP; and
- Identify data gaps in the monitoring data needed to assess the provisions above.

5.5.2.2 MS4 OUTFALL DISCHARGE ASSESSMENTS

The MS4 outfall discharge assessments include evaluating both the dry weather monitoring data associated with the IDDE program collected as part of the JRMP and the wet weather monitoring data collected by the Copermittees. Each Copermittee will assess its dry weather MS4 outfall monitoring programs individually and compile results annually as part of the WQIP Annual Report. Each Copermittee must assess and report the progress of its IDDE program (required pursuant to Permit Provision E.2) toward effectively prohibiting non-storm water and illicit discharges into the MS4s within its jurisdiction. The non-storm water discharge reduction assessments to be presented in the WQIP Annual Report or ROWD will:

- Identify known and suspected controllable sources (e.g. facilities, areas, land uses, pollutant generating activities) of transient and persistent flows within the Copermittee's jurisdiction in the WMA by following procedures consistent with the procedures outlined in **Chapter 3**;
- Identify sources of transient and persistent flows within the Copermittee's jurisdiction in the WMA that have been reduced or eliminated by reviewing information collected as part of the IDDE program and Dry Weather MS4 Outfall Discharge Field Screening Monitoring Program;
- Identify necessary modifications through program assessment to identify and eliminate sources of persistent flow;

- Rank the outfalls according to potential threat to receiving water quality and produce a prioritized outfall list;
- For the highest priority outfalls in exceedance of NALs,
    - Identify known and suspected sources that may cause or contribute to NAL exceedances;
- Using a model or other method, calculate/estimate non-storm water volumes and pollutant loads from all major outfalls with persistent flow to assess progress toward meeting flow reduction and load reduction goals identified in **Section 4.1.3**:
    - With an estimate of the percent contribution from each known source for each MS4 outfall; and
    - Each Copermittee must annually identify and quantify sources of non-storm water not subject to the Copermittee's legal authority that are discharged from the Copermittee's major MS4 outfalls to downstream receiving waters;
- Identify reductions and progress in achieving reductions in non-storm water and illicit discharges to the Copermittee's MS4 in the WMA;
- Assess the effectiveness of water quality improvement strategies (with estimates attributable to the specific strategies if possible) toward addressing MS4 non-storm water discharges by comparing data collected through the Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring Program to NALs and assessing additional available information;
- Identify modifications to increase effectiveness of the water quality improvement strategies; and
- Identify data gaps in the monitoring data necessary to assess the provisions above.

The assessments for stormwater pollutant discharge reductions to be presented in the Annual Report will:

- Use a model or other method to calculate/estimate:
    - The average storm water runoff coefficient for each land use within the WMA;
    - The volume of storm water and pollutant loads discharged from monitored outfalls for each storm event with measurable rainfall greater than 0.1 inch;
    - The total flow volume and pollutant loadings discharged from each jurisdiction within the WMA over the course of the wet season (extrapolated from the monitored MS4 outfalls); and
    - The percent contribution of storm water volumes and pollutant loads discharged from each land use type within each hydrologic subarea with a major MS4 outfall to receiving waters or within each major MS4 outfall to receiving waters in the Copermittee's jurisdiction within the WMA for each storm event with measurable rainfall greater than 0.1 inch;
- Evaluate findings against analyses/assumptions from the WQIP to determine whether updates are needed;

- Identify reductions in pollutants concentrations or loads from different land uses and/or drainage areas;
- Assess the effectiveness of water quality improvement strategies (with estimates attributable to the specific strategies if possible) toward reducing pollutants in storm water discharges by comparing data collected through the MS4 Outfall Wet Weather Monitoring Program to storm water action levels (SALs) identified in Permit Provision C.2 [inclusive of any future iterations] and assessing additional available information;
- Identify modifications to increase effectiveness of the water quality improvement strategies;
- Identify data gaps in the monitoring data necessary to assess the provisions above; and
- Evaluate all the wet weather MS4 outfall discharge monitoring data, and incorporate new outfall monitoring data into time series plots for each long-term monitoring constituent for the WMA, and perform statistical trends analysis on the cumulative long-term wet weather MS4 outfall discharge water quality dataset.

5.5.2.3 SPECIAL STUDIES ASSESSMENTS

As part of the WQIP Annual Report, the Copermittees will evaluate the results and findings from the special studies, as available. Depending on the special study, the results may be included in assessments related to receiving waters, MS4 discharges, source identification, or other evaluations, as appropriate. Where applicable, they will use the resulting data to: (1) assess their relevance to the Copermittees' characterization of receiving water conditions, (2) understand sources of pollutants and/or stressors, and (3) control and reduce the discharges of pollutants from the MS4 outfalls to receiving waters. As with the other monitoring programs, the results of the special studies assessment may warrant modifications of or updates to the WQIP.

5.5.2.4 INTEGRATED ASSESSMENT

The Copermittees will integrate the data collected as part of the MAP, along with information collected during the implementation of the JRMP and WQIP strategies. The integrated assessment will evaluate the main components of the WQIP and will follow the assessment process outlined in the Permit. The integrated assessment will include all four WQIP components: (1) Priority Water Quality Conditions, (2) Goals and Schedules, (3) Strategies and Schedules, and (4) MAP. The assessment will be performed during the development of the ROWD and include those assessments specified for "once during the term of the Order". The PWQCs will be reevaluated using the receiving water and MS4 outfall discharge assessments. The goals and schedules in **Chapter 4** will be reviewed based on the results of the receiving water and MS4 outfall discharge assessments, along with data collected as part of the JRMP and WQIP strategies. This evaluation will highlight the progress in achieving the compliance goals. Both water quality monitoring data and maintenance/observational data related to BMP effectiveness will be used to assess the strategies implemented by the Copermittees. Strategies will be evaluated in the WQIP Annual Report based on the data collected as part of the JRMP and WQIP strategies and any new relevant BMP effectiveness data collected by the Copermittees. Finally, the Copermittees must re-evaluate and adapt the MAP for the WMA when new information becomes available to improve the MAP. The re-evaluation of the MAP for the WMA will consider the data gaps identified by the assessments described in **Sections 5.5.2.1** and **5.5.2.2** and results of the special studies.

6 Iterative Approach and Adaptive Management Process

Chapter 6 outlines the iterative approach of the adaptive management process that will be used to evaluate and adapt the WQIP for the SMR WMA. The adaptive management process is the framework to evaluate progress and make adjustments in implementation approaches and timing to attain goals. It will be used, in conjunction with data collected, as part of the Monitoring and Assessment Program (MAP), to evaluate whether modifications to goals, schedules, and/or strategies are necessary to meet the interim and final goals for eutrophication impacts and nutrient loading in the SMR WMA. Through the implementation of strategies and an iterative, adaptive management approach, it is anticipated that the numeric goals will be achieved and the water quality will be improved. **Figure 6-1** summarizes the framework of the adaptive management process.

The WQIP will be adapted in response to triggers identified in Permit Provisions B.5.a-c. Triggers that may warrant program adaptation include exceedances of water quality standards in receiving waters, new information, Regional Water Board recommendations, and input received during the public participation process. The Regional Water Board may require updates to the WQIP based on information they receive from outside parties. Additional Permit requirements for adaptive management are summarized in **Table 6-1**. Effectiveness assessments of JRMP or LIP programs and strategies may also trigger adaptations to the WQIP. The diagram below outlines the process for the development and implementation of the WQIP and includes the iterative approach and adaptive management process steps.

Each trigger calls for specific responses within timeframes specified in the Permit. While the adaptive management process would typically be implemented annually or at the end of the permit term, other adaptations could occur on a different schedule.

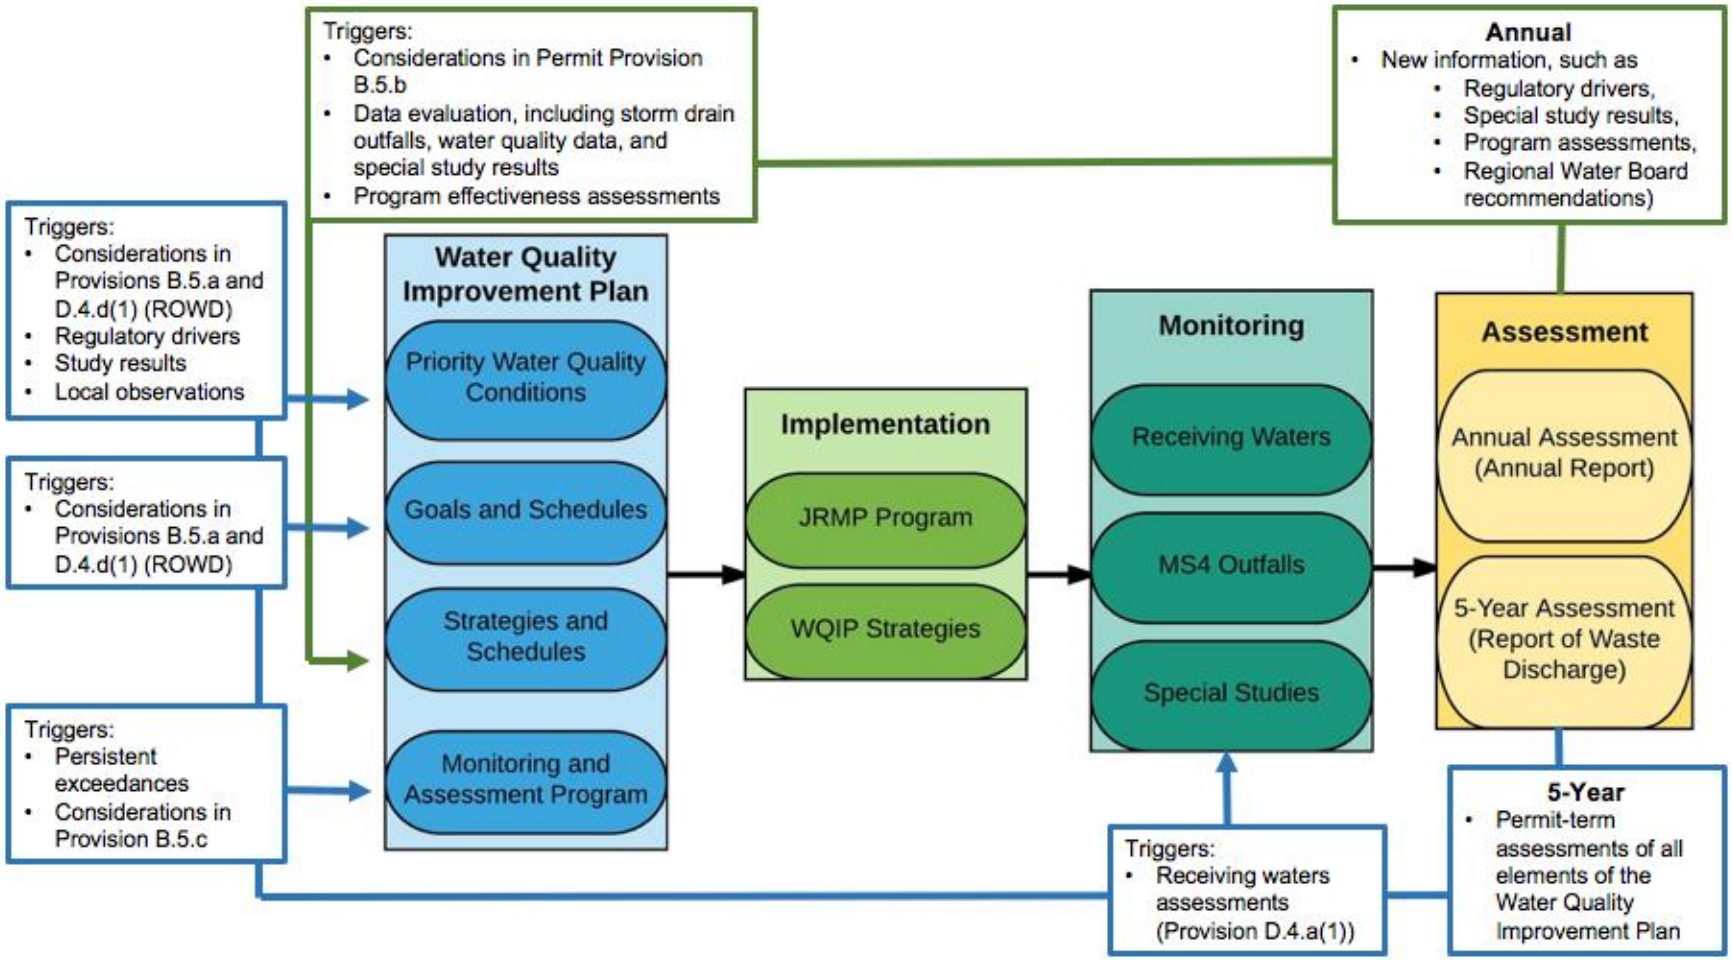

Figure 6-1. Adaptive Management Process Framework

Table 6-1. Permit Requirements for the Adaptive Management Process

Permit Provision	Requirements	Frequency
Provision A.4	The Water Quality Improvement Plan must be designed and adapted to ultimately achieve compliance with the discharge prohibitions (Provisions A.1.a and A.1.c) and receiving water limitations (Provision A.2.a) specified in the Permit.	Report of Waste Discharge
Provision B.5	Specific considerations must be included in the adaptive management process. This includes the re-evaluation of PWQCs; adaptation of goals, strategies, and schedules; and adaptation of the Monitoring and Assessment Program.	Re-evaluation of Water Quality Conditions, Goals/Schedules, and the Monitoring and Assessment Program to be provided in Report of Waste Discharge; Strategies and Schedules to be considered annually.
Provision D.4.d	Contains the processes for the assessments and adaptive management that must occur once during the Permit term.	Report of Waste Discharge
Provision F.2.c	Describes the requirements for updates to the Water Quality Improvement Plan that could result from implementation of the adaptive management requirements.	Copermittees must submit updates to the Water Quality Improvement Plan either in the Annual Report or in the Report of Waste Discharge

6.1 RE-EVALUATION OF PRIORITY WATER QUALITY CONDITIONS

Permit Provision B.5.a describes the process for re-evaluation of the PWQCs. PWQCs may be re-evaluated as needed by the Copermittees during the permit term, and must be re-evaluated in the Report of Waste Discharge. The HPWQC and PWQCs selected during the development of the WQIP are intended to remain for the duration of the permit term, but may be adjusted if new, pertinent information becomes available that would directly influence priorities. Provisions B.5.a and D.4.d(1) describe the considerations that would trigger an assessment of the PWQCs and HPWQC. The following additional considerations may trigger an assessment of the PWQCs and HPWQC, including, but not limited to:

- Regulatory drivers, such as revised WQOs issued by the State Water Board, approval of a TMDL Basin Plan Amendment, modifications to the TMDL Alternative, and/or adoption of the TMDL Alternative Resolution;
- Results of special studies conducted within the watershed, and relevant results from outside the watershed related to the PWQCs and HPWQC;
- Additional relevant and appropriately collected data and information related to the Upper SMR Subwatershed, including data to be collected at the new monitoring station described in Section 5.3.1;

- New data and recommendations developed from the Rainbow Creek Nutrient TMDL Monitoring and assessment of progress toward achieving goals and schedules in the Lower SMR Subwatershed; and
- Local observations, such as the number of homeless encampments in creek systems, or local evidence of eutrophication.

Data collected during the permit term will be used to update the analysis of the PWQCs as part of the Report of Waste Discharge**. Table 6-2** lists the considerations that must be included when Copermittees re-evaluate the PWQCs for the watershed.

Table 6-2. Re-evaluation of Priority Water Quality Conditions

Frequency	Trigger[1]	Considerations
5-Years	Report of Waste Discharge (B.5.a, D.4.d(1))	***Provision B.5.a Iterative Approach and Adaptive Management Considerations*** • Achievement of the outcome of improved water quality through the implementation of strategies identified in the Water Quality Improvement Plan. • New information developed in the re-assessment of receiving water conditions, impacts from MS4 discharges, and subsequent re-evaluation of priorities. • Spatial and temporal accuracy of monitoring data. • Availability of new information and data from sources outside the JRMP programs that inform the effectiveness of strategies and actions. • Recommendations from the Regional Water Board. • Recommendations received through a public participation process.
		Provision D.4.d(1) Integrated Assessment Considerations • Re-evaluation of the receiving water conditions and the impacts of MS4 discharges on receiving waters per the process developed in **Chapter 2**. This includes the identification of beneficial uses in receiving waters that are protected per the Monitoring and Assessment Program. • Re-evaluation of the identification of stormwater conveyance sources and/or stressors if corresponding to elevation of a new highest priority condition.

1. Following approval of a TMDL with wasteload allocations by the Office of Administrative Law (OAL) and the USEPA, the Copermittees must initiate an update of the WQIP within six months – this may impact the PWQCs and HPWQC for the SMR WMA.

6.2 ADAPTATION OF GOALS, STRATEGIES, AND SCHEDULES

The adaptation of goals, strategies, and schedules must occur as part of the Report of Waste Discharge, and may occur on an annual basis under certain conditions. The two conditions that warrant annual adaptation of goals and schedules are: (1) where a new TMDL is approved by the State of California Office of Administrative Law (OAL) and the USEPA or (2) where annual evaluations of receiving water and MS4 outfall monitoring data provide new information impacting the goals. The three conditions that warrant annual adaptation of strategies and

schedules are: (1) where a new TMDL is approved by OAL and USEPA, (2) where annual evaluations of receiving water and MS4 outfall monitoring data provide new information impacting implementation schedules, or (3) where program effectiveness assessments provide information adequate to justify modification.

6.2.1 Adaptation of Goals and Schedules

As part of the preparation of the Report of Waste Discharge, the Copermittees will evaluate the progress toward achieving the watershed goals established in **Chapter 4**. The watershed goals and schedules that will be assessed as part of the Report of Waste Discharge are provided in **Table 4-2** in **Section 4.1**.

Assessment of the watershed goals and compliance pathways will be performed using data collected per the Monitoring and Assessment Program (MAP) and JRMP/LIPs, along with the schedules developed in conjunction with each goal. Depending on the results of the assessment, it may be appropriate to adjust either the numeric goals and/or the schedules associated with each goal. The ability to modify goals and schedules based on the TMDL Alternative for the SMR Estuary will be dependent on the flexibility afforded by the Resolution for the TMDL Alternative, which has yet to be adopted by the Regional Water Board. **Table** 6-3 lists the considerations that will be included in the process of evaluating progress towards defined goals and schedules.

Table 6-3. Adaptation of Goals and Schedules for the HPWQC

Frequency	Trigger [a]	Considerations
5-Years	Report of Waste Discharge (B.5.b, D.4.d.(1))	***Provision B.5.b Iterative Approach and Adaptive Management Considerations*** • Modifications to the PWQCs based on Provision B.5.a. • Progress toward achieving numeric goals for the highest priority water quality conditions. • Progress in meeting established schedules. • New policies or regulations that may affect goals. • Reductions of non-storm water discharges. • Reductions of pollutants in storm water discharges from the stormwater conveyance to the MEP. • New information resulting from the re-evaluation of impacts from MS4 discharges and/or pollutants and stressors. • Efficiency in implementing the Water Quality Improvement Plan. • Recommendations from the Regional Water Board. • Recommendations received through a public participation process. ***Provision D.4.d(1) Integrated Assessment Considerations*** • Evaluation of the progress toward achieving interim and final numeric goals for protecting impacted beneficial uses in receiving waters.

1. Following approval of a TMDL with wasteload allocations by OAL and the USEPA, the Co-Permittees must initiate an update of the WQIP within six months.

6.2.2 Adaptation of Strategies and Schedules

The strategies and implementation schedules developed to address the HPWQC in the watershed will be re-evaluated as part of the Annual Reporting process and the preparation of the Report of Waste Discharge. These re-evaluations may result in modifications to or elimination of strategies as well as the development of new strategies. Ultimately, the effectiveness of the strategies will be based on the progress toward achieving the interim and final numeric goals. However, an evaluation of strategies based on the achievement of the interim and final numeric goals may take many years of implementation and monitoring to assess. To supplement the "goal-based" assessments, programmatic data collected over the permit term may be incorporated into the assessment and adaptive process to modify strategies and implementation schedules as appropriate.

6.2.2.1 Water Quality Data Evaluation and Linkage to Strategies

Receiving water data will be assessed as described in **Section 5.5**. The assessment will indicate progress toward longer term goals and protection of beneficial uses. These data may be used to evaluate the collective effectiveness of the strategies. This information will provide a "big picture" assessment of the success of the strategies over the long term. The data evaluation also has the potential to trigger mandatory updates to the WQIP per Permit Provision A.4 where exceedances of water quality standards persist in receiving waters. This part of the adaptive management process is described further in **Section 6.5** and detailed in **Figure 6-1.**

MS4 outfall visual observations, water quality data, and special study results may provide information that is more directly linked to the implementation of individual strategies. Where possible, this information will be used to modify, eliminate, and/or develop new strategies to address the HPWQC in the watershed. Where appropriate, these assessments will include a comparison of the data with the NALs and SALs as required per Provision C of the Permit. These data will provide the foundation for the MS4 outfall discharge assessments described in **Chapter 5**, which will examine the results of Illicit Discharge Detection and Elimination Programs and MS4 Outfall Discharge Monitoring Programs. Where strategies can be linked to measurable or demonstrable reductions of non-storm water discharges or to reductions of pollutants in storm water, appropriate modifications will be made.

6.2.2.2 Program Assessments

Where available, the results of program effectiveness assessments performed at the jurisdictional or watershed scale may also factor into the adaptation of specific strategies. The level of information will vary by jurisdiction and by program, as these types of assessments are not explicitly required by the Permit. However, in many cases, the jurisdictions are performing programmatic assessments to ensure the most effective use of available resources. These assessments have the potential to provide information to determine the effectiveness of specific strategies that is more relevant than water quality data collected at MS4 outfalls or in receiving waters and may be a key driver in adapting strategies. In some cases, modifications to strategies may also be the result of internal jurisdictional opportunities or constraints such as increases or decreases in available funding or staffing. Modifications to strategies based on program effectiveness assessment may occur annually or on a permit term.

Table 6-4 lists the considerations that will be evaluated when adapting strategies and schedules, whether on an annual timeframe within the Annual Report or on a 5-year permit term timeframe (i.e., Report of Waste Discharge).

Table 6-4. Adaptation of Water Quality Strategies and Schedules

Frequency	Trigger[1]	Considerations
Annual	New Information (B.5.b)	***Permit Provision B.5.b Iterative Approach and Adaptive Management Considerations*** • Modifications to the priority water quality conditions. • Progress toward achieving numeric goals for the highest priority water quality conditions. • Progress in meeting established schedules. • New policies or regulations that may affect goals. • Reductions of non-storm water discharges. • Reductions of pollutants in storm water discharges from the stormwater conveyance to the maximum extent practicable (MEP). • New information resulting from the re-evaluation of impacts from MS4 discharges and/or pollutants and stressors. • Efficiency in implementing the Water Quality Improvement Plan. • Recommendations from the Regional Water Board. • Recommendations received through a public participation process.
5-Years	Report of Waste Discharge (D.4.d.(2))	***Permit Provision D.4.d(2) Integrated Assessment Considerations*** • Identification of the non-storm water and storm water pollutant loads from the MS4 outfalls per Provision D.4.b. • Identification of the non-storm water and storm water pollutant load reductions, or other improvements that are necessary to attain the interim and final numeric goals. • Identification of the non-storm water and storm water pollutant load reductions, or other improvements, that are necessary to demonstrate that non-storm water and storm water discharges are not causing or contributing to exceedances of receiving water limitations. • Evaluation of the progress of the strategies toward achieving interim and final numeric goals for protecting beneficial uses in receiving waters.
5-Years	Persistent Exceedances Not Addressed (A.4.a.(2))	***Permit Provision A.4.a(2) Integrated Assessment Considerations*** [2] • Water quality standard exceedances for pollutants that are addressed by the Water Quality Improvement Plan; implementation of the accepted plan continues and is updated as necessary. • If MS4 discharges are causing or contributing to a new exceedance of an applicable water quality standard for pollutants that are not addressed by the Water Quality Improvement Plan, the Water Quality Improvement Plan will be updated as part of the Annual Report (unless directed to update it earlier by the Regional Water Board). Following Regional Water Board approval of modifications to the Water Quality Improvement Plan, the Copermittees must update their JRMP accordingly.

1. Following approval of a TMDL with wasteload allocations by the OAL and the USEPA, the Copermittees must initiate an update of the WQIP within six months.
2. The procedure need not be repeated for continuing or recurring exceedances of the same water quality standard(s) once scheduled strategies are implemented unless directed to do so by the Regional Water Board.

6.3 ADAPTATION OF MONITORING AND ASSESSMENT PROGRAM

As part of the Report of Waste Discharge, the Copermittees will consider modifications to the Monitoring and Assessment Program (MAP), consistent with the requirements in Permit Provision D.4.d.(3). During the permit term, modifications must be consistent with the requirements of Permit Provisions D.1, D.2, and D.3 (receiving water, MS4 outfall, and special study monitoring requirements, respectively), which limit the amount of adaptation that is possible. However, recommendations within the Report of Waste Discharge provide an opportunity to make more meaningful modifications to the Monitoring and Assessment Program. Examples of modifications to the Monitoring and Assessment Program include the following adjustments:

- Determine whether discharges from the MS4 outfalls are linked to exceedances in the receiving water;
- Address data gaps via re-assessment of monitoring locations and frequencies; and/or
- Address results of special studies.

Table 6-5 lists considerations that will be evaluated when adapting the Monitoring and Assessment Program.

Table 6-5. Adaptation of Monitoring and Assessment Program

Frequency	Trigger [1]	Considerations
Annual	New Information (B.5.c)	***Permit Provision B.5.c Iterative Approach and Adaptive Management Considerations*** • Re-evaluation based on new information such as modified priority water quality conditions, goals, strategies, or schedules. • New information, including new regulations. • Must include information gained from Permit required monitoring.
5-Years	Persistent Exceedances Not Addressed (A.4.a.(2))	***Permit Provision A.4.a(2) Integrated Assessment Considerations*** [2] May include modifying the monitoring program to fill data gaps. Modifications could include moving monitoring locations, adding additional sample collection, or changing type of sample collected.
5-Years	Report of Waste Discharge (B.5.c)	***Permit Provision B.5.c Iterative Approach and Adaptive Management Considerations*** • Review of Program based on the requirements in Provision D. • Adjustment of the monitoring program to determine whether discharges from the stormwater conveyance are causing/contributing to exceedances in the receiving water when new exceedances persist; identification and addressing of data gaps via re-assessment of monitoring locations and frequencies; adjustment of monitoring program to address results of special studies.

1. Following approval of a TMDL with wasteload allocations by the OAL and the USEPA, the Copermittees must initiate an update of the WQIP within six months.
2. The procedure need not be repeated for continuing or recurring exceedances of the same water quality standard(s) once scheduled strategies are implemented unless directed to do so by the Regional Water Board.

6.4 TIMING OF ADAPTIVE MANAGEMENT REQUIREMENTS

Adaptive management via the iterative process, based on the Permit-required evaluations described previously, will be integral to the success of the WQIP. However, the Copermittees will adapt different components of the WQIP at different rates, depending on a variety of factors. In most cases, annual modifications will consist of updates to strategies or timelines, reflective of information gained through implementation. Significant updates to the WQIP may be required as part of the Report of Waste Discharge, performed once per permit term. For parts of the WQIP (e.g., PWQCs, goals) a longer timeline is appropriate for evaluation, as accurate and more robust information is necessary to change the course of the WQIP. The following sections provide more insight and details related to the timing of the adaptive management process and the impacts on revisions to the WQIP.

6.4.1 Annual Assessments and Adaptive Management

The Permit indicates that new information should be considered on an annual basis for adaptations to the WQIP. Modifications may be appropriate for the water quality goals, strategies, schedules, and/or Monitoring and Assessment Program. The PWQCs and Monitoring and Assessment Program may be modified as needed during the permit term, but would likely be modified only as a result of assessments conducted for the Report of Waste Discharge.

6.4.1.1 Annual Evaluation of New Information

The adaptive management process may be triggered as new information becomes available as discussed in the following subsections. Where appropriate, modifications may be made to goals, strategies, schedules, and/or the Monitoring and Assessment Program and reported in the Annual Report.

6.4.1.1.1 Regulatory Drivers

Where new regulations or policies are adopted that impact watershed planning and implementation processes in the near term, modifications to the goals, strategies, schedules, and/or Monitoring and Assessment Program may be warranted, and, in some cases, required. For example, an update will be initiated no later than six months following approval of a TMDL Basin Plan Amendment by the OAL and the USEPA, or adoption of the TMDL Alternative Resolution. The trigger applies to TMDLs containing wasteload allocations assigned to Copermittees within the watershed during the term of the Order (Provision F.2.c.(2)). Similarly, modifications to the TMDL Alternative, in development during preparation of the WQIP, may also necessitate adaptations. The WQIP is based on the best available information related to the TMDL Alternative at the time of development, but modifications to the TMDL Alternative during the adoption process may necessitate modifications to the WQIP.

Other examples of regulatory drivers that may trigger modifications include new state policies or plans (e.g., biostimulatory substances amendments, biological objectives) and changes resulting from modifications to existing Permit requirements (e.g., as a result of revising a TMDL).

6.4.1.1.2 Special Study Results

As part of the Monitoring and Assessment Program, Copermittees have performed special studies related to the HPWQC for the watershed. As further described in **Chapter 5** of this WQIP, the Copermittees supported a WMA special study which consisted of providing in-kind monitoring

support for Phase II of the SMRNIG Characterization Studies. In addition, the Copermittees participated in the San Diego Regional Stream Reference Study, which included the collection and reporting of nutrient data. Future special studies will be designed to provide information related to sources of the HPWQC within the watershed, will be implemented during the permit term, and are typically performed over multiple years. As relevant data, conclusions, and lessons learned become available from these studies, the WQIP may be modified. The study results may impact the goals, strategies, schedules, and the Monitoring and Assessment Program. Additionally, lessons learned and study results from outside the watershed, especially those related to the HPWQC, may also be incorporated into the WQIP.

6.4.1.1.3 Program Assessments

WQIP strategies will be incorporated into individual Copermittees' JRMPs. The Copermittees will implement program refinements to increase focus on the particular water quality issues identified in the WQIP, and utilize various assessment methods to determine which program refinements are effective and which are not. The program effectiveness assessment results would provide useful information that may lead to adaptation of goals, strategies, schedules, and the Monitoring and Assessment Program. For example, as various water conservations strategies are implemented in coordination with water districts in target areas, the water conservation strategies that are found to be effective at reducing flow may be expanded, while those that are ineffective may be modified, reduced, or eliminated.

6.4.1.1.4 Regional Water Board Recommendations

Adaptation of the WQIP may also be required based on recommendations from the Regional Water Board. The Regional Water Board may require updates to the WQIP based on information they receive from outside parties. The Regional Water Board's recommendations could be a result of the public participation process, Consultation Committee input, review of submitted reports, or other Regional Water Board interests.

6.4.2 Permit Term Assessments and Adaptive Management

The Permit also contains specific assessments to be performed during preparation of the Report of Waste Discharge. These assessments are longer term in nature, occurring only once during the permit cycle. During Report of Waste Discharge preparation, all elements of the WQIP are eligible for modifications through the required adaptive management processes. Elements that could be evaluated include the water quality conditions (i.e., priorities), goals and accompanying schedules, strategies and accompanying schedules, and the Monitoring and Assessment Program.

6.4.2.1 Receiving Waters Assessments

Evaluation of receiving water and MS4 outfall discharge data will be performed annually as part of the Annual Report and is described in **Chapter 5**. More comprehensive evaluations of receiving water data will be performed for the Report of Waste Discharge (Permit Provision D.4.a.(1)). These evaluations will summarize receiving water data collected within the watershed and provide information with the potential to trigger the adaptive management process to achieve compliance with Permit discharge prohibitions and receiving water limitations as required in Provision A.

Provision A.4 describes adaptive management procedures that the Copermittees must implement "if exceedance(s) of water quality standards persist in receiving waters." If the adaptive

management process is triggered under this provision, the process will include the following assessments:

- Whether the MS4 outfall is a source of pollutants causing the exceedances to persist in the receiving waters, and
- Whether or not the exceedances are addressed by the WQIP.

If the receiving water exceedances are addressed under the WQIP, the Copermittees will continue implementation. If the receiving water exceedances are not addressed, the Copermittees will update the WQIP to address the exceedances as described in Provision A.4.a.(2) and submit the updates with the Report of Waste Discharge. The updates will include, as applicable:

- A description of strategies that are currently being implemented, are effective, and will continue,
- A description of strategies that will be implemented to reduce or eliminate pollutants or conditions that are a source of the receiving water exceedances,
- Updates to the implementation schedules for existing, revised, or additional strategies, and
- Updates to the Monitoring and Assessment Program to track progress toward achieving compliance with Provisions A.1.a, A.1.c, and A.2.a.

The adaptive management process as required under Provision A.4 is illustrated in **Figure 6-2**.

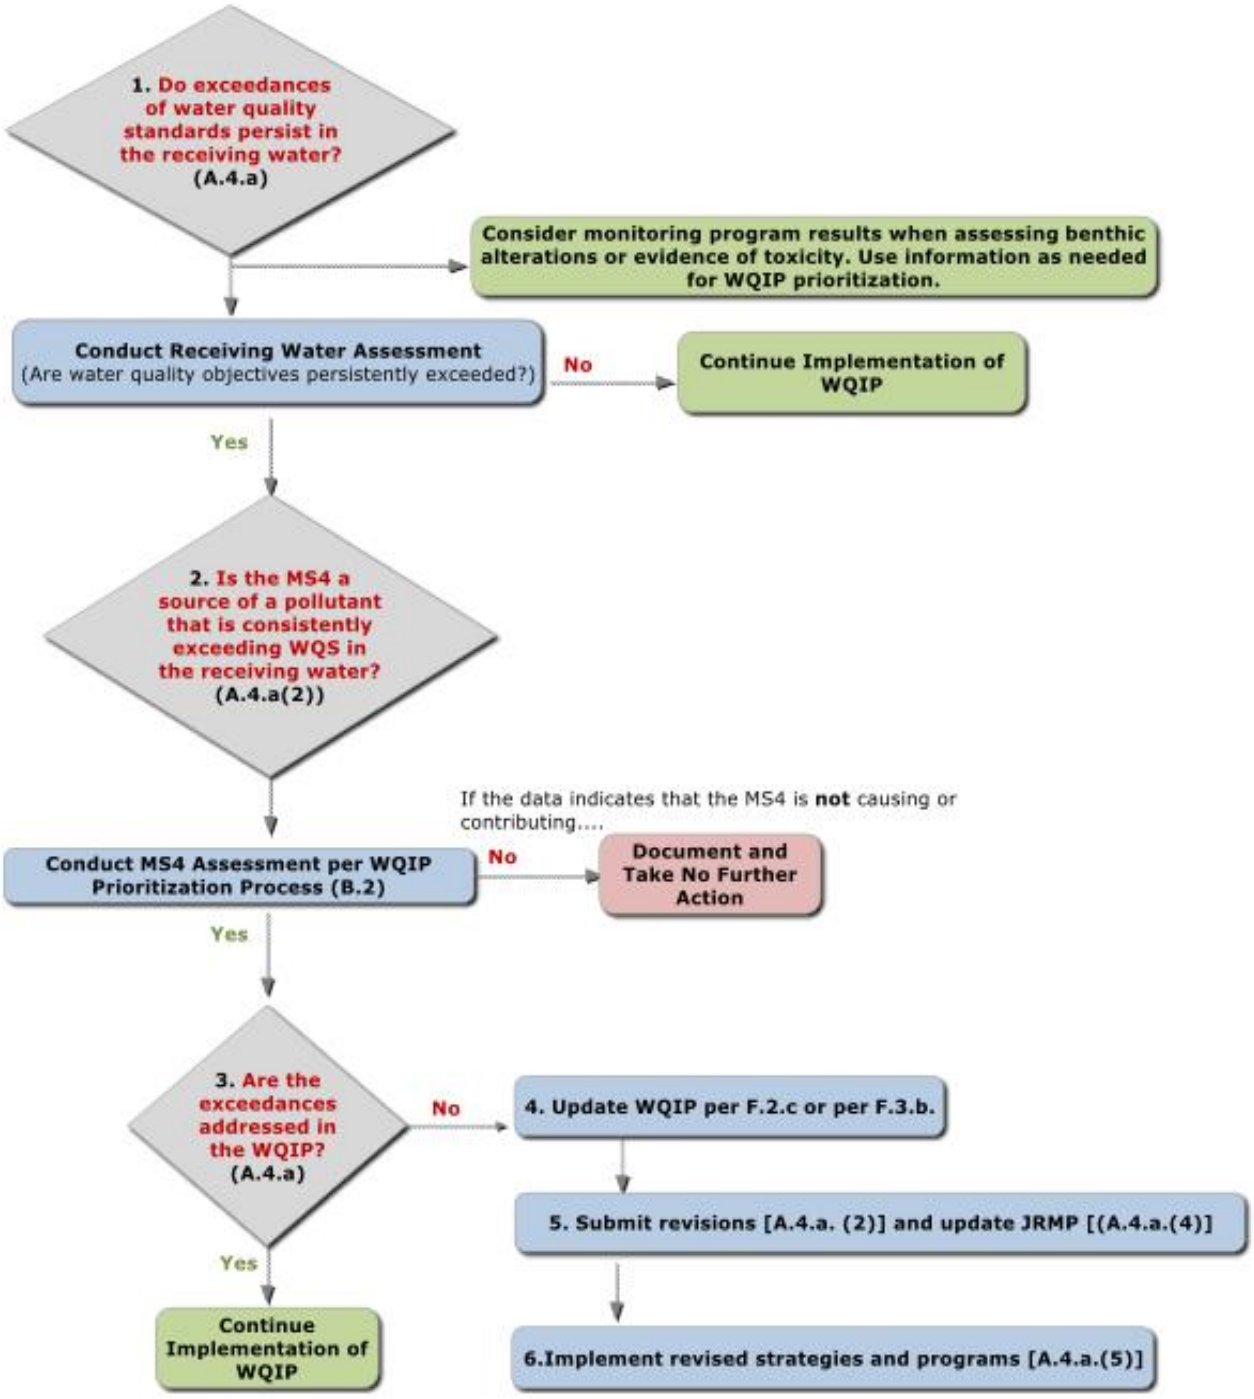

Figure 6-2. Receiving Waters Water Quality Standards Exceedance Process

6.5 WATER QUALITY IMPROVEMENT PLAN UPDATES AND REPORTING

Updates to the WQIP will include a public participation process as required by Provision F of the Permit. Annual updates will likely include a more abbreviated public process unless substantial modifications are identified. A full public process will be implemented as part of updates associated with the Report of Waste Discharge. Updates will include a process to obtain data from the public, participation by the Consultation Committee, and submittal for approval. As applicable, updates to the WQIP will be initiated within six months following OAL and USEPA approval of any TMDLs with Waste Load Allocations (WLAs) assigned to the Copermittees. Updates will be deemed appropriate for inclusion in the WQIP 90 days following submission to the Regional Water Board unless otherwise directed by the Regional Water Board Executive Officer. Updates to the WQIP will also be made available to the public via two Regional Clearinghouses (i.e., RCFCWCD and Project Clean Water websites) following acceptance by the Regional Water Board. **Table 6-6** provides a tentative timeline for WQIP implementation and the adaptive management process.

Table 6-6. Water Quality Improvement Plan Implementation and Adaptive Management Process, as required by Order No. R9-2013-0001, as amended by Order Nos. R9-2015-0001 and R9-2015-0100

Milestone	Target Date	Adaptive Management Triggered
Report of Waste Discharge	December 2017	
WQIP Submittal	January 2018	
Anticipated WQIP Acceptance	Spring 2018	
WQIP Implementation	90 Days following Acceptance by Regional Water Board	
Annual Reporting	January (2019)	Strategies and schedules
Anticipated Permit Adoption	February 2019	
Effective date for Permit	50 days after Adoption	
Annual Reporting	January of each year (2020, 2021, 2022, 2023)	Strategies and schedules
Report of Waste Discharge	180 days prior to Permit Expiration	• Priority water quality conditions • Goals and schedules • Monitoring and assessment program

7 Glossary of Terms

Agencies – Copermittees and the City of Menifee

Controllable – (or "within agency control") consistent with the scope of the Permit, conditions that are within the regulatory authority of the agency and can feasibly be addressed or treated at the point of entry, within, or at the MS4 outlets are controllable. This requires the availability of feasible options for treating the condition. (See accepted San Luis Rey WMA WQIP, Section 2.3.1)

Co-Permittee – A permittee to a NPDES permit that is only responsible for permit conditions related to the discharge for which it is operator [40 CFR 122.26(b)(1)]. For the purposes of the MS4 Permit, a Copermittee is one of the individual permittees identified in Tables 1a – 1c of the Permit. (See Permit Attachment C)

Dry Season – May 1 to September 30. (See Permit Attachment C)

Dry Weather – Weather is considered dry if the preceding 72 hours has been without measurable precipitation (>0.1 inch). (See Permit Attachment C)

Existing Development – Any area that has been developed and exists for municipal, commercial, industrial, or residential purposes, uses, or activities. May include areas that are not actively used for its originally developed purpose, but may be re-purposed or redeveloped for another use or activity. (See Permit Attachment C)

Municipal Separate Storm Sewer System (MS4) – A conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains): (i) Owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or designated and approved management agency under section 208 of the CWA that discharges to waters of the United States; (ii) Designated or used for collecting or conveying storm water; (iii) Which is not a combined sewer; (iv) Which is not part of the Publicly Owned Treatment Works (POTW) as defined at 40 CFR 122.26. (See Permit Attachment C)

Open Space – Undeveloped areas of the watershed that are do not contain areas of existing development (e.g., commercial, residential, industrial, municipal facilities) and are not under construction. (See Permit Fact Sheet, Provision E.5)

Storm Drain – [need new definition]

Wet Season (aka Rainy or Storm Season) – October 1 to April 30. (See Permit Attachment C)

Wet Weather – Weather is considered wet up to 72 hours after a storm event of 0.1 inches and greater, unless otherwise defined by another regulatory mechanism (e.g., a TMDL). (See Permit Attachment C)

Appendix 1 – Comments and Responses

COMPLIANCE CHECKLIST COMMENTS FROM THE WQIP JANUARY 4, 2018 SUBMITTAL AND COPERMITTEE RESPONSES 10-9-18

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS

PROVISION B.2.A: ASSESSMENT OF RECEIVING WATER CONDITIONS

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS
PROVISION B.2.a: ASSESSMENT OF RECEIVING WATER CONDITIONS

Provision	Requirement	Y/N	Location in Plan	Comments	Co-Permittee Response
B.2.a.(3)	Sensitive or highly valued receiving waters (e.g. CWA 320 estuaries, MPAs, wetlands, BIOL BU RWs, ASBS)?	N	Chapter 3	Diamond Lake, Vail Lake, and Skinner Lake are not clearly identified as drinking water reservoirs that depend on the runoff from the watershed. Both the MWD and water agencies identify urban runoff as an ongoing issue for nutrients and the ability to treat water to meet drinking water standards. This information must be included in the WQIP and strategies must be identified that address water agency concerns.	New Section 1.4 was added with additional description of the lakes. The section includes description of the operation of the lakes as drinking water supplies and identifies all their beneficial uses. The lakes have no 303(d) listings. The strategies identified in Section 4 will be implemented in the Upper SMR Subwatershed as applicable per the JRMPs for the Counties of Riverside and San Diego to addres any pollutants from developed areas.
B.2	The Copermittees must identify the water quality priorities within each Watershed Management Area that will be addressed by the Water Quality Improvement Plan. Where appropriate, Watershed Management Areas may be separated into subwatersheds to focus water quality prioritization and jurisdictional runoff management program implementation efforts by receiving water.	Y	Chapter 3	Copermittees assigned a single HPWQC to the entire WMA and developed strategies, schedules and numeric goals for the Upper and Lower Santa Margarita River subwatersheds. However, the “upper watershed” does not extend to the entire watershed and excludes areas east of the three drinking water reservoirs. These drinking water reservoirs are included as part of the Basin Plan and are considered waters of the United States. It is inappropriate to exclude this portion of the watershed based on the rationale that these reservoirs “act as a sump.” Discharges occur from these facilities to the lower portion of the WMA. The WQIP must be revised to graphically show that this area is part of the HPWQC. In addition, there are no MS4 facilities located in this part of the WMA. The WQIP must use the CWA definition of MS4 in attachment C. As currently written throughout the WQIP, the term “storm drain” is intended in many locations to refer to the narrow definition of this term and not the regulatory definition set forth in the Regional MS4 Permit, Attachment C The Copermittees must clearly identify the extent of the MS4 conveyance system as defined in Attachment C, inclusive of creek systems used to convey urban runoff flow. It is unclear if the land use tables exclude in section 3 exclude the east WMA area or not (ie Table 3-1).	Note that two HPWQCs were assigned: eutrophication impacts (dry weather); and nutrient loading to waterbodies (dry and wet weather). The WQIP has been revised to divide the SMR WMA into three subwatersheds, the Upper, Middle, and Lower. Two new maps were added to help describe the Upper SMR Subwatershed which show existing drainage and transportation infrastructure. All of the WQIP maps, tables, and text were revised for consistency. New Section 1.4 includes description of the operation of the lakes as drinking water supplies and identifies all their beneficial uses. The Upper SMR Subwatershed was evaluated with the same methodology as the Middle and Lower Subwatersheds. However, their were insufficient recent data on receiving water conditions and virtually no data regarding MS4 discharges in the Upper SMR Subwatershed. Therefore, HPWQCs were not assigned to the subwatershed. The Upper SMR Subwatershed will be further evaluated as new data become available. A new monitoring site will be established on one of the main tributaries to Vail Lake to provide such data. The Upper SMR Subwatershed includes the three subject lakes. Discharges from the lakes to the Middle SMR Subwatershed only occur in very rare circumstances. Additional research was conducted to verify how the lakes are operated with regard to filling of the lakes and releases from the lakes to downstream areas. Diamond Valley Lake is filled predominantly by imported water via aqueducts, and would release from the dam to downstream waters only in emergencies. Skinner is also filled predominantly from imported flows but does receive significant inflows from the contributing watershed area in wet years. It releases flows to downstream drainages onky in emergencies. Vail Lake receives most inflows from the large upstream drainage area during storms, but rarely releases flows over the spillway. Stored water from the lake is routed to a system of downstream spreading basins and does not feed downstream channels. Instead, the Rancho California Water District releases imported water directly into Murrieta Creek near the SMR gorge to fulfil downstream flow requirements. The term “storm drain” is now used in the text only where appropriate. The terms “MS4,” “storm drain,” and “storm drain system” are not synonomous and the text has been revised accordingly throughout

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS

PROVISION B.2.a: ASSESSMENT OF RECEIVING WATER CONDITIONS

Provision	Requirement	Y/N	Location in Plan	Comments	Co-Permittee Response
					the WQIP. Every effort was made to ensure that the WQIP is consistent with the definitions in the Regional MS4 Permit. Table 3-1 has been verified so that it is correct for the entire WMA.
B.2.a.(1)	Receiving waters on 303(d) List?	Y	Chapter 3	The Plan is inconsistent and has conflicting statements as to which 303(d) list is used for the development of the Plan. Both the EPA 2010 approved list and the 2016 San Diego Water Board list are referenced as the basis for Plan development (ie Plan text and Appendices). Data has been submitted in support of the 2016 303(d) listings and is required to be considered in the Plan development.	See 2.3.1.1: the Step 1B assessment includes a review of the data used for the 2010 list, and the data used for the development of the 2014/2016 list to identify additional constituents that may be contributing to impairments based on data collected since the 2010 303(d) list. Every effort was made to ensure the related text is consistent.
B.2.a.(2)	TMDLs adopted and in development?	Y	Chapter 3	The Plan includes and considers the Rainbow Creek TMDL. And the Santa Margarita River Estuary initiative.	N/A
B.2.a.(5)	Known historical vs. current physical, chemical, and biological water quality conditions?	Y	Chapter 3	• Include the results of the PPPC Study in the Data set assessment • Include recent results of the bacteria Cost Benefit Analysis /HF 183 Study • Include Locations of steelhead trout preserve studies in the WMA. Identify strategies that affect this protected population.	These studies were evaluated as part of the data review. The Steelhead Trout rehabilitation efforts are occurring within the Santa Margarita Ecologiocal Reserve. This area is identified on the Critical Coarse Sediment Yield Map (WMAA: Attachment G). Development projects that propose to discharge to the Reserve area are required to conduct an analysis and mitigate any potential impacts to coarse sediment supply.
B.2.a.(7)	Available evidence of erosional (i.e. hydromodification) impacts?	Y	Table 2-12	Copermittees included areas of concern by Consultation Panel members and known areas of hydromodification in the WMA.	N/A
B.2.a	Did the Copermittees consider the following to identify priorities? The Copermittees must consider the following, at a minimum, to identify water quality priorities based on impacts of MS4 discharges on receiving water beneficial uses:	Y	Chapter 3		
B.2.a.(4)	Receiving water limitations of Provision A.2?	Y	Chapter 3		
B.2.a.(6)	Available, relevant, and appropriately collected and analyzed RW monitoring data?	Y	Section 2.2		
B.2.a.(8)	Available evidence of adverse chemical, physical, and biological integrity impacts?	Y	Section 2.2		
B.2.a.(9)	Potential improvements to overall condition of WMA that can be achieved?	Y	Section 2.6		

PROVISION B.2.B: ASSESSMENT OF IMPACTS FROM MS4 DISCHARGES

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS **PROVISION B.2.b: ASSESSMENT OF IMPACTS FROM MS4 DISCHARGES**					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.b	Did the Copermittees consider the following to identify potential impacts to RWs from MS4 discharges:	Y	General Comment	RCFCWD activities are still not included in applicable assessment categories for some of the provisions despite several discussions with RCFCWD that potential pollutant generating activities and areas conducted by RCFCWD were not exempt from the assessment. There is no discussion of activities or areas that RCFWCD has authority or control over under some of the assessment categories (i.e. Municipal.	Regarding the HPWQC, nitrogen and phosphorus loads for the RCFCWCD were not calculated or included in the SMRNIG model. However, RCFCWCD facilities were considered in the assessment (e.g., Table 3-3 and Figure 3-3). The RCFCWCD understands that the strategies identified in Table 4-11 are designed to address impacts from its facilities and activities.
B.2.b.(2)	Available, relevant, and appropriately collected and analyzed MS4 outfall storm water and non-storm water monitoring data?	Y	Section 2.7	It is not clear how the "*...connectivity from the outfalls to the receiving waters*…" in dry weather conditions limits the geographic extent of the HPWQC based on algal biomass. It is unclear what is meant by "dry weather." This seems contradictory to the results of the estuary modeling and other discussions in the Plan. The geographic extent described for the HPWQC for the Upper Santa Margarita is inconsistent throughout the Plan text, tables, and appendices. The Plan appendices have a longer list of the geographic extent for the HPWQC which are more in accordance with the Basin Plan intent (i.e. beneficial uses and supporting WQOs are year-round). The WQIP must include the area east of the reservoirs as part of the geographic extent given these part of the WMA is urbanized and conveys pollutants directly to the reservoirs via creek systems which are considered part of the MS4 system.	Note that we do not find the referenced text regarding "connectivity" in the submitted WQIP; and the WQIP does not include a Section 2.7. The hydrologic connectivity between the Upper and Middle SMR Subwatersheds is described in new Section 1.4 (as in responses above). Dry weather is defined in the WQIP in several places (Section 4.1.1; Table 5-1) as "where there is less than 0.1 inch of rainfall within the previous 72 hours" consistent with the Regional MS4 Permit. The Upper SMR Subwatershed was evaluated with the same methodology as the Middle and Lower Subwatersheds. However, their were insufficient recent data on receiving water conditions and virtually no data regarding MS4 discharges in the Upper SMR Subwtareshed. Therefore, HPWQCs were not assigned to the subwatershed. The Upper SMR Subwatershed will be further evaluated as new data become available. Every effort was made to ensure the WQIP (text, tables, figures) is internally consistent and consistent with the Regional MS4 Permit. The strategies identified in Section 4 will be implemented in the Upper SMR Subwatershed as applicable per the JRMPs for the Counties of Riverside and San Diego to address any pollutants from the developed areas.

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS **PROVISION B.2.b: ASSESSMENT OF IMPACTS FROM MS4 DISCHARGES**					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.b.(3)	Locations of each Copermittee's MS4 outfalls?	Y	Section 2.6	See comment to B.2.b (2)	See response to Comment to B.2.b(2), above.
B.2.b.(4)	Locations of MS4 outfalls with persistent non-storm water discharges that cause and contribute?	Y	Section 2.6	See comment to B.2.b (2)	See response to Comment to B.2.b(2), above.
B.2.b.(5)	Locations of MS4 outfalls known to discharge pollutants in storm water that cause and contribute?	Y	Section 2.9	See comment to B.2.b (2)	See response to Comment to B.2.b(2), above.
B.2.b.(1)	Prohibitions of Provision A.1 and Effluent Limitations of Provision A.3?	Y	Section 2.6, 2.7		
B.2.b.(6)	Potential improvements to quality of MS4 discharges that can be achieved?	Y	Section 2.10		

PROVISION B.2.C: IDENTIFICATION OF PRIORITY WATER QUALITY CONDITIONS

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS **PROVISION B.2.C: IDENTIFICATION OF PRIORITY WATER QUALITY CONDITIONS**					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.c.(1)(b)	Geographic extent of condition in WMA, or indicate not known?	Y	Sections 2.6, 2.7, 2.8	It is still unclear how the Copermittees determined the geographic extent of the conditions in the WMA. It appears that the WMA is still excluded non-perenniel stream systems in the development of the geographical extent for the HPWQC in the WMA on the basis that MS4 outfalls discharging to dry receiving waters would not result in impacts. This is inconsistent with the San Diego Water Board Basin Plan which designates beneficial uses in receiving waters year round. The geographic extent described is also inconsistent with the Santa Margarita Estuary technical reports and identified nutrient load sources. It is also inconsistent with footnotes and the geographical extent described in the plan text, tables, and technical appendices. In addition, it appears that the Copermittees are excluding receiving waters in developed areas from the MS4 system.	Non-perennial stream systems are included in the analysis as noted in Section 1.5.2.5.1: "Perennial/non-perennial criteria were removed from the revised prioritization process and the assessments no longer exclude areas based on flow." The WQIP has been revised to divide the SMR WMA into three subwatersheds, the Upper, Middle, and Lower. Two new maps were added to help describe the Upper SMR Subwatershed which show existing drainage and transportation infrastructure. All of the WQIP maps were revised for consistency. Text and tables have been revised accordingly Every effort was made to ensure that the WQIP (text, table, figures) is consistent with the definitions in the Regional MS4 Permit.
B.2.c.(2)	Did the Copermittees identify the highest priority water quality conditions to be addressed?	Y	Sections 2.8,2.9	The Copermittees selected a HPWQC for Upper and Lower Santa Margarita River. The "upper" WMA does not include any part of the WMA above the reservoirs (Diamond, Vail, Skinner). It is unclear how the HPWQCs are addressed in this area or how the Tables are consistent throughout the WQIP.	The WQIP has been revised to divide the SMR WMA into three subwatersheds, the Upper, Middle, and Lower. All of the WQIP maps, text, and tables were revised for consistency. The Upper SMR Subwatershed was evaluated with the same methodology as the Middle and Lower Subwatersheds. However, their were insufficient recent data on receiving water conditions and virtually no data regarding MS4 discharges in the Upper SMR Subwtareshed. Therefore, HPWQCs were not assigned to the subwatershed. The Upper SMR Subwatershed will be further evaluated as new data become available. The strategies identified in Section 4 will be implemented in the Upper SMR Subwatershed as applicable per the JRMPs for the Counties of Riverside and San Diego to minimize any adverse impacts pollutants from developed areas

B.2.c.(1)(c)	Temporal extent of condition (e.g. dry and/or wet weather)?	Y	Sections 2.7, 2.8	Copermittees selected both wet and dry PWQCs and HPWQCs for the WMA (Eutrophication for WMA (Dry) and Rainbow Creek TN and TP TMDL (Wet and Dry))	N/A
B.2.c.(2)	Did the Copermittees provide a rationale for selecting a subset of the conditions identified in B.2.c.(1)?	Y	Sections 2.8, 2.9	Copermittees selected a HPWQC for Upper and Lower Santa Margarita River. See previous comment.	N/A
B.2.c.(1)(d)	The Copermittees with MS4 discharges that may cause or contribute to condition?	Y	Section 2.9		
B.2.c.(1)(e)	An assessment of the adequacy of and data gaps in monitoring data?	Y	Section 2.9		
B.2.c.(1)	Did the Copermittees use information from Provisions B.2.a and B.2.b to develop a list of priority water quality conditions?	Y	Sections 2.5, 2.6		
B.2.c.(1)	Did the Copermittees' priority water quality condition in the list include:		N/A		
B.2.c.(1)(a)	Beneficial use associated with condition?	Y	Section 2.5		

PROVISION B.2.D: IDENTIFICATION OF MS4 POLLUTANT SOURCES AND/OR STRESSORS

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS **PROVISION B.2.d: IDENTIFICATION OF MS4 POLLUTANT SOURCES AND/OR STRESSORS**					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.d.(3)(a)	Other MS4 outfalls (e.g. Phase II and Caltrans)?	Y	Section 2.6	It is still unclear in the Plan how other MS4 outfalls (ie Caltrans, Phase II facilities) are addressed, identified, or considered to adequately meet this provision. This still appears to be missing from the assessment. Clarify where this is included in the Plan.	These discharges and related regulations are described in Section 3.4.1. Note that Caltrans and Camp Pendleton are stakeholders in the SMRNIG.
B.2.d.(3)(b)	Other NPDES permitted discharges?	Y	Sections 2.6, 2.9	Agricultural lands within Copermittee's land use authority are under their control. Statements are still inconsistent in the WQIP. It is unclear what land uses in the WQIP and how these are defined as not under the Copermittee's authority. Identify in the Plan what land use authority the Copermittees do have over agricultural land uses or operations. Provide a clearer discussion of what types of agricultural land uses in the WMA fall under the San Diego Water Board Agricultural Orders and which do not.	We do not find any inconsistencies regarding Copermittee land use authority in Section 2.6. Section 3.2.4.2 defines commercial agriculture operations and describes the agriculture regulatory approach, which includes enrollment in the Regional Water Board's Ag WDRs, and actions by Copermitees—including authority under their ordinances.
B.2.d.(1)(e)	Areas not within the Copermittees' jurisdiction (Phase II, tribal, state, federal)?	Y	Sections 2.8, 2.9	The Plan is still vague and unclear in describing these areas. Clearly identify and define areas not in Copermittee jurisdiction. Ie undeveloped lands are not clearly described. The Plan still does not clearly define terms used through out the text, tables, and appendices (ie non- MS4, controllable, uncontrollable, storm drain). The Plan must be clear what is meant by these terms and provide a clear discussion how these terms link or relate to the Rainbow Creek TMDL and the terms being used for the development of the Santa Margarita River Estuary.	New Section 1.4 describes areas outside Copermittee jurisdiction in the Upper SMR Subwatershed and includes a map. The term "storm drain" is now used in the text only where appropriate. The terms "MS4," "storm drain," and "storm drain system" are not synonomous and the text has been revised accordingly throughout the WQIP. Every effort was made to ensure that the WQIP is consistent with the definitions in the Regional MS4 Permit.
B.2.d.(3)(d)	Other non-point sources (e.g. ag, wildlife/natural)?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	Copermittees provided summary of studies for natural background sources in WMA.	
B.2.d.(4)(a)	Findings from Copermittees' ICID programs?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	Copermittees expanded discussion of ICID program	
B.2.d.(4)(b)	Findings from Copermittees' Outfall monitoring?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	See prior comments on basis for geographic extent	
B.2.d.(4)(c)	Findings from Copermittees' RW monitoring?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	See prior comments on basis for geographic extent	
B.2.d.(4)(d)	Findings from MS4 outfall and RW assessments?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	See prior comments on basis for geographic extent	
B.2.d.(4)(e)	Other available, relevant, and appropriately collected data, information, or studies?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	Include studies identified in prior comments	

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS PROVISION B.2.d: IDENTIFICATION OF MS4 POLLUTANT SOURCES AND/OR STRESSORS					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.d.(5)	Adequacy of available data to identify and prioritize sources and/or stressors?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10	Include studies identified in prior comments. Plan stressors excludes sources to the MS4 identified in SMR Estuary technical reports (agriculture) which are the majority of the load. Statements are still inconsistent with these findings throughout the WQIP.	The referenced studies have been included. Agricultural sources have been considered as described in 3.3.3.1 (Special study); 3.3.3.3 (Stuart Mesa Ag fields); 3.3.4 (SMRNIG Model findings show Ag as the largest source of N and P loads); and Table 4.1.2 shows percentage of N and P loads for San Diego County.
B.2.d	Did the Copermittees identify and prioritize known and suspected sources of storm water and non-storm water pollutants and/or other stressors that cause or contribute to the high priority conditions?	Y	Sections 2.8, 2.9		
B.2.d	Did the Copermittees consider:	Y	Sections 2.8, 2.9		
B.2.d.(1)(a) The	Each Copermittee's inventory or construction sites, industrial facilities, and areas of existing development?	Y	Sections 2.8, 2.9		
B.2.d.(1)(b)	Publicly owned parks and/or recreational areas?	Y	Sections 2.8, 2.9		
B.2.d.(1)(c)	Open space areas?	Y	Sections 2.8, 2.9		
B.2.d.(1)(d)	All currently operating or closed municipal landfills or other facilities for municipal waste?	Y	Sections 2.8, 2.9		
B.2.d.(2)(a)	Locations of Copermittees' MS4 outfall that discharge to receiving waters?	Y	Section 2.6		
B.2.d.(2)(b)	Locations of major structural controls (e.g. retention basins, detention basins, infiltration devices, etc.)?	Y	Section 2.9		
B.2.d.(3)(c)	Other point sources (e.g. private outfalls)?	Y	Sections 2.6, 2.7,2.8,2.9 and 2.10		

Provision B.2.E: Identification of Potential Water Quality Improvement Strategies

PROVISION B.2: PRIORITY WATER QUALITY CONDITIONS PROVISION B.2.e: IDENTIFICATION OF POTENTIAL WATER QUALITY IMPROVEMENT STRATEGIES					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Comments**	**Co-Permittee Response**
B.2.e	Did the Copermittees identify potential strategies based on findings from Provisions B.2.a-d to address highest priority conditions from Provision B.2.c, or MS4 pollutant sources or stressors from Provision B.2.d?	Y	Section 3.0 General Comment	Provision E.5 is not adequately addressed in the strategies. The WQIP should identify strategies to address protected Steelhead populations and drinking reservoirs.	Steelhead rehabilitation area in the SMR Ecological Reserve-the main stressor, sediment supply, is addressed by WQMP requirements for Critical Coarse Sediment Yield. MUN beneficial uses in the lakes in the Upper SMR Subwatershed are not impaired as described in new Section 1.4, and WQIP Strategy implementation as applicable through the JRMPs will address pollutants from developed areas.
B.2.e.(3)	Stream, channel, and/or habitat rehabilitation projects?	Y	Section 3	Copermittees identified a net pollution load reduction would be achieved	N/A
B.2.e	Do potential strategies to address highest priority conditions from Provision B.2.c, or MS4 pollutant sources or stressors from Provision B.2.d include:	Y	Section 3.0		
B.2.e.(1)	Structural BMPs, non-structural BMPs, incentives, or programs that can potentially be implemented?	Y	Section 3.0		
B.2.e.(2)	Retrofitting projects in areas of existing development?	Y	Section 3.0		

PROVISION B.3: WATER QUALITY IMPROVEMENT GOALS, STRATEGIES AND SCHEDULES

Provision B.3.A: Water Quality Improvement Goals and Schedules

PROVISION B.3: WATER QUALITY IMPROVEMENT GOALS, STRATEGIES AND SCHEDULES PROVISION B.3.a: WATER QUALITY IMPROVEMENT GOALS AND SCHEDULES					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Notes**	**Co-Permittee Response**
Numeric Goals					
B.3.a.(1)(a)	**Final numeric goals** capable of demonstrating: (i) MS4 discharges will not cause or contribute to exceedances in RWs; AND/OR (ii) Conditions in RWs and associated habitat are protected from MS4 discharges; AND/OR (iii) Beneficial uses of RWs are protected from MS4 discharges and will be supported.	Y	Section 3.1,3.2	Final Numeric Goals are identified for Rainbow Creek TMDL and HPWQC for Upper and Lower Santa Margarita River. Pathway descriptions are unclear what non-stormwater flows are under Copermittee control. NSWDs to the MS4 are prohibited. It is unclear what the basis for the metric for assessment of flow or what the metric is. The WQIP compliance pathway for the Rainbow Creek TMDL includes a compliance analysis in Appendix 3B. The San Diego Water Board is not in agreement with the tiered compliance approach in the analysis. Tier 1 excludes agricultural operations in the analysis in Appendix 3B. This is inconsistent with Attachment E of the Regional MS4 Permit,	Section 4.2.2.1 has been revised, which outlines structural BMP strategies for the Rainbow Creek TMDL area, and additional clarification has been provided at 4.2.2.2.4.3; the **Rainbow Creek Nutrient Reduction and Management Plan**—as discussed between Regional Board and staff from the County of San Diego in September and October 2018.
B.3.a.(1)(b)(i)	One or more interim numeric goals to demonstrate progress toward achieving each final numeric goal	Y	Section 3.1,3.2	See prior comment. It is unclear if the final numeric goal is the interim numeric goal for the Rainbow Creek TMDL. The HPWQC has interim numeric goals.	See Rainbow Creek TMDL response above.
B.3.a.(1)(b)(ii)	At least one interim numeric goal expressed as a reasonable increment of final numeric goal	Y	Section 3.1,3.2	See prior comments.	See above response.
B.3.a.(1)(b)(iii)	At least one interim numeric goal for each 5 year period between acceptance of Plan and achievement of each final numeric goal	Y	Section 3.1	See prior comments. It is unclear for the Rainbow Creek TMDL if the final numeric goal is the interim numeric goal for the 5 year period.	See above response.
Schedules for Final and Interim Numeric Goals					
B.3.a.(2)(a)	**Dates for achieving all final numeric goals** based on:		N/A	Provide the City of Menifee interim and final numeric goals. The City has "TBD" in the Plan.	Goals and schedules applicable to the Ciy of Menifee are included in Table 4-2.
B.3.a.(2)(a)(i)	Final compliance dates of applicable TMDLs	Y	Section 3.1,3.2	Based on draft schedule proposed for SMR Estuary and Rainbow Creek Adopted TMDL in Att. E.	N/A
B.3.a.(2)(a)(iii)	Achievement of final numeric goals must be as soon as possible	Y	Section 3.1,3.2	Based on draft schedule proposed for SMR Estuary and Rainbow Creek Adopted TMDL in Att. E.	N/A

RIVERSIDE COUNTY FLOOD CONTROL AND WATER CONSEVATION DISTRICT

PROVISION B.3: WATER QUALITY IMPROVEMENT GOALS, STRATEGIES AND SCHEDULES

PROVISION B.3.b: WATER QUALITY IMPROVEMENT STRATEGIES AND SCHEDULES

Provision	Requirement	Y/N	Location in Plan	Notes	Co-Permittee Response
RIVERSIDE COUNTY FLOOD CONTROL AND WATER CONSERVATION DISTRICT					
Jurisdictional Strategies					
B.3.b.(1)(a)	Did **each** Copermittee identify **Jurisdictional Strategies** to be implemented under Provisions E.2 through E.7, including descriptions of the following:	N	Section 3.2, Appendix 3A	Table 4-5 Footnote 3. Based on land area and potential sources of nutrients, for the purposes of the Water Quality Improvement Plan development, RCFCWCD is considered to be a less than significant contributor to nitrogen and phosphorus loading. If determined necessary by the SMRNIG, loading estimates may be developed in the future, at which time, they will be included within the Water Quality Improvement Plan through the adaptive management process. This footnote must be revised or confirmed with the Stakeholder Group – RFCFCD is required to participate in the TMDL. RFCFD must fully implement the strategies. The WQIP does not provide adequate explanation of activities and land uses that may contribute to dry weather loading of nutrients for this footnote to be in the WQIP.	Footnote revised. The RCFCWCD facilities were evaluated, but the District was not assigned loads in the SMRNIG Model. The District will implement the strategies to address the PWQCs and HPWQCs.
B.3.b.(1)(a)(iii)	Education programs that will be implemented, as applicable for those areas or sources	Y	Section 3.2, Appendix 3A	Outreach to HOAs, yard waste reduction, river clean up.

. OPTIONAL WMAA

PROVISION B.3: WATER QUALITY IMPROVEMENT GOALS, STRATEGIES AND SCHEDULES PROVISION B.3.b: WATER QUALITY IMPROVEMENT STRATEGIES AND SCHEDULES					
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Notes**	**Co-Permittee Response**
Optional Watershed Management Area Analysis					
B.3.b.(4)(a)(i)	A description of dominant hydrological processes	N	Section 4.3, Appendix 4B	Does not assess impacts to the Santa Margarita River Estuary from proposed exemption and any impacts to the success of achieving the water quality objectives in the estuary.	New evaluation and rationale were provided in the WMAA, Section 4.3.3. The proposed hydromodification exemption for the SM River is not expected to adversely impact the Estuary.
B.3.b.(4)(c)	If the Copermittees performed a WMAA, did the Copermittees identify areas within the WMA where it is appropriate to allow PDPs to be exempt from hydromodification BMP requirements with supporting rationale?	N	Section 3.3, Appendix 4B	Copermittees received comments from San Diego Water Board during the WQMP review on the WMAA. WMAA was not revised when submitted as part of the complete WQIP. Copermittees have actively worked to address the WMAA comments with the San Diego Water Baord since the time of the January 2018 WQIP submittal. Comments submitted to the CoPs on the WMAA previously remain unaddressed. See attached WQMP commetns dated March 16, 2018 and 5/8/18.	All WMAA comments have been addressed as outlined below.
B.3.b.(4)(a)	Did the Copermittees perform a Watershed Management Area (WMAA) analysis?	Y	Section 4.3, Appendix 4B	WMAA is not completed for a single watershed. Must be unified for SMR watershed. Currently separated into upper and lower SMR analyses separately performed by San Diego County and Riverside County Copermittees. A unifed study is required in order to be compliant with provision B.3.b.(4)(a).	The data source tables for San Diego and Riverside Counties were combined and a more comprehensive analysis was conducted for the entire WMA.
B.3.b.(4)(a)(ii)	A description of existing streams in the watershed, including bed material and composition, and if perennial or ephemeral	Y	Section 4.3, Appendix 4B	WMAA is not completed for a single watershed. Must be unified for SMR watershed. Currently separated into upper and lower SMR analyses separately performed by San Diego County and Riverside County Copermittees. A unifed study is required in order to be compliant with provision B.3.b.(4)(a).	The data source tables for San Diego and Riverside Counties were combined and a more comprehensive analysis was conducted for the entire WMA.
B.3.b.(4)(a)(iii)	Current and anticipated land uses	Y	Section 4.3, Appendix 4B	See previous comment. Not a unified analysis.	
B.3.b.(4)(a)(iv)	Potential coarse sediment yield areas	Y	Section 4.3, Appendix 4B	See previous comment. Not a unified analysis.	
B.3.b.(4)(a)(v)	Locations of existing flood control and channel structures	Y	Section 4.3, Appendix 4B	See previous comment. Not a unified analysis.	

PROVISION B.3: WATER QUALITY IMPROVEMENT GOALS, STRATEGIES AND SCHEDULES

Provision	**Requirement**	**Y/N**	**Location in Plan**	**Notes**
CITY OF MURRIETA				
B.3.c.(1)(a)(vii)	For each final numeric goal developed pursuant to Provisions B.3.a and B.3.c.(1)(a)(i)-(v), annual milestones* and the dates for their achievement must be included within each of the next five (5) Water Quality Improvement Plan Annual Report reporting periods, or until the final numeric goal is achieved. * Annual milestones must be clearly and directly linked to, or demonstrate progress is being made toward the achievement of the final numeric goal. Annual milestones may consist of strategy implementation phases, interim numeric goals, and other acceptable metrics. Annual milestones may address multiple numeric goals and/or multiple water bodies, as applicable and appropriate.			
B.3.c.(1)(b)	Is there an analysis that meets all the following conditions:			
B.3.c.(1)(b)(i)	The analysis, with clearly stated assumptions included in the analysis, must quantitatively demonstrate that the implementation of the water quality improvement strategies required under B.3.b will achieve the final numeric goals within the schedules developed pursuant to B.3.a and B.3.c.(1)(a)			
B.3.c.(1)(b)(ii)	The development of the analysis must include a public participation process that allowed the public to review and provide comments on the analysis methodology utilized and the assumptions included in the analysis.			
	Public comments and responses must be included as part of the analysis documentation			
B.3.c.(1)(b)(iii)	The analysis may be performed by an individual Copermittee or jointly by two or more Copermittees			
B.3.c.(1)(b)(iv)	The analysis must be updated as part of the iterative approach and adaptive management process required under B.5.a-b

Santa Margarita River HU Watershed Management Area

LEASESPROVISION B.4: WATER QUALITY IMPROVEMENT MONITORING AND ASSESSMENT PROGRAM

PROVISION B.4: WATER QUALITY IMPROVEMENT MONITORING AND ASSESSMENT PROGRAM

Provision	Requirement	Y/N	Location in Plan	Notes	CoPermittee Response
B.4.a	Does the monitoring and assessment program incorporate the monitoring and assessment requirements of Provision D?	N	B.4 SECTION 5; Appendices 5A	**HMP from 2010 permit not clearly identified. Need locations of 2010 and 2010 requirements included in monitoring program in addition to Regional MS4 Permit requirements.**	The hydromodification monitoring sites have been included in a new map (Figure 5-3) and Table 5-4 with lat-long information in Section 5.3.1.3. Added enhanced description of required Hydromodification Monitoring, including requirements of the 2016 SMR HMP and report submittal date which follows from requirements of the 2010 SMR MS4 Permit.
				Monitoring is not representative of WMA (nothing east of lakes). Submittal dates must be specific. San Diego Water Board requested data updates in Annual Report in addition to final report submittal date. See attached comments from Hiram Sirabia, San Diego Water Board. San Diego Water Board is requiring an additional monitoring location east of the lakes. Current proposed location (902USM828) is not representative of the WMA (ie only urban land uses). Long term monitoring station to be selected in in area representative of the rural residential land uses upstream of drinking water reservoirs.	At section 5.3.1: added description of proposed new Receiving Water Monitoring Station to be sited on Wilson Creek or Temecula Creek upstream from Vail Lake. Also revised Figure 5-1 and related tables with a new station accordingly. HMP hydromodification monitoring final report will be submitted October 31, 2019.
				Confirm that no major MS4 outfalls exist in WMA east of drinking water reservoirs. Special studies must be related to the HPWQC.	Confirmed and noted in new Section 1.4--there are no Major Outfalls in the Upper SMR Subwatershed.
				The intercalibration assessment for toxicity does not qualify as a special study for compliance with the Regional MS4 Permit provision D.3. This study should not be referenced for use as a special study per permit term.	Section 5.3.3 (Special Studies) revised to identify the studies specifically required by the Permit Provision D.3 (not the SMC Intercalibration Study), and a category of other special studies.

PROVISION B.4: WATER QUALITY IMPROVEMENT MONITORING AND ASSESSMENT PROGRAM

Provision	Requirement	Y/N	Location in Plan	Notes	CoPermittee Response
B.4.a	If applicable, does the monitoring and assessment program incorporate the specific monitoring and assessment requirements of applicable TMDLs in Attachment E	Y	B.4 SECTION 5; Appendix 4	Rainbow Creek TMDL (Final Compliance for 12/31/21 – N, Total N, and Total P RWLs per Tables 3.1, 3. 2 , 3.3 and 3.4 – Final TMDL Compliance Determination through WQIP requirements in Att. E, 3.b (3) (e) (ii) TMDL Monitoring must be included in WQIP. **Clarify how the structural BMPs can be used to meet the TMDL compliance dates as Table 3-4 in Appendix 4a states as a footnote: *1.The County of San Diego has concerns in that there is no long-term funding source identified to fund structural BMPs and their ongoing operation and maintenance.*** The requirements is to	Rainbow Ceek TMDL Monitoring is described in Section 5.3.1.6, and in Section 5.3.2.4 and has been updated. TMDL Monitoing is also described in Section 4 of WQIP Appendix 5A. Table 3-4 revised to remove the previous Footnote 1.
B.4.a	Did the Copermittees develop and incorporate an integrated monitoring and assessment program into the Water Quality Improvement Plan?	Y	B.4 SECTION 5		
B.4.a	If applicable, does the monitoring and assessment program incorporate the ASBS monitoring requirements in Attachment B to State Water Board Resolution No. 2012-0012?	N/A	N/A	No ASBS monitoring in WMA	

- Provision F.1.a: Water Quality Improvement Plan Development Public Participation Process

PROVISION F.1.A: WATER QUALITY IMPROVEMENT PLAN DEVELOPMENT PUBLIC PARTICIPATION PROCESS				
Provision	**Requirement**	**Y/N**	**Location in Plan**	**Notes**
F.1.a(1)	The Copermittees must implement a public participation process to solicit data, information, and recommendations to be utilized in the development of the Water Quality Improvement Plan. The public participation process must include the following:	Y	N/A	Transparency and communication are two of the four core values of the San Diego Water Board. The Copermittees. The Copermitees addressed the concerns regarding a transparent and adequate public participation process to solicit data, information, and recommendations to be utilized in the development of the Water Quality Improvement Plan.
F.1.a(1)(a)	The Copermittees must develop a publicly available and noticed schedule of the opportunities for the public to participate and provide comments during the development of the Water Quality Improvement Plan. The schedule may be adjusted as necessary by the Copermittees, provided the public is provided timely notification of the changes to the schedule	Y	N/A	The Consultation Panel meetings focused solely on the Plan were noticed via the RCFWCD website for Plan development and participation. Consultation Panel meetings were held after work hours.
F.1.a(1)(b)	The Copermittees must form a Water Quality Improvement Consultation Panel to provide recommendations during the development of the Water Quality Improvement Plan.	Y	N/A	Consultation Panel selected continues to be engaged and continues to be diverse and representative of the WMA stakeholders.
F.1.a(1)(c)	The Copermittees must coordinate the schedules for the public participation process among the Watershed Management Areas to provide the public time and opportunity to participate during the development of the Water Quality Improvement Plans.	Y	N/A	The meetings focused solely on the Plan were scheduled such that the public could participate in the development of other on-going Water Quality Improvement Plans or updates.
F.1.a(2)(a)	The Copermittees must solicit data, information and recommendations from the public to be utilized in the development and identification of the priority water quality conditions and potential water quality improvement strategies for the Watershed Management Area.	Y	NA	The Copermittees included additional data solicited from the public and Consultation Panel members at the request of the San Diego Water Board.
F.1.a(2)(b)	The Copermittees must review the priority water quality conditions the Copermittees plan on including in the Water Quality Improvement Plan with the Water Quality Improvement Consultation Panel to receive recommendations or concurrence	Y	NA	Presented at second Consultation Panel Meeting. Schedule was significantly compressed for Copermittees and CP members to provide meaningful comments.

PROVISION F.1.A: WATER QUALITY IMPROVEMENT PLAN DEVELOPMENT PUBLIC PARTICIPATION PROCESS

Provision	Requirement	Y/N	Location in Plan	Notes
F.1.a(2)(c)	The Copermittees must consider revisions to the priority water quality conditions based on recommendations from the Water Quality Improvement Consultation Panel.	Y	NA	Consultation Panel members input were considered in the selection process of the PWQC and HPWQC.
F.1.a(2)(d)	The Copermittees must include all the potential water quality improvement strategies identified by the public and the Water Quality Improvement Consultation Panel with the submittal of the priority water quality conditions to the San Diego Water Board.	Y	NA	Copermittees included Consultation Panel member and public input on strategies in the selection process of the PWQC and potential water quality improvement strategies developed.
F.1.a(2)(e)	The Copermittees must submit the Water Quality Improvement Plan requirements of Provision B.2 to the San Diego Water Board as early as 6 months and no later than 12 months after the commencement of coverage under this Order.	Y	NA	Received July 7, 2017.
F.1.a(2)(f)	The Copermittees must consider revisions to the priority water quality conditions and potential water quality improvement strategies developed pursuant to Provision B.2 based on public comments received by the close of the comment period.	Y	NA	Copermittees considered Consultation Panel members and public input on strategies in the selection process of the PWQC and potential water quality improvement strategies developed.
F.1.b	Within 24 months after the commencement of coverage under this Order, the Copermittees for each Watershed Management Area must submit a complete Water Quality Improvement Plan in accordance with the requirements of Provision B of this Order to the San Diego Water Board. The San Diego Water Board will issue a public notice and release the Water Quality Improvement Plan for public review and comment for a minimum of 30 days.	Y	NA	Received January 5, 2018 Copermittees considered Consultation Panel members and public input in the development of the complete WQIP.

WMAA Comments and Responses--Additional Responses					
2017 Consultation Committee and Public Comments and Responses - WMAA Comments 12-19-17					
Number	**Name**	**Comment Date**	**Comment**	**January 4, 2018 Response**	**October 9, 2018 Response**
38	Erica Ryan	12/12/2017	Section 4: Figure 4-2 - For the SMR exemption, the Stakeholder Group for the TMDL identified erosion and significant sediment discharge from the watershed (SPAWAR). In addition, erosion has been identified during storm events near the Stuart Mesa fields on Camp Pendleton (San Diego Water Board letter to Camp Pendleton). It does not appear that the cross section assessed is typical of the entire reach to the outfall or that a conclusion can be drawn that there is no issues with this reach or the estuary. Describe why this section is the critical cross section and an adequate location to conclude the river si stable for its entire reach in more detail. Are other cross sections indicative of higher flow velocities downstream?	The District will seek consultant to clarify discussion regarding channel stability. The District will coordinate a meeting with the Regional Board to discuss scope of analysis after the submittal of the WQIP.	An additional field site was evaluated in the lower reach of the SM River on Camp Pendleton Property (see Figure 4-2). The Erosion Potential and Sediment Supply Potential were calculated for the new site. The new analysis in included in Section 4.3.1.
40	Erica Ryan	12/12/2017	Section 4: Explain in more detail the driving factors for the results and statements with regard to the river reach being stable. Merely stating that an x, y z number is less than another number is not transparent and inadequate discussion to support the exemption.	The District will seek consultant to clarify discussion regarding channel stability. The District will coordinate a meeting with the Regional Board to discuss scope of analysis after the submittal of the WQIP.	The explanation of the factors and criteria regarding stability of the SMR Channel has been enhanced in Section 4.3.
59	Erica Ryan	12/12/2017	Attachment C (Now Attachment G): It appears that the medium and high soil loss consist of 90 percent of the potential coarse sediment for the upper WMA. Provide an explanation how this justifies only 9% of the watershed as a CCSY area.	Figure E.1 of Attachment G includes Geologic Groups of the Upper Santa Margarita River Watershed showing the CB, CSI, or CSP geology groups. Based on this analysis it was estimated that 28 percent of the of the SMR study area is a potential coarse sediment yield area and 9 percent of the SMR study area is a potential critical coarse sediment yield area. The majority of the potential critical coarse sediment yield areas were identified to be in the Scrub/Shrub land cover areas with hillslope gradients ranging from 20 to 40 percent.	Staff from the District and WSP Consultants met with Regional Board staff in April 2018 and presented an enhanced analysis of the process to develop the Critical Coarse Sediment Yield Map. The map is now integrated for the entire WMA. A Tech Memo was developed and included in the WMAA Attachments which documents the analysis. Additional "Potential Sediment Source Areas" were added to the CCSY map based on the location of historical sand and gravel deposits in the SMR WMA. In addition, the SMR Ecological Reserve was identified and shown on the CCSY map. The SMRER is the location of ongoing Steelhead Trout habitat restoration efforts. The CCSY Map was included as Attachment G in the updated SMR BMP Manual and requires projects to conduct site-specific analyses and if necessary mitigate any adverse impacts to coarse sediment supply.

1	**SMR WMAA/ General**	The San Diego Water Board has made multiple comments over the last year in prior Consultation Committee meetings, comment letters, and e-mails that a WMAA which is not integrated for the entire Watershed Management Area (WMA) cannot be accepted. The CC draft WMAA repeatedly references a web link to the 2015 San Diego WMAA web link without a substantive description in the WMAA on how the Copermitees used this information for the conclusions described for the WMA. In addition, this referral to a web link does not meet the Regional MS4 Permit intent of public transparency.	A	VSS/JM	Links to the 2015 San Diego WMAA were removed and language applicable to the section, from the 2015 SD WMAA, was added to the SMR WMAA. The 2015 San Diego WMAA was also included as an attachment.
2	**SMR WMAA/ General**	Many of the data sets and maps do not reference a year that the information was based on. This information is important to assess how current data sets are used for the conclusions in the WMAA. For example, a generalized reference to “Copermittee General Plans” is used as a basis for the WMAA. This information and other data sets like this need to be accurately described so that the public can provide meaningful comments. What are the years of adoption? Where are these documents? How were the various land uses reconciled for use in the WMAA? One of the concerns of the San Diego Water Board is that current land use is used for the Plan development so that it is consistent with the TMDL development.	A	VSS/JM	A table with Dataset, Source, year and description, similar to 2015 SD WMAA, was added to Section 2.1.1. The Land Use dataset in the 2015 SD WMAA was also added to the SMR WMAA.
3	**SMR WMAA/ SECTION 1**	There are inaccuracies in this section that need to be corrected: The permit does not exempt projects from implementing TCBMPs if they cannot fully implement the pollutant and HMP controls on -site. The portion that cannot be mitigated on site can be mitigated off site through an Alternative Compliance program.	A	JM	Section 1.1 was modified to clarify.

4	**SMR WMAA/ SECTION 1**	The Water Quality Equivalency has already been accepted in December 2015. See attached. https://www.waterboards.ca.gov/sandiego/water_issues/programs/stormwater/	A	JM	It was noted in the document that Water Quality Equivalency calculations were approved in 2015.
5	**SMR WMAA/ SECTION 1**	HMP exemptions and TCBMPS for water quality and flow control are only applicable to Priority Development Projects.	NA	JM	Thank you for the clarification
6	**SMR WMAA/ SECTION 1**	It is unclear if the information and conclusions in this section are a characterization of the Upper WMA only or of the entire WMA (upper and lower).	A	VSS	Text revised referencing characterization for both the upper and lower SMR watershed.
7	**SMR WMAA/ SECTION 1**	"See web link …for the lower WMA"… is not an adequate description of the data sets and the WMAA is required to be integrated for the ENTIRE WMA.	A	VSS/JM	Links to the 2015 San Diego WMAA were removed and language applicable to the section, from the 2015 SD WMAA, was added to the SMR WMAA. The 2015 San Diego WMAA was also included as an attachment.
8	**SMR WMAA/ SECTION 2**	It would seem logical that information from this section and the technical appendices for the HMP exemption and the 2014 HMP would be a data source for areas susceptible to hydromodification in the Plan (section 2.2). It appears that the CoPs conducted site visits in the WMA for the 2014 HMP Susceptibility Report. This would be especially true of EEM, NEE and NAT facilities listed.	A	JM	The 2014 HMP is included as a data source in section 2.2.1
9	**SMR WMAA/ SECTION 2**	It is unclear how google earth was used in the development of the WMAA.	A	JM	A description was added to the document for the use of google earth.

			Code	**By Whom**	**Response**
10	**SMR WMAA/ SECTION 2**	Intermittent streams are not necessarily ephemeral streams based on the definition used. Provide a description on how locations of ephemeral streams were determined. An ephemeral stream is typically defined as “a stream or portion of a stream which flows briefly in direct response to precipitation in the immediate vicinity and whose channel is at all times above the ground water reservoir.	A	JM	While the specific Regional MS4 Permit language requested classification of perennial or ephemeral, rather than perennial or intermittent, the available data that was referenced in order to classify streams did not include "ephemeral" streams. For reference, the USGS National Hydrography Dataset definition of "ephemeral" is: "contains water only during or after a local rainstorm or heavy snowmelt." None of the stream reaches in the study were classified as ephemeral in the NHD dataset, therefore none are classified as ephemeral in this WMAA.
11	**SMR WMAA/ SECTION 2**	What year are the land uses describing and how were they integrated or modified?	A	JM	Years were added to land use dataset in section 2.3.1
12	**HRU/CCSY**	It is unclear how the conclusion can be made that the majority of the upper WMA does not have CCSY (only 9%???) when the technical appendices map show an indication that trends towards the opposite conclusion. It would be expected that if the majority of the watershed has CB, CSI, or CSP geology, slope, or other factors that it would be more in alignment with the San Diego Portion of the map. In addition, it is unclear how this conclusion was modified by the Copermitees through a review process. Where are the maps of the other contributing factors discussed? (2.4.1)	A	VSS	See Section 2.8 in the SMR WMAA. See Section 3.1.1 - Section 3.1.5 in the Upper SMR Report (WSP 2017). A GLU classified as CB, CSI or CSP were considered as areas that contribute coarse sediment. GLUs rated as CB, CSI or CSP along with a High RUSLE rating were considered as critical coarse sediment yield areas. The result that only 9% of the upper SMR contributes CCSY is attributed to the final RUSLE results. Specifically, the differences along the county border are attributed to the fine resolution of data for the R factor used in the Riverside County portion of the study area, whereas in the San Diego county portion of the study area, only one R data was assigned for each GLU by estimating the area weighted number for the entire study region. For example for the area between 20 and 40 the San Diego study assumed a value of 30. A Memo detailing the differences along the county border is provided in Attachment B of the SMR WMAA.
13	**SMR WMAA/ SECTION 3**	Based on the upper WMA candidate projects it appears that Santa Gertrudis, Bundy Canyon, and French Valley have HMP impacts.	NA	JM	Thank you for the observation.

			Code	**By Whom**	**Response**
14	**SMR WMAA/ SECTION 4**	Provide a more detailed of the change in impervious cover between existing and future development. What years are the data sets? How was this calculated? It would be helpful to provide a summary of the technical information in order to understand the process used and the conclusions.	A	JM	The criteria used to determine the exemptions are appropriate accounts for: (1) hydrology, (2) channel geometry, (3) bed and bank material, and (4) sediment supply. The years of the landuse dataset were added to section 2.3.1. The calculations included in section 4 compare long-term changes in sediment transport capacity, or in-stream work, and sediment supply at specific sections of the creek for the existing and future land use conditions.
15	**SMR WMAA/ SECTION 4**	It is unclear if the sections referred to (ie 2.4) are in the WMAA or the San Diego documents referenced by web links.	A	JM	Links to the 2015 San Diego WMAA were removed and language applicable to the section, from the 2015 SD WMAA, was added to the SMR WMAA. The 2015 San Diego WMAA was also included as an attachment.
16	**SMR WMAA/ SECTION 4**	Explain why the criteria used means that the exemptions are appropriate.	A	JM	The criteria used to determine the exemptions, consistent with the criteria used in the 2015 SD WMAA, are appropriate accounts for: (1) hydrology, (2) channel geometry, (3) bed and bank material, and (4) sediment supply. The selected approach compares long-term changes in sediment transport capacity, or in-stream work, and sediment supply at specific sections of the creek for the existing and future land use conditions.
17	**SMR WMAA/ SECTION 4**	How does the Sp discussion align with the CCSY section? It appears to be contrary to the conclusions and map area in section 2 of the WMAA. Provide a summary explanation as this WMAA should be a standalone document for the entire WMA.	A	JM	Section 4.3.2 refers the reader to Section 4.2.2 which provides an explanation how the Sp analysis was estimated to determine impacts to coarse sediment delivery. The hillslope coarse sediment supply (SYRUSLE) was estimated using the quantitative results. First, the watershed coarse sediment soil loss was estimated for all GLUs producing coarse sediment in the existing condition. Then, the future-condition coarse sediment soil loss was estimated by subtracting the developed parcel soil loss from the existing soil loss. The SMR WMAA includes data and analysis for the entire WMA.

18	**SMR WMAA/ SECTION 4**	Figure 4-2 - For the SMR exemption, the Stakeholder Group for the TMDL identified erosion and significant sediment discharge from the watershed (SPAWAR). In addition, erosion has been identified during storm events near the Stuart Mesa fields on Camp Pendleton (San Diego Water Board letter to Camp Pendleton). It does not appear that the cross section assessed is typical of the entire reach to the outfall or that a conclusion can be drawn that there is no issues with this reach or the estuary. Describe why this section is the critical cross section and an adequate location to conclude the river is stable for its entire reach in more detail. Are other cross sections indicative of higher flow velocities downstream?	C	JM	The District will seek consultant to clarify discussion regarding channel stability. The District will coordinate a meeting with the Regional Board to discuss scope of analysis after the submittal of the WQIP. An additional field site was added--analysis included in Section 4.3.
19	**SMR WMAA/ SECTION 4**	Explain in more detail what the definition of "protected" means with regards to 401 certifications. 401 certifications mitigate impacts and do not necessarily result in avoiding fill conditions in stream systems that are waters of the US and/or State. Describe what NHD Plus channels are and if these are waters of the US and State.	NA	JM	The State Board describes their role under the 401 and Wetlands Programs as follows: This program regulates discharges of fill and dredged material under Clean Water Act Section 401 and the Porter-Cologne Water Quality Control Act. This program protects all waters in its regulatory scope, but has special responsibility for wetlands, riparian areas, and headwaters because these waterbodies have high resource value, are vulnerable to filling, and are not systematically protected by other programs. We are involved with protection of special-status species and regulation of hydromodification impacts. The Program encourages basin-level analysis and protection, because some functions of wetlands, riparian areas, and headwater streams - including pollutant removal, flood water retention, and habitat connectivity - are expressed at the basin or landscape level. In general, channels subject to regulation under Clean Water Act Section 401 would be protected through the Regional Board's review and approval of the regulated activity and compliance with the conditions set forth in the Water Quality Certifications. The NHDPlus channels is GIS stream network developed by USGS. http://www.horizon-systems.com/nhdplus/

			Code	**By Whom**	**Response**
20	**SMR WMAA/ SECTION 4**	Explain in more detail the driving factors for the results and statements with regard to the river reach being stable. Merely stating that an x, y z number is less than another number is not transparent and inadequate discussion to support the exemption.	C	JM	The District will seek consultant to clarify discussion regarding channel stability. The District will coordinate a meeting with the Regional Board to discuss scope of analysis after the submittal of the WQIP. Additional details regarding the analysis were added in Section 4.
21	**SMR WMAA/ SECTION 4**	Provide a substantiated numeric based explanation that the SMR exemption will not affect or impair the efforts to restore the beneficial uses to the estuary. The effects the stakeholder group are looking at are hydromodification effects, nutrients, loss of canopy, sediment, toxicity. The group has indicated that potential issues may occur from rising groundwater. Have the Copermittees discussed the analysis of this exemption with the stakeholders (ie Camp Pendleton, SCCWRP) and resolved any comments on the assumptions and conclusions? Other issues may be additional volume, fresh water input, and increased velocity. It does not appear that the analyses looked at this reach as a system that included the estuary. The appropriate technical information from the stakeholder group should be included in this assessment.	A	JM	The wet weather discussion in section 4.3.3 has been revised to provide WASP Model results from the Model Application Report. The Consultation Committee, which includes most of the members from the stakeholder group, San Diego County Co-Permittees, Riverside County Co-Permittees, San Diego Regional Water Quality Control Board, Camp Pendleton, and the Sierra Club all were given the opportunity to express their concerns about the Hydromod Exemptions included in the WMAA.
22	**SMR WMAA/ SECTION 4**	It does not make sense that upstream HMP controls would occur if this reach has exemption from HMP controls. ON what basis is this conclusion made?	A	JM	The wet weather discussion in section 4.3.3 has been revised to better explain the HMP controls.
23	**SMR WMAA/ SECTION 4**	Murrieta creek is stabilized with soil – cement (concrete) and is not “other than concrete”. Hence the on-site concrete batch plant for this project.	A	JM	Materials other than concrete used in Murrieta Creek include: riprap, turf reinforcement or vegetation.
24	**SMR WMAA/ SECTION 4**	It is unclear if the upstream area is 149 or 220 square miles.	A	JM	The following text was deleted from table in Section 4.5.2: (If the areas upstream of the lakes are included the area is 220 sq. miles).
25	**SMR WMAA/ SECTION 4**	It is not clear what the conclusion is if the channel slopes are soil cement and not turf. Is the shear stress greater?	A	JM	Yes, the shear stress for reinforcement mat, soil cement protection, or rip-rap, all of which have critical shear stress greater than or equal to 8 pounds per square foot (lb/ft2), are greater than the value needed to maintain a stable creek. A greater stream shear stress endure/sustains a stronger force.
26	**SMR WMAA/ SECTION 4**	What are the future conditions for Murrieta Creek?	A	JM	The future condition includes the completion of the Murrieta Creek Flood Control, Environmental Restoration and Recreation Project.

27	SMR WMAA/ SECTION 4	What is a “synthetic record”?	A	JM	In this case, the synthetic record means the modeled or analytically-derived series of hydrology parameters such as flow rate and duration of flow at points or nodes in the system. Available measured parameters such as precipitation, catchment area, catchment slopes, channel conditions, etc., are used as inputs to the model or algorithm; the synthetic record is a model output.
28	SMR WMAA/ SECTION 4	What increase in impervious area is assumed? Would additional increases mean that this reach is not stable?	A	JM	The increased impervious area comes from the future landuse data. Future land use data is used to determine the erosion potential and the sediment supply potential, the calculations used to Evaluate Hydromodification Management Exemptions.
29	SMR WMAA/ SECTION 4	If there is erosion and scour potential of the existing established mitigation area downstream of the project, how is this considered a stable stream reach and a basis for an exemption of flow controls in the drainage area?	A	JM	The occurrences of erosion and scour are expected to be within the range of current conditions. It is anticipated that the larger trees would remain in place once established; however, the smaller trees and shrubs may be washed out during significant storm events. Natural recruitment is expected within areas of scour as has occurred within the Phase I area, where riparian and wetland vegetation within the channel invert has re-established after completion of construction.
30	SMR WMAA/ SECTION 4	Factors of Safety: All projects are required to implement LID in the WMA even if they are exempt from flow controls. Priority development projects must fully implement onsite retention. If the project cannot retain what is required, they must mitigate through off site compliance. Without an AC program, the projects cannot meet the permit requirements.	NA	JM	Thank you for the clarification.
31	SMR WMAA/ SECTION 4	The WQIP is using the likely, unlikely etc potential stressors. Can these reaches be assessed with this information from SCCWRP?	A	JM	The reaches were assessed using the methods described in SCCWRP Technical Report 605, 2010.
32	SMR WMAA/ SECTION 4	How is the WQE guidance used in this assessment?	A	JM	The WMAA combined with the San Diego Water Quality Equivalency guidance can be used to provide flexibility with meeting the Permit’s land development requirements.
33	HRU/CCSY	It is unclear why the national forest was left out when tribal lands were included in the WMA area analyses for the upper WMA.	A	VSS	The entire upper SMR watershed was analyzed; text revised.

Table 3. List of Title 22 Constituents

Inorganics	VOCs	SOCs	Secondary
Aluminum	Benzene	Alachlor	Color
Antimony	Carbon Tetrachloride	Atrazine	Foaming Agents (MBAS)
Arsenic	1,2-Dichlorobenzene	Bentazon	Iron
Asbestos	1,4-Dichlorobenzene	Benzo(a)pyrene	Manganese
Barium	1,1-Dichloroethane	Carbofuran	Odor
Beryllium	1,2-Dichloroethane	Chlordane	Silver
Cadmium	1,1-Dichloroethylene	Dalapon	Thiobencarb
Chromium	Cis-1,2-Dichlorethylene	Dibromochloropropane	Turbidity
Copper	Trans-1,2-Dichloroethylene	Bis(2-ethylhexyl)adipate	Zinc
Cyanide	Dichloromethane	Bis(2-ethylhexyl)phthalate	Total Dissolved Solids
Fluoride	1,3-Dichloropropene	2,4-D	Chloride
Hexavalent Chromium	1,2-Dichloropropane	Dinoseb	Sulfate
Lead	Ethylbenzene	Diquat	
Mercury	Methyl-tert-butyl ether (MTBE)	Endothall	
Nickel	Monochlorobenzene	Endrin	
Nitrate	Styrene	Ethylene Dibromide	
Perchlorate	1,1,2,2-Tetrachloroethane	Glyphosate	
Selenium	Tetrachloroethylene	Heptachlor	
Thallium	Toluene	Heptachlor Epoxide	
	1,2,4 Trichlorobenzene	Hexachlorobenzene	
	1,1,1-Trichloroethane	Hexachlorocyclopentadiene	
	1,1,2-Trichloroethane	Lindane	
	Trichloroethylene	Methoxychlor	
	Trichlorofluoromethane	Molinate	
	1,1,2-Trichloro-1,2,2-Trifluoroethane	Oxamyl	
	Vinyl chloride	Pentachlorophenol	
	Xylenes	Picloram	
		PCBs	
		Simazine	
		Thiobencarb	
		Toxaphene	
		2,3,7,8-TCDD (Dioxin)	
		2,4,5-TP (Silvex)	
		Total Trihalomethanes

Table 1. Other Types of Data Reviewed as Part of Source Identification Efforts

Special Study Title	Type of Data	Notes
Eutrophication and Nutrient Cycling in Santa Margarita River Estuary: A Summary of Baseline Studies for Monitoring Order R9-2006-0076	Algal biomass and percent cover, dissolved oxygen, total nitrogen and total phosphorus concentrations and fluxes between water and sediment.	SMRNIG Study, See Section **Error! Reference source not found.**.
Status of Eutrophication over a Two Year Period (2015-2016) in Lower Santa Margarita River, San Diego, California (SMRNIG Phase I data report)	Benthic algal abundance, benthic organic carbon, dissolved oxygen, pH, total nitrogen and total phosphorus concentrations, stream velocity, depth, discharge, channel substrate and riparian canopy cover.	SMRNIG Study, See Section **Error! Reference source not found.**. Two year study in three portions of river.
Santa Margarita River Watershed Phase II-Sediment and Nutrient Calibration Memorandum	Results of Watershed Loading Model calibration for nitrogen and phosphorus.	SMRNIG Study, See Section **Error! Reference source not found.**.
Calibration of Linked Hydrodynamic and Water Quality Model for Santa Margarita Lagoon	Results of estuary model calibration for algae, dissolved oxygen, nitrogen and phosphorus.	SMRNIG Study, See Section **Error! Reference source not found.**.
Application of watershed loading and estuary water quality models to inform nutrient management in the Santa Margarita River Watershed.	Results of using the watershed loading model and estuary model to inform major science objectives for the SMRNIG, including understanding the major pathways that supply nutrients to the SMR Estuary, estimate the range of allowable loads to the SMR Estuary, evaluate potential numeric targets, identify preliminary scenarios for evaluating nutrient management, and estimate sources of nutrients to SMR Estuary.	SMRNIG Study, See Section **Error! Reference source not found.**.
Agricultural, Federal, Tribal, and State Input Special Study, 2014 Annual Progress Report	Monitoring data for the following parameters: physical chemistry, bacteriological, conventionals, nutrients and hydrocarbons, pesticides, and total and dissolved metals.	Source information for agricultural, federal and tribal land uses.

Special Study Title	Type of Data	Notes
Hydromodification Monitoring Project	Channel and bank conditions (gradient, particle size, channel width), location of discharge points, habitat integrity (individual CRAM attribute scores and selected parameters from SWAMP stream physical habitat characterization), quantification of bank eroded areas, and vertical and lateral susceptibility ratings.	Three monitoring locations. Not directly relevant to the identification of sources/stressors related to nutrients.
Sediment Toxicity Special Study, Santa Margarita Region, 2013-2014 Final Report	Analytical results for particle size, general chemistry, trace metals, organochlorine pesticides, and synthetic pyrethroids. Acute and chronic solid phase toxicity bioassay results, rapid stream bioassessment results (including IBI scores for 4 reaches).	Not directly relevant to the identification of sources/stressors related to nutrients.
Source Assessment of Iron and Manganese for the Santa Margarita Region	Summary statistics for the following: iron and manganese concentrations in groundwater, SMR reference streams, atmospheric deposition mass loads from wet weather monitoring data, and TSS and TDS concentrations in SMR urban receiving waters.	Not directly relevant to the identification of sources/stressors related to nutrients.
Trash and Litter Investigation Special Study	Number and type of trash items for two wet and two dry events. Rapid trash assessment overall scores and ratings. Evaluations of trash and litter BMPs currently in place.	Not directly relevant to the identification of sources/stressors related to nutrients.
Pharmaceuticals and Personal Care Products in the Streams and Rivers within the San Diego Region, Pilot Study, California Regional Water Quality Control Board, San Diego Region, May 10, 2016.	The study was designed to investigate the presence of Pharmaceuticals and Personal Care Products (PPCPs) in the region and monitored discharges from POTWs and several sites in surface waters focusing on PPCPs.	The study monitored discharges from POTWs and surface waters. The results do not provide useful information related to sources of pollutants entering or discharging from the MS4. Further, the study focuses on PPCPs and does not include monitoring of constituents related to eutrophication or nutrients. The study does identify caffeine as a potential surrogate for detecting human waste, which can

Special Study Title	Type of Data	Notes
		contribute nutrient loads, but concludes that caffeine alone should not be used as the only tracer for leaking sewer lines or septic tank systems.
Cost Benefit Analysis - San Diego Region Bacteria Total Maximum Daily Loads	Information on potential sources of bacteria and human waste to receiving waters in the San Diego Region and potential BMPs.	Multiple sources of human waste are identified which could contribute nutrients to receiving waters. Potential sources include sanitary sewer collections systems, OWTS, and homeless encampments. The study did not include the Santa Margarita River Watershed.
Bioassessment of Perennial Streams in Southern California: A Report on the First Five Years of the Stormwater Monitoring Coalition's Regional Stream Survey	CSCI scores, diatom index (D18), soft algae index (S2), and CRAM scores. Summary statistics for water chemistry, toxicity, physical habitat, and stress prioritization.	Dataset utilized by this report has been incorporated into the receiving water condition assessment. Data is not directly relevant to the identification of sources/stressors related to nutrients
Santa Margarita River Lagoon Monitoring Project	Monitoring data for the following parameters: ammonia, nitrate/nitrite as N, nitrite as N, total nitrogen, and total phosphorus.	One monitoring location in the SMR Estuary. Not directly relevant to the identification of sources/stressors related to nutrients
2011 Long-Term Effectiveness Assessment (LTEA), San Diego Copermittees	Watershed priority constituents determined by Water Quality Assessment Monitoring Program; trends assessments; source attribution,	The 2011 LTEA characterized the source loading potential for various areas and activities across the San Diego Region.
Transitional Monitoring and Assessment Program Report for the Santa Margarita River Watershed Management Area (2014 - 2015)	Dry and wet weather receiving water trends.	One monitoring location
Monitoring Reports submitted under Agricultural Waiver, Upper SMR Irrigated Lands Group	General chemistry, wet and dry events.	Supplemented by loading estimates as characterized through SMRNIG modeling efforts. See Section **Error! Reference source not found.**.
Caltrans Public Education Litter Monitoring Study 2001-2002	Summary of results from storm water litter monitoring study conducted during the	Not directly relevant to the identification of sources/stressors related to nutrients.

Special Study Title	Type of Data	Notes
	2000 to 2001 storm season in Caltrans District 7.	
Caltrans Stormwater Monitoring and Research Program, Annual Data Summary Report 2002, 2008	Summary of all data generated from the Caltrans Stormwater Monitoring and Research Program during the 2006 to 2007 storm season for the following constituents: conventionals, nutrients, metals, hydrocarbons, and microbiologicals.	Supplemented by loading estimates as characterized through SMRNIG modeling efforts. See Section **Error! Reference source not found.**.
Caltrans Discharge Characterization Study Report (November, 2003)	Summary statistics of the following monitored constituents: conventional parameters (pH, temperature, TSS, TDS, conductivity, hardness, total organic carbon, and dissolved organic carbon), nutrients (nitrate, total kjeldahl nitrogen (TKN), orthophosphate-P, and TP), and total and dissolved metals (arsenic, cadmium, chromium, copper, lead, nickel, and zinc).	Supplemented by loading estimates as characterized through SMRNIG modeling efforts. See Section **Error! Reference source not found.**.
Caltrans Construction Sites Runoff Characterization Study Monitoring Seasons 1998-2002	Seasonal mean values of total and dissolved metals, and nutrients, conventional pollutants.	Supplemented by loading estimates as characterized through SMRNIG modeling efforts. See Section **Error! Reference source not found.**.
Geotracker Site 1120 T10000004268 (Camp Pendleton Marine Corps Base Site – 1120 Stuart Mesa)	Pesticides and metals analysis.	Data obtained from Geotracker Site did not include any nutrient data to evaluate this location as a source of nutrients. However, as shown in **Error! Reference source not found.**, modeling work performed as part of the SMRNIG demonstrates that this site may be a significant source of nutrients in the Lower SMR Subwatershed.

Appendix 3B – Potential Strategies to Address the HPWQC

** This Page Intentionally Left Blank **

Appendix 3B.
Potential Water Quality Improvement Strategies

Permit Provision B.2.e requires Copermittees to identify potential strategies that can result in improvements to water quality in MS4 discharges and/ or receiving waters. The Permit stipulates that structural and non-structural BMPs, including incentive or other programs, may be implemented within the SMR WMA to address the HPWQC; retrofits may be implemented to reduce MS4 sources of pollutants or stressors, and rehabilitation may be implemented to protect and/or improve conditions in receiving waters.

It is expected that a phased approach to implementation will be based primarily on non-structural solutions, with structural solutions considered where non-structural approaches are not demonstrating achievement of goals.

Considering that some strategies can address similar sources, the sources were grouped into the following land use categories:

- Residential areas and activities;
- Commercial/Industrial;
- Parks and recreation;
- Orchards, Vineyards, Nurseries, and other Agriculture; and
- Horse Ranches.

RESIDENTIAL AREAS AND ACTIVITIES

Residential land uses make up approximately 35% of the land uses in the SMR watershed. Coupled with approximately 20-70% of the dry weather loading to the MS4, depending on the jurisdiction, these areas will be one of the key sources addressed by the implementation strategies ultimately selected by the Copermittees. Sources of nutrients within residential areas generally focus on landscape maintenance (e.g., fertilizer application) and irrigation, with irrigation return flows being the main transport mechanism for nutrients. In the areas of the watershed where there is a predominance of residential sources, eutrophication and nutrient loading are a dry weather issue, so strategies are generally focused on areas and activities under the dry condition. While the potential strategies have been developed to address eutrophication and nutrients, many of them will directly address sources of dry weather flow, thereby providing reductions for constituents affecting priority water quality conditions as well (e.g., bacteria reductions will benefit recreational uses). Key potential strategies to address eutrophication and nutrient loading from residential areas during dry weather are included in **Table 1**.

COMMERCIAL/INDUSTRIAL

Commercial land uses make up only 1% of the land uses in the SMR watershed but these areas have the potential to contribute approximately 1-13% of the nutrient loads in the watershed during dry weather. Although not as prevalent as residential areas, these areas are one of the more significant sources in several jurisdictions and will be addressed by implementation strategies. (Of note, commercial and industrial sources are not inclusive of commercial nurseries for the purposes of the source characterization and strategy selection.) Sources of nutrients within commercial areas generally focus on landscape maintenance (e.g., fertilizer application) and irrigation, with irrigation return flows being the main transport mechanism for nutrients. However depending on the type of commercial or industrial facilities, other outdoor areas and activities have the potential to contribute to nutrient loading. Examples include materials storage (e.g., fertilizers, compost), waste storage (e.g., trash, grease areas), illegal washing (e.g., restaurant mats), and illegal dumping (e.g., mop water). In the areas of the watershed where there are many commercial sources, eutrophication and nutrient loading are a dry weather issue, so strategies are generally focused on areas and activities under the dry condition. While the potential strategies have been developed to address eutrophication and nutrients, many of them will directly address sources of dry weather flow, thereby providing reductions for constituents affecting priority water quality conditions as well. Key potential strategies to address eutrophication and nutrient loading from commercial and industrial areas during dry weather are included in **Table 1**.

PARKS AND RECREATION

Parks and recreation land uses make up only 1% of the land uses in the SMR watershed. These areas also have relatively low estimated dry weather loads (0-2.5%) but are often owned and maintained directly by Copermittees within the watershed. Therefore, where parks and recreation areas are significant contributors, jurisdictions will implement strategies to address these sources. Sources of nutrients within parks and recreation areas are similar to residential areas, and generally focus on landscape maintenance (e.g., fertilizer application) and irrigation, with irrigation return flows being the main transport mechanism for nutrients. In the areas of the watershed where there are parks and recreation related sources, eutrophication and nutrient loading are a dry weather issue, so strategies are generally focused on areas and activities under the dry condition. While the

potential strategies have been developed to address eutrophication and nutrients, many of them will directly address sources of dry weather flow, thereby providing reductions for constituents affecting priority water quality conditions as well. Key potential strategies to address eutrophication and nutrient loading from parks and recreation areas during dry weather are included in **Table 1**.

ORCHARDS, VINEYARDS, NURSERIES, AND OTHER AGRICULTURE

Agricultural land uses comprise approximately 7% of the land uses in the SMR watershed. Orchards, vineyards, nurseries, and other agriculture discharging to the MS4 may be subset of the 7% but can also fall within residential areas of the watershed. Estimates are that these uses contribute as little as 0% of the loading in some jurisdictions but as much as 56% in others, depending on the distribution of these sources. Where orchards, vineyards, nurseries, and other agricultural areas are significant contributors of nutrient loading to the MS4, jurisdictions will implement strategies to address these sources. In area such as Rainbow Creek, strategies focusing on commercial nurseries will be significant in addressing nutrient loads. Sources of nutrients within orchards, vineyards, nurseries, and other agricultural areas generally focus on irrigation return flows being the main transport mechanism for nutrients. However, in Rainbow Creek, these sources have been show to contribute nutrient loads in wet weather as well. While nutrient loading from these areas will generally be addressed by strategies focused on dry weather, strategies in Rainbow Creek will address both dry and wet conditions. Many of the strategies will directly address sources of nutrient loading under dry and wet conditions (e.g., flow and materials storage, respectively), but will also provide reductions for constituents affecting priority water quality conditions (e.g., bacteria in dry weather flow, transport of trash or pesticides in wet weather). Key potential strategies to address eutrophication and nutrient loading from orchards, vineyards, nurseries, and other agricultural areas during dry and wet weather are included in **Table 1**.

HORSE RANCHES

Horse ranches are a unique land use that may fall under the general umbrella of agricultural land uses (7% of the land uses in the SMR watershed) or under residential land uses. Loading estimates during dry weather range from 0 – 10% depending on their prevalence within the jurisdiction. Where horse ranches are significant contributors of nutrient loading to the MS4, jurisdictions will implement strategies to address these sources. Nutrients coming from horse ranches could be from a variety of sources, but in dry weather would most likely focus on irrigation return flows being the main transport mechanism for nutrients. Other sources could include material storage (e.g., manure storage or compost) and illegal washing within facilities. Many of the strategies will directly address sources of nutrient loading under dry conditions (e.g., irrigation flows, illegal washing), but may also provide benefits in wet weather (e.g., material storage), and will provide reductions for constituents affecting priority water quality conditions (e.g., bacteria in dry weather flow). Key potential strategies to address eutrophication and nutrient loading from horse ranches during dry weather are included in **Table 1**.

Table 1. Key Potential Strategies to Address Eutrophication and Nutrient Loading from Source Categories

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Illicit Discharge, Detection, and Elimination (IDDE) Program (Prov D.2, E.2)					
Maintain storm water conveyance system map to facilitate IDDE program.	X	X	X	X	
Utilize municipal personnel and contractors to identify and report Illicit Connections and Discharges.	X	X	X	X	X
Updated focused training for municipal field staff.	X	X	X		
Address septic system failures where observed.	X	X	X	X	
Facilitate public reporting of incidental observation of Illicit Connections and Illicit Discharges (e.g., via email).	X	X	X	X	X
Bilingual hotline to provide better customer service.	X	X	X	X	X
Implement practices and procedures to address spills with the potential to enter the storm drain system.	X	X	X	X	X
Utilize municipal personnel and contractors to monitor storm water outfalls for discharges of potential Illicit Connections and Illicit Discharges.	X	X	X	X	X
Develop and implement a strategy for investigating and addressing Illicit Connections and Illicit Discharges.	X	X	X	X	X
Implement an inspection and enforcement program to ensure compliance with regulation and IDDE requirements.	X	X	X	X	X
Refer homeless issue complaints to law enforcement or appropriate jurisdictions.	X	X	X	X	X
Respond to homeless issue complaints with law enforcement and other agencies to remove trash and debris.	X	X	X	X	X
Responsible Compassion for the Homeless Program to address homeless problems throughout the jurisdiction, thereby reducing their impacts on water quality through trash, illegal dumping, and direct discharge of human waste.	X	X	X	X	X

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Plot IDDE incidents in GIS to identify clusters where targeted education, community outreach, or workshops may be effective in eliminating dry weather flows.	X	X	X	X	X
Update ordinances to reflect current illicit discharge and connections requirements and strategies.	X	X	X	X	X
Develop a standardized approach to allow staff to more efficiently identify and report IDDE incidents.	X	X	X	X	X
Enhanced municipal training programs and curriculum targeting key field staff. Programs will focus on the water quality improvement plan, HPWQCs, NNE requirements as related to illicit discharges and elimination of dry weather flows.	X				
Implement a District right-of-way inspection program to identify and report Illicit Connections and Discharges.	X	X			
Respond, educate and require mitigation on septic system failures where observed. Coordinate investigations with regulatory agency for septic systems. Focus on elimination of nutrient loading from phosphorus sources and bacteria loading to MS4 from septic failure. Educate property owners on proper septic maintenance and the importance of eliminating discharges to the MS4.	X	X	X	X	
Post signage adjacent to open channels providing information to report any observed illicit discharges. Signage will focus on sources of non-stormwater discharges such as illegal dumping and over-irrigation.	X	X	X	X	
Development Planning (Prov D.2)					
Priority Development Projects (PDPs): In addition to requirement for all development projects, implement or require implementation of onsite structural BMPs to control pollutants and manage hydromodification for PDPs.	X	X	X	X	X
Update BMP Design Manual procedures to specify storm water requirements applicable to development and redevelopment projects, identify and design appropriate BMPs, establish maintenance criteria, and establish where implemented alternative compliance options.	X	X	X	X	X

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Conduct internal (staff) training on the updated BMP Manual.	X	X	X	X	X
Impose legal authority to ensure all development and redevelopment projects are in compliance with all post construction requirements.	X	X	X	X	X
Update codes, ordinances, and storm water design standards consistent with the permit and the updated BMP Manual.	X	X	X	X	X
For all development projects, administer a program to ensure implementation of source control BMPs to minimize pollutant generation at each project and implement LID BMPs to maintain or restore hydrology of the area, where applicable and feasible.	X	X	X	X	X
Smart Irrigation Conditions of Approval	X	X			
Revised post-construction guidelines to eliminate dry weather discharges from new and redevelopment	X	X			
Require new development projects to develop and submit a Storm Water Quality Training Manual for employees.		X			
Delineate Jurisdictional Areas on Development Plans	X	X	X	X	X
Update BMP Design Manual to include soil mix specifications for Bioretention BMPs to retain nutrients.	X	X	X	X	X
Prepare drought tolerant Guidelines and Standards for new development and BMP retrofits (e.g. water smart irrigation controllers, turf replacements programs, residential landscape evaluation program).	X	X	X	X	X
Develop a NPDES DATA FORM for Design Teams to identify project-related NPDES data to facilitate: identification of HPWQC and PWQP sources, analyze HPWQC and PWQP source reduction in CEQA/NEPA document, and design of post-construction BMPs to address HPWQC and PWQPs loading reduction and hydromodification.	X	X	X	X	X

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Modified Low Impact Development requirements for new and redevelopment to specifically address nutrients during dry and wet weather through increased use of disconnected impervious surfaces, on-site retention of dry weather flows, and treatment of stormwater prior to discharge.	X	X	X	X	X
Construction Management (Prov E.4)					
Require implementation of BMPs that are site specific, seasonally appropriate and appropriate to the construction phase, year round.	X	X	X	X	X
Impose legal authority to ensure inventoried construction projects are in compliance with all requirements.	X	X	X	X	X
Provide internal staff training related to construction storm water management.	X	X	X	X	X
Administer a program to oversee implementation of BMPs during the construction phase of land development. Includes inspections at an appropriate frequency and enforcement of requirements.	X	X	X	X	X
Implement, or require the implementation of, enhanced construction BMPs on specific projects.	X	X	X	X	X
Provide enhanced focus on specific items during construction inspections.	X	X	X	X	X
Delineate Jurisdictional Areas on Project Sites	X	X	X	X	X
Make updates to ordinances related to construction; reference to existing grading ordinance and requirement to implement enhanced BMPs to mitigate erosion and dry weather flows to MS4 and receiving waters in the SMR.	X	X	X	X	X
Ensure grading activities are classified as HIGH priority if land is surrounded by or was previously used for agricultural operations.				X	
Existing Development Management (Prov E.5)					
Maintain and update a watershed-based inventory of existing development (i.e. commercial, industrial, municipal and residential areas).	X	X	X		

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Improve the tracking of watershed based inventories via consolidated database.	X	X	X	X	X
Designate a minimum set of BMPs required for all existing development inventories, including special event venues. The designated minimum BMPs must be specific to facility or area types and pollutant generating activities, as appropriate.	X	X	X	X	X
Pet waste management and outreach.	X		X		
Implement a schedule or operation and maintenance activities for the storm water conveyance system and related structures.	X	X	X	X	X
Implement a schedule of operation and maintenance for paved and unpaved roads.	X	X	X	X	X
Promote and encourage implementation of designated BMPs in residential areas.	X				
Conduct inspections of inventoried existing development to ensure compliance.	X	X	X	X	X
Conduct focused residential inspections based on strategic assessments.	X				
Develop a residential inspection tracking program via mobile platform - miles, violations, etc.	X				
Improve inspections data tracking through mobile phone applications.	X	X	X	X	X
Enforce legal authority established for all inventoried existing development to achieve compliance.	X	X	X	X	X
Promote incentive program for BMP retrofits (e.g. water smart irrigation controllers, turf replacements programs, residential landscape evaluation program).	X	X	X	X	X
Turf replacement in parks.			X		
Promote the implementation of equestrian BMPs and distribute outreach material.					X
Notify Regional Board of industrial businesses subject to the Industrial General Permit so that the businesses may obtain coverage as required.		X			

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Adjustments to street sweeping frequencies and routes, as determined by jurisdiction.	X	X			
Enhanced municipal training programs and curriculum targeting key field staff. Programs will focus on the water quality improvement plan, HPWQCs, NNE requirements as related to illicit discharges and elimination of dry weather flows.	X	X	X	X	X
Install weather based irrigation controllers in public landscaped areas.			X		
Enhance commercial/industrial/municipal inspections programs to focus on irrigation systems.		X			
Enhance residential inspections programs to focus on over-irrigation.	X				
Increase inspection frequencies at facilities identified on Copermittee inventories to be sources of nutrients	X	X		X	
Maintain the as-built capacity/lines and grades of existing flood control facilities. Maintenance activities include sediment and debris removal, slope and erosion repairs, side-slope tracking and/or reshaping, vegetation maintenance, structure rehabilitation and/or replacement, rip-rap and grout repair, removal and replacement of concrete channel linings, and washout backfill and repair.	X	X	X	X	X
Inspection and outreach program to eliminate dry weather flows from target areas	X	X	X	X	X
HAZMAT Response Program support	X	X	X	X	X
Enhance the Business Registration Program by educating owners on Nutrient and other PWQP source reduction.		X			
Require implementation of BMPs to address application, storage, and disposal of pesticides, herbicides, and fertilizers on commercial, industrial, agricultural (e.g., large commercial nurseries), residential, and municipal properties. Includes education, verifying permits and certifications.	X	X	X	X	

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
Enforcement Response Plans (Prov E.6)					
Implement escalating enforcement responses to compel compliance with ordinances, permits, contracts, orders, and other requirements for IDDE, development planning, construction management, industrial/commercial, municipal, and residential development (including residential equestrian and livestock activities)	X	X	X	X	X
Enforce Legal Authority on development projects to ensure that projects comply with post-construction BMP requirements.	X	X			
Implement Enforcement Response Plan, per JRMP, to address IDDE incidents.	X	X			
Require the use of BMPs to prevent or reduce the discharge of Pollutants into the MS4 from Stormwater	X	X	X	X	X
Ensure that private construction activities comply with the Construction General Permit and Copermittees' Stormwater Ordinances.	X	X	X	X	X
Enforce escalating legal authority established for all inventoried existing development, including residential and agricultural, to conserve water and eliminate dry weather flows. Verbal warnings shall be tracked along with written escalating enforcement.	X	X	X	X	X
Report suspected agriculture operation "non-filers" to the Regional Board promptly. Maintain database of reported "non-filers".				X	X
Public Education and Participation (Prov E.7)					
Implement a public education and participation program to promote and encourage development of programs, management practices and behaviors that reduce the discharge of pollutants in storm water prioritized by high risk behaviors, pollutants of concern, and target audiences.	X	X		X	
Educational Workshops on Integrated Pest Management, manure management and others as needed.	X	X	X	X	X
Collaborate with watershed partners to develop consistent messaging to targeted audiences, such as	X	X			

Potential Strategy	Source Categories				
	Residential	Commercial/ Industrial	Parks and Recreation	Orchards, Vineyards, Nurseries, and other Agriculture	Horse Ranches
commercial residents to conserve water and reduce dry weather flows.					
Outreach to mobile landscaping service providers.	X	X			
Give outreach presentations to elementary, middle, and high school students.	X				
Provide municipal staff training.	X	X	X	X	X
Enhanced outreach programs targeting nurseries				X	
Enhanced outreach programs targeting animal facilities				X	X
Enhanced outreach programs targeting homeowner's associations/residential communities.	X				
Coordinate/develop outreach materials in support of Co-Permittee enhanced inspection, outreach & enforcement programs	X	X	X	X	X
Develop a webpage	X	X	X	X	X
Private Property Watercourse Management Fact Sheet	X	X	X	X	X
Implement pet waste management outreach in parks for resident pet owners.	X		X		
Stock public counters at municipal offices with Pollution Prevention Public Education brochures. Brochures should highlight the importance of proper fertilizer use/application and over irrigation. Other brochures should include emphasis on proper septic maintenance and other good practices to prevent nutrient and other PWQP loading to the MS4 and receiving waters. Provide brochures to other agencies for their public counters as well (e.g., School Administration Buildings).	X	X	X	X	X
Facilitate public reporting, through outreach and public education, of Illicit Connections and Illicit Discharges, including over-irrigation.	X	X	X	X	X
Enhanced outreach materials focused on sources of nutrients (e.g., door hangers, pamphlets, other media). Outreach materials will focus on non-stormwater discharges to the storm drain system (e.g., outdoor water	X	X	X	X	X

1.0 INTRODUCTION

This technical appendix presents the Rainbow Creek Compliance Analysis conducted by Tetra Tech Inc., to support development of the Santa Margarita River Watershed Water Quality Improvement Plan (WQIP). Numeric water quality targets were identified to demonstrate compliance with the Rainbow Creek nutrient TMDL and the County of San Diego's (County's) Municipal Separate Storm Sewer Permit (Permit). A compliance analysis was then conducted to determine the extent of subwatershed-scale strategies needed to achieve the numeric water quality targets.

1.1 SANTA MARGARITA RIVER WATERSHED MANAGEMENT AREA WQIP

A WQIP is currently being developed for the Santa Margarita River Watershed Management Area (WMA) to meet the applicable MS4 permit requirements. To guide and prioritize implementation efforts, the WQIP established a process for identifying the Highest Priority Water Quality Conditions (HPWQCs) in the WMA. This process ranked Rainbow Creek as a HPWQC because Rainbow Creek is the only 303(d) listed water body with an adopted Total Maximum Daily Load (TMDL) in the Santa Margarita River watershed. To address the Rainbow Creek nutrient impairments, a compliance analysis was conducted to identify the recommended water quality improvement strategies and associated planning-level costs.

1.2 COMPLIANCE ANALYSIS SCOPE

Nutrient impairments in Rainbow Creek were identified as the HPWQC for the Santa Margarita River WQIP. A compliance analysis was conducted to demonstrate how the County can comply with the MS4 permit by implementing strategies to achieve the nutrient load reductions necessary to support water quality improvements, especially from developed areas within the County. Baseline nutrient loads, allowable loads, and required load reductions were estimated using the recently updated Santa Margarita HSPF watershed model, which includes the Rainbow Creek watershed. Strategies specifically identified to address nutrient loading in the Rainbow Creek watershed were modeled to demonstrate compliance with the calculated numeric targets. This analysis provides reasonable assurance that the strategies identified will result in the necessary reductions in nutrient loading in the watershed.

The compliance analysis focused first on actionable projects to address runoff both into and from the County's MS4 drainage area. Within each outfall catchment, all areas including residential urban land uses, nurseries, Caltrans and other land uses were identified. To inform comprehensive, watershed-scale decision making, the compliance analysis also identified strategies to address nutrient loading which the County can pursue to improve overall watershed health and meet compliance.

2.0 WATER QUALITY CONDITIONS AND NUMERIC TARGETS

2.1 WATERSHED PROFILE

Rainbow Creek is a tributary to the Santa Margarita River and is located near the unincorporated community of Fallbrook in northern San Diego County (**Figure 2-1**). The Rainbow Creek watershed is designated in the Basin Plan as hydrologic unit subareas (HSAs) 902.22 and 902.23, and encompasses 7,085 acres (San Diego Regional Water Quality Control Board 2005).

Rainbow Creek runs through the middle of Rainbow Valley and the community of Rainbow. Rainbow is the most developed part of the watershed, including residential areas, commercial and private nurseries, and other agricultural operations. While the majority of the watershed is located in San Diego County, a 1,514-acre portion of Riverside County also drains to the creek.

The key sources of nutrients in Rainbow Creek are state highways, agricultural fields and orchards, commercial nurseries, residential and urban areas, and septic tank disposal systems (Figure 2-2). These sources contribute nutrients via stormwater runoff, irrigation return flows, and groundwater contributions to the creek (San Diego Regional Water Quality Control Board 2005).

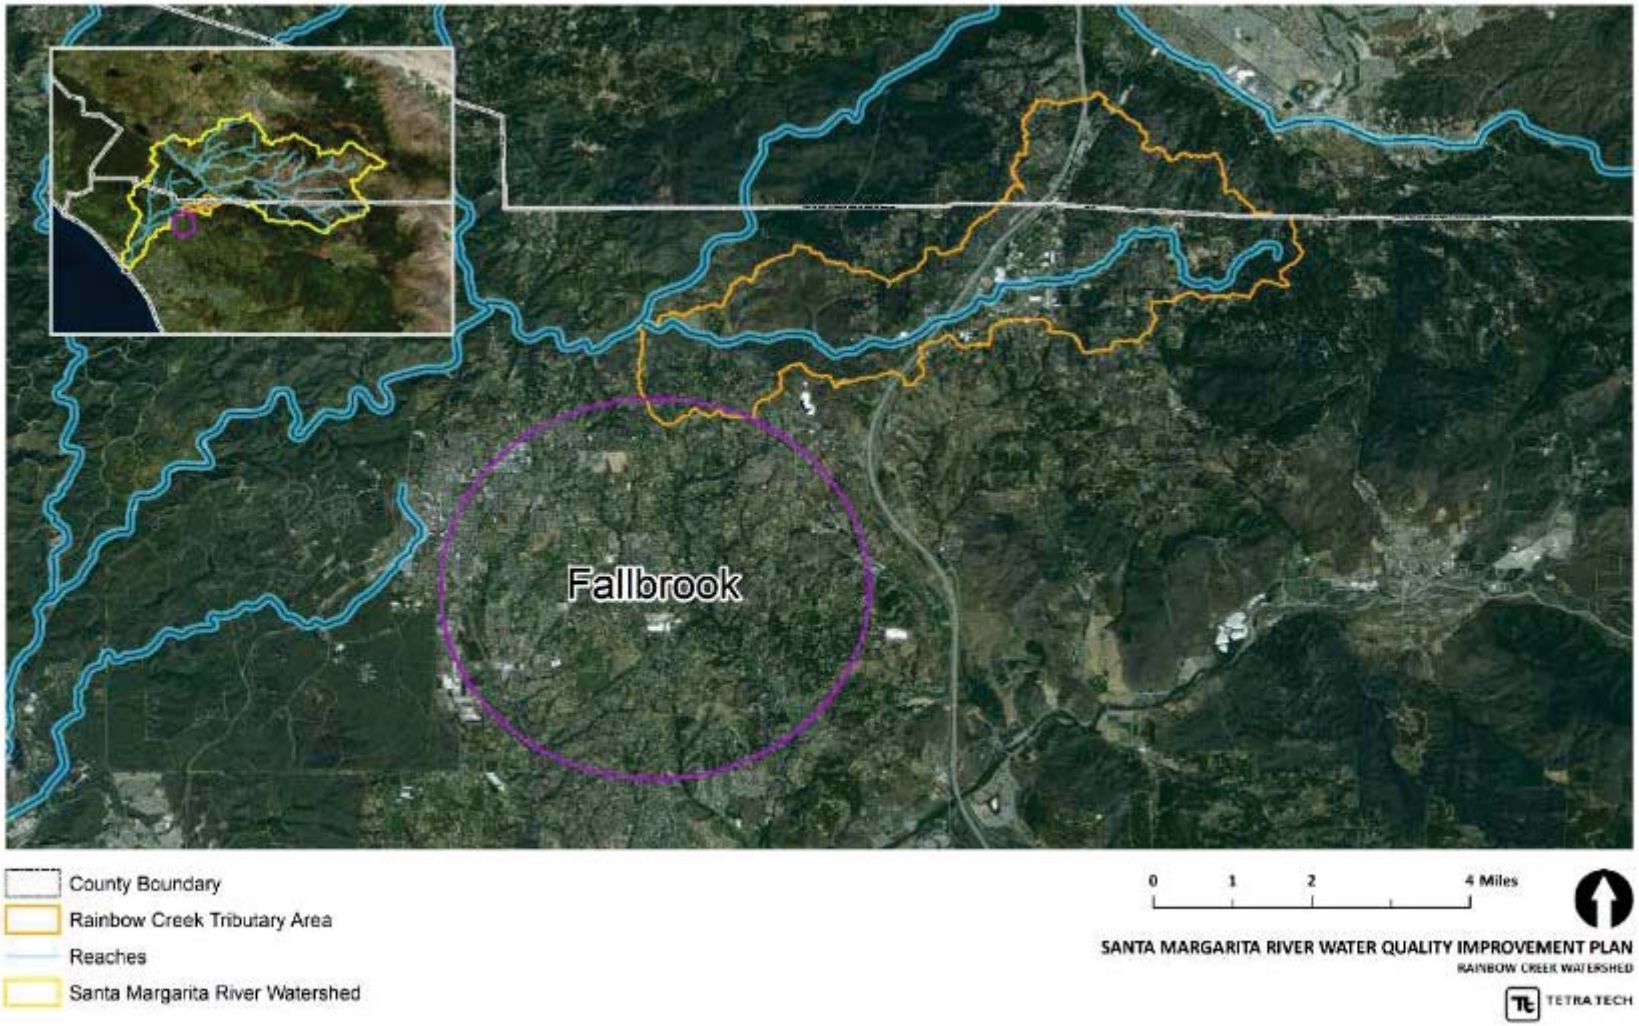

Figure 2-1. Rainbow Creek watershed

2.2 REGULATORY BACKGROUND

This section provides a brief background on the regulations that affect Rainbow Creek and provide the foundation for calculating the WQIP numeric targets. Note that waste load allocations referenced in the MS4 Permit and TMDL, which were established on the basis land use loading data available at the time, are presented for reference only. Updated waste load allocations (and numeric targets) were calculated to support the compliance analysis using the Rainbow Creek output from the recently updated Santa Margarita River watershed model (discussed further in Section 2.3).

2.2.1 Rainbow Creek Watershed TMDL

On February 9, 2005, the San Diego Water Board adopted Resolution No. R9-2005-0036, A Resolution Adopting An Amendment To The Water Quality Control Plan For The San Diego Region (9) To Incorporate Total Maximum Daily Loads (TMDLs) For Total Nitrogen and Total Phosphorus In The Rainbow Creek Watershed, San Diego County (Rainbow Creek TMDL). The affected beneficial uses identified in the TMDL include municipal water supply (MUN), contact and non-contact water recreation (REC-1 and REC-2), warm and cold freshwater habitat (WARM and COLD), and wildlife habitat (WILD). The TMDL numeric targets for nitrate, total nitrogen (TN), and total phosphorus (TP) were set equal to the water quality objectives for municipal water supply (nitrate) and biostimulatory substances (TN and TP) as defined in the Basin Plan (**Table 2-1**).

The Rainbow Creek TMDL indicates that 79% of TN loading and 70% of TP loading are attributable to controllable sources, which include certain land use activities (commercial nurseries, agricultural fields, orchards, residential areas, urban areas, and park areas), septic tank disposal systems (TN only), and Interstate 15 (I-15) (San Diego Regional Water Quality Control Board 2005; **Table 2-2**).

Table 2-1. Rainbow Creek TMDL numeric targets

Constituent	Water quality objective (WQO) = Numeric Target	Note
Nitrate as nitrogen (NO_3-N) [1]	10mg/L	Inorganic nitrate WQO for municipal water supply
Total nitrogen (TN)	1.0mg/L	Numeric goals in the Basin Plan
Total phosphorus (TP)	0.1mg/L	Numeric goals in the Basin Plan

[1] Although the numeric targets are included in the TMDL, LAs and WLAs were not developed for nitrate.

Table 2-2. Rainbow Creek TMDL source assessment

Source	TN Mass Load (kg N/yr)	Percent Contribution (% N)	TP Mass Load (kg P/yr)	Percent Contribution (% P)
Land Uses Runoff	2,662	69	262	66
Background	779	20	116	29
Septic Tank	200	5	0	0
I-15 Runoff (Caltrans)	153	4	14	4
Direct Atmospheric Deposition	40	1	2	1
Combined Sources	3,834	100	394	100

The Rainbow Creek TMDL represents the "amount of a pollutant that a waterbody can receive without violating applicable water quality standards. It is the sum of the allowable loads of a pollutant from all contributing point and nonpoint sources plus a margin of safety" (p. 32 of the Final Technical Report). The TMDL includes the following equations:

- TMDL/load capacity = Margin of safety (MOS) + Background load + ∑(WLA) + ∑(LA)
- Allowable load = TMDL – MOS

The Rainbow Creek nutrient TMDLs were not calculated based on modeling results, rather they were estimated based on a variety of data sources as summarized below (Appendix E to the Final Technical Report includes details on the TMDL technical approach):

- Annual flow volumes were calculated using daily median flow rates from U.S. Geological Service (USGS) records (1989 – 2000; however only data of 8 years were used) for Rainbow Creek near sampling station Willow Glen-4 (Gage No. 11044250)
- 3 flow rate tiers and associated annual flow volumes were developed (**Table 2-3**)
- TMDLs were calculated based on the flow tier results and various nutrient data sources (reference stream monitoring data and land use loading coefficients).

Table 2-3. TN and TP TMDL/load capacity calculation (modified Tables E-3 and E-4 in Appendix E)

Flow tier	Corresponding flow rate (cfs)	Total No. of days (for 8 years)	% of total days	Mean daily flow volume for Tier (cfd)	Avg. No. of days per year	Annual flow volume (cf)	TN TMDL/load capacity[1] (kg/yr)	TP TMDL/load capacity[1] (kg/yr)
Low flow	0-2.9	2,475	86	56,575	314	17,764,622	503	50
Moderate-high flow	3-39	365	12.7	880,546	46	40,775,379	1155	115
Very high flow	>40	37	1.3	9,971,027	5	46,805,255	See footnote[2]	See footnote[2]
Total					365		1,658	165

[1] Numeric target x annual flow volume
[2] Excluded in the TMDL calculation because this flow tier was considered to represent extreme weather conditions

Background loads were estimated via the flow tier approach and reference stream data (Appendix D to the Final Technical Report).

- Calculated based on reference concentrations in San Diego streams and Rainbow Creek annual flow volumes (using the flow tier approach)
- City of San Diego monitoring data from 2001 to mid-2003 at 12 streams and 1997-1998 San Vicente Reservoir study data
- Ammonia, nitrite, nitrate, total Kjeldahl nitrogen, ortho-phosphate, TN, and TP; TN and TP are available only in 2003. For the rest of the years, TN = nitrate + nitrite +TKN
- Average TN concentration = 0.47 mg/L
- Average TP concentration = 0.07 mg/L

Table 2-4. Rainbow Creek TMDL background load calculation

Flow Tier	Annual flow volume (cf)	TN background load (kg/yr)	TP background load (kg/yr)
Low flow	17,764,622	236	35
Moderate-high flow	40,775,379	543	81
Very high flow	46,805,255	See footnote[1]	See footnote[1]
Total		779	116

[1] Excluded in the TMDL calculation because this flow tier was considered to represent extreme weather conditions

Table 2-5. Calculated annual TN/TP surface water loads to Rainbow Creek from various land uses (Tables 4-1 and 4-3 of the Final Technical Report)

Land use	Area (acres [ha])	N-export coefficient (kg/ha/yr)	Annual TN load (kg/yr)	P-export coefficient (kg/ha/yr)	Annual TP load (kg/yr)
Commercial nurseries	339 (137)	3.7	507	0.2	27.4
Agricultural fields	436 (177)	3.7	655	0.2	35.4
Orchards	781 (316)	2.5	790	0.2	63.2
Park	5 (2)	3.4	7	0.1	0.2
Residential	618 (250)	2.6	650	0.5	125
Urban	34 (14)	3.8	53	0.8	11.2
Total	6,591 (2,668)		2,662		262

The Rainbow Creek TMDL includes discussion of the calculation of existing loads in the source assessment section and Appendix F to the Final Technical Report.

- Load Allocations (LAs)
  - Commercial nurseries, agricultural fields, orchards, park, residential areas, and urban areas: using TN/TP export coefficient values from the literature (**Table 2-5**)
  - Septic tank disposal systems: equal to groundwater load (calculated using nitrogen concentration and flow data during dry weather conditions from the Oak Crest-3 Station)
  - Air deposition: TN 40 kg/yr and TP 2 kg/yr; an atmospheric deposition rates of 10 kg N/ha/yr and 0.6 kg P/ha/yr (USEPA 1994) were applied to approximately 4 hectares of the surface area of Rainbow Creek (15 mile length and an average width of 5 ft)
- Waste Load Allocations (WLAs)
  - Caltrans highway runoff: TN and TP concentrations from Caltrans 2003, CTSW-RT-03-065 (3.13 mg N/L; 0.29 mg P/L)
  - Also includes UFPS: 2% of the TMDL – not existing load by the definition

The Rainbow Creek TMDL existing loads, load allocations, and percent reductions are summarized in Table 2-6.

Table 2-6. 2005 Rainbow Creek TMDL existing loads, load allocations, and percent load reductions for TN and TP

	TN				TP			
	Existing load (kg/yr)	*Percent contribution (%)*	Load allocation (kg/yr)	Load reduction (%)	Existing load (kg/yr)	Percent contribution (%)	Load allocation (kg/yr)	Load reduction (%)
WLAs

2.2.2 MS4 Permit Appendix E

On May 8, 2013, the San Diego Water Board adopted Order No. R9-2013-0001; NPDES No. CAS 0109266, National Pollutant Discharge Elimination System (NPDES) Permit and Waste Discharge Requirements for Discharges from the Municipal Separate Storm Sewer Systems Draining the Watersheds within the San Diego Region (MS4 Permit). Appendix E to the MS4 Permit outlines the TMDL compliance requirements (San Diego Regional Water Quality Control Board 2015), which include receiving water and effluent limitations. The TMDL concentrations are the same as the numeric targets in **Table 2-1**. Final effluent limitations were also expressed as annuals loads in MS4 discharges to Rainbow Creek (Table 2-7).

Table 2-7. Final effluent limitations expressed as annual loads in MS4 discharges to Rainbow Creek

Land use	TN (kg/yr)	TP (kg/yr)
Commercial nurseries	116	3
Park	3	0.1
Residential areas	149	12
Urban areas	27	6

Source, Table 3.3 of Attachment E to the MS4 Permit

Compliance with the final WQBELs can be demonstrated via one of the following:

(a) No direct or indirect discharge
(b) No exceedance of the final receiving water limitations (**Table 2-1**) in the receiving water or downstream of MS4 outfalls
(c) No exceedance of the final concentration-based effluent limitations (**Table 2-1**) at the MS4 outfalls
(d) No exceedance of the final load-based effluent limitations (**Table 2-4**) at the MS4 outfalls
(e) WQIP implementation: Demonstrate that implementation of BMPs achieves (a), (b), (c), “and/or” (d) above

2.3 ESTABLISHING NUMERIC COMPLIANCE TARGETS

Since establishment of the Rainbow Creek TMDL, additional water quality monitoring data have been collected to inform the establishment of baseline loading and load reduction targets for areas draining into and from the MS4 in the watershed. This section discusses how the recently updated Santa Margarita River watershed model was used to establish new waste load allocations and numeric targets for the Rainbow Creek compliance analysis. This analysis provides a reasonable assurance that the remedies to be proposed in the Water Quality Improvement Plan will result in satisfying the requirements of the Rainbow Creek Nutrient TMDL.

2.3.1 Updated Watershed Model and Allocations

As part of a stakeholder-led nutrient investigation for the Santa Margarita estuary and river, the HSPF watershed model was recently updated and recalibrated. SCCWRP and Tetra Tech developed a model application report in 2016 that documents the model updates that were completed at the time (Sutula et al. 2016). Since that time, additional model updates were completed to better represent land uses within San Diego County, updated surface water/ground water exchanges based on the Camp Pendleton MODFLOW model, and enhanced weather data to drive the model simulation (Tetra Tech 2017a; Tetra Tech 2017b; Tetra Tech 2017c). This effort included additional calibration of the Rainbow Creek watershed to support the WQIP compliance analysis and future updates to the TMDL. The updated model was used to calculate numeric targets for the Rainbow Creek compliance analysis, rather than using the previously calculated TMDL and MS4 permit nutrient loads and allocations.

Baseline at-source and delivered nutrient loads within the Rainbow Creek watershed were tabulated from the HSPF time-series modeling results. The analysis focused on Water Year (WY) 2003, which is considered to be an "average" or representative water year, consistent with other San Diego Region WQIP compliance analyses. WQIP compliance was determined based on reducing baseline (existing) nutrient loads to meet the estimated allowable loading. Nutrient compliance targets were established based on the receiving water and effluent limitations specified in the TMDL, MS4 permit, and Basin Plan water quality objectives: 1 mg/L for TN and 0.1 mg/L for TP. These limits were tabulated with respect to total hourly flow from the MS4 outfalls to calculate the total allowable loading for WY 2003, and likewise the required reduction.

Numeric compliance targets for the County were, therefore, established by tabulating net at-source (surface runoff) loading and reduction targets, calculated as the difference between modeled loading and hourly sums of allowable loads, given modeled flow rates.

2.3.2 Baseline Loading, Allowable Loads, and Load Reduction Targets

The model and methodology described above were used to generate the baseline loads, allowable loads, and load reduction targets reported in **Table 2-8**, which includes the baseline surface nutrient loading by source from the HSPF model. These data suggest that the majority of at-source loading within the Rainbow Creek watershed stems from non-point sources or areas outside outfall catchments, indicating that nurseries and non-point sources contribute significantly to the total nutrient loading in the Rainbow Creek watershed.

The loads were parsed between outfalls and all other remaining area within the Rainbow Creek watershed (also generically referenced as non-point source loading).

For all areas, only *at-source* surface loading was considered because these loads represent runoff and nutrient contributions that are discharged as "effluent" to receiving waters. The at-source loads also enable equitable comparison between strategies modeled in the following compliance analysis; whereas, the analysis would be confounded if it considered the delivered loads to the watershed outlet (which are influenced by groundwater and surface water loads that originate from point and non-point sources). Furthermore, given the resolution of the modeling system, it was assumed that all at-source surface flow within any catchment area drains to Rainbow Creek, even if the outfall is located upstream.

Table 2-8. Baseline Nutrient Loading, Calculated Allowable Loads, and Load Reduction Targets

Rainbow Creek Area	Area (ac)	Modeled Loading and Numeric Target Summary for WY 2003[1]					
		TN			TP		
		Baseline TN Load (lb)	Allowable TN Load (lb)	Reduction Target (lb and %)	Baseline TP Load (lb)	Allowable TP Load (lb)	Reduction Target (lb and %)
	5,970	5,596	1,421	4,175 (75%)	2,374	153	2,221 (94%)

[1] Metrics represent modeled at-source, surface loading allocated by hydrologic response unit area

In general, the estimated percent load reduction for TN and TP between the current model-based analysis and the Rainbow Creek TMDL (Attachment E to the MS4 Permit) were similar. For example, Table 2-8 shows the TN percent reduction for the outfall catchment area was 65%; whereas, the TMDL percent load reduction for MS4 areas ranged from 50-77% depending on land use type (Table 3.3 in Attachment E of the MS4 permit). TP showed a similar trend, although the current analysis indicated a higher required percent load reduction (92% versus 50-90% in Table 3.3 of Attachment E to the MS4 permit). As expected, estimated baseline loads, allowable loads, and required load reductions are very different between the current model-based analysis and the Rainbow Creek TMDL for various reasons, as discussed in the sections above. Loading estimates based on the recently updated and calibrated HSPF model for Rainbow Creek are expected to be more accurate and appropriate for the WQIP compliance analysis (similar to other WQIPs developed in the San Diego region).

3.0 WATER QUALITY STRATEGIES AND COMPLIANCE ANALYSIS

This section describes the methodology that was used to select, customize, and simulate strategies to achieve the required nutrient load reductions.

3.1 CUSTOMIZED STRATEGIES

A screening-level assessment of the watershed was performed to determine which strategies are most appropriate to address local conditions. This section discusses the recommended strategies and how they were represented in the compliance analysis.

3.1.1 Assessment of Watershed Constraints, Conditions, and Opportunities

To provide a robust and reasonable assurance of compliance, it is essential that the compliance analysis be founded on the basis of opportunities that are actually feasible within the watershed (i.e., instead of allowing the modeling tools to prescribe project types that may not necessarily be appropriate). A desktop assessment was performed to establish this foundation. Soil characteristics, groundwater depth, land use and transportation

typologies, public land availability, and environmental constraints were reviewed to inform the selection of strategies customized to local conditions.

A literature review was also conducted to understand past recommendations for nutrient management in Rainbow Creek. The findings were incorporated into the recommendations in the following subsections. Reviewed references included:

- Rainbow Creek Nutrient Reduction and Management Plan (NRMP): County of San Diego
- Basin Plan Amendment and Final Technical Report for Total Nitrogen and Total Phosphorous Total Maximum Daily Loads for Rainbow Creek
- Santa Margarita River Watershed Management Area Water Quality Improvement Plan, Provision B.2 Submittal: Priority Water Quality Conditions
- San Diego County MS4 Permit Attachment E.3: Specific Provisions for Total Maximum Daily Loads, Total Maximum Daily Loads for Total Nitrogen and Total Phosphorus in Rainbow Creek Watershed

The screening-level assessment revealed that opportunities to improve water quality using public parcels are sparse, with most public land being located in the downstream, less developed areas of the watershed (**Figure 3-1**). This finding implies that non-structural strategies may be essential to address nutrient loads and that distributed, linear control measures within the road rights-of-way may be needed to capture runoff before it discharges to Rainbow Creek (vis-a-vis regional capture strategies, which are not as feasible due to the absence of public parcels in strategic locations to intercept outfall discharges).

Furthermore, soils with poor permeability and high groundwater nutrient concentrations are generally present throughout the watershed indicating that infiltration-based strategies are generally unsuitable (**Figure 3-2**). As a result, infiltration-based strategies were avoided in this particular watershed to protect groundwater supplies from increased nutrient inputs. This means that flow-through and filtration strategies incorporating nutrient-sensitive design elements may be most effective.

Finally, it was observed that the creek itself has been heavily modified and denuded of riparian vegetation in the upper watershed; whereas, the reach downstream from the I-15 freeway remains heavily vegetated. This implies that despite the prevalence of public land in the downstream reach, restoration and in- or near-channel improvements to the upper reaches would likely make progress towards restoring the beneficial uses of Rainbow Creek and were considered important watershed-scale strategies in the compliance analysis.

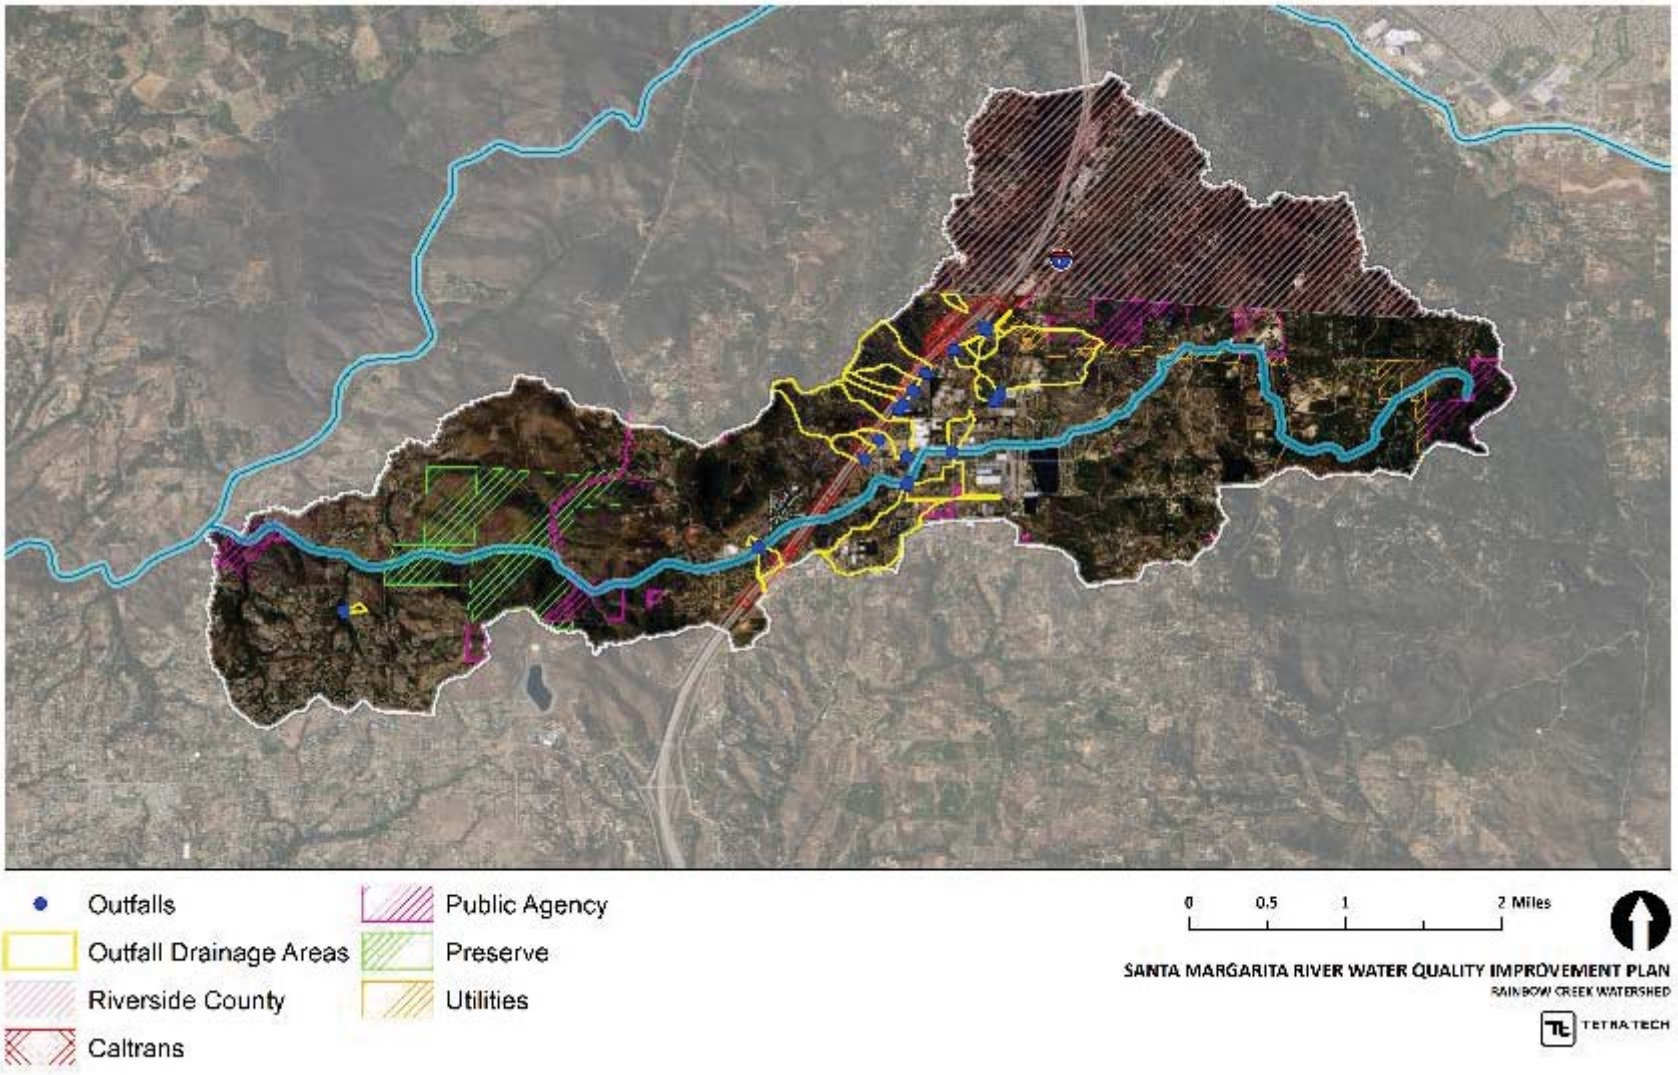

Figure 3-1. Overview of Rainbow Creek watershed strategy areas

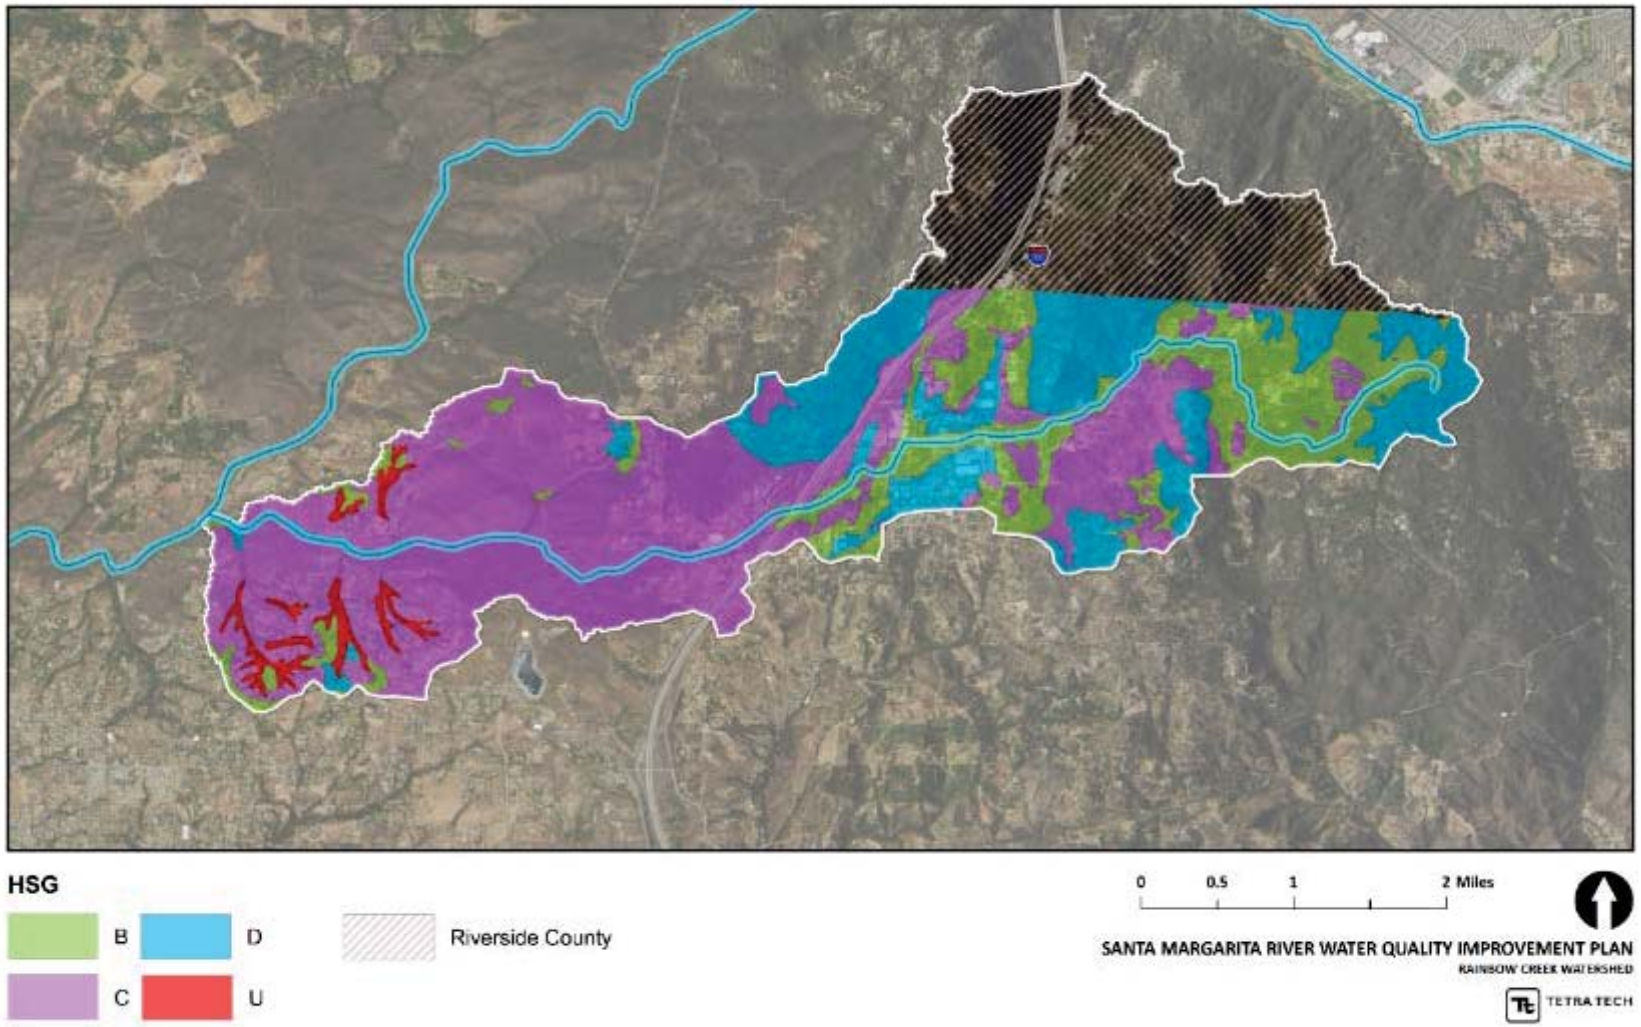

Figure 3-2. Hydrologic Soil Groups (HSG) in the San Diego County portion of Rainbow Creek watershed

3.1.2 Non-Structural Strategies

Non-structural strategies represent the first line of defense for management of stormwater pollutants. These institutional programs tend to be the most cost-effective options for water quality improvement because they focus on controlling the sources of pollution throughout the landscape before pollutants can be washed downstream by stormwater runoff. Maintenance and enhancement of non-structural strategies has been acknowledged by the San Diego Water Board to reduce pollutant loads by approximately 10% during development of previous WQIPs throughout the San Diego region (San Diego Regional Water Quality Control Board 2016b).

Non-structural strategies for Rainbow Creek should focus on source-control activities to reduce fertilizer runoff from private and public parcels (by means of enhanced education and enforcement; Figure 3-3), as well as channel maintenance to directly remove nutrient-laden sediment and organic matter. Together, these non-structural strategies were attributed a 10% reduction of TN and TP loading from the land surface (San Diego Regional Water Quality Control Board 2016b).

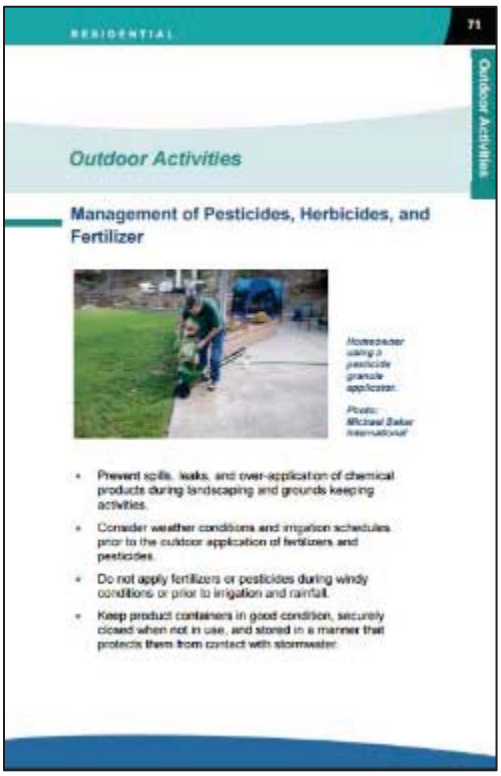

Figure 3-3. The County of San Diego has developed numerous pollution prevention education and outreach materials

The structural strategies proposed below were developed to supplement ongoing pollution prevention efforts. The NRMP outlines several waste control and cleaning practices for sources. Additionally, management practices for irrigation, nutrient control, and erosion and runoff are recommended for agricultural operations. The County's Department of Agriculture, Weights, and Measures (AWM) is authorized to respond to stormwater complaints and inspect commercial nurseries and greenhouse facilities to follow up that violations have been addressed and resolved.

3.1.3 Structural Strategies

Structural strategies are needed to assist with the reduction in nutrient loading to meet the requirements of the Rainbow Creek Nutrient TMDL. As described in the NRMP, these practices "serve to supplement source control and site design [best management practices]" (Michael Baker International 2016). The County of San Diego's Best Management Practice Design Manual (BMPDM) describes which structural strategies can be effective at targeting nutrient reduction, including vegetated filter strips, detention basins, wet ponds, and biofiltration (when designed with nutrient-sensitive media) (County of San Diego Department of Public Works 2016). An extensive body of peer-reviewed research agrees with the recommendations of the BMPDM, and also identifies stormwater wetlands, wetland swales, and stream restoration as effective nutrient management practices.

Given the constraints and conditions of the watershed discussed above in Section 3.1.1, nutrient-sensitive biofiltration was deemed the most appropriate strategy to address outfalls located upstream from Rainbow Creek; whereas, wetland channels are most appropriate for outfalls that discharge directly to Rainbow Creek and can be sited in the public right-of-way to intercept stormwater runoff. Stream restoration and near-channel improvements can also provide nutrient removal at a regional scale, albeit these projects would be located downstream of outfalls.

Table 3-1 provides a high-level summary of the recommended structural strategies. The following subsections describe additional details regarding nutrient removal mechanisms and model representation. Note that although the screening-level assessment deemed these appropriate strategies for this watershed, site-specific siting, sizing, and design specifications will be provided in the subsequent implementation plan.

Table 3-1. Summary of recommended structural strategies

	Recommended Structural Strategies		
	Nutrient-Sensitive Biofiltration	**Wetland Channels**	**Stream Restoration and Channel Improvements**
Type	Distributed	Distributed	Regional
Description	Shallow vegetated basins with engineered soil media and underdrains.	Vegetated areas that mimic natural physical and biological processes for capturing, storing, and treating runoff.	Augmentation or replacement of impacted habitat with equal or enhanced value to stream ecology.
Siting	At outfalls upgradient from receiving water	Along rights-of-way upstream from outfalls discharging to receiving water	Reaches of receiving water with impaired beneficial uses
Nutrient-Specific Design Components	Soil media must include minimal organic matter and residual nutrients. Underdrains should be upturned to create an anaerobic sump for denitrification	Saturated, anaerobic zones, dense vegetation, and long residence time should be provided to promote denitrification and phosphorus capture	Stream restoration should promote hyporheic exchanges and sediment capture.
Average Effluent Concentration or Efficiency	0.92 mg/L TN 0.089 mg/L TP	1.2 mg/L TN 0.092 mg/L TP	0.075 lb/yr TN and 0.068 lb/yr TP reduced per linear feet of restoration
References	Hunt et al., 2012; Leisenring et al., 2014; County of San Diego Department of Public Works 2014; County of San Diego Department of Public Works 2016	Caltrans 2010; Leisenring et al., 2014; CASQA 2003; Winston et al., 2012	Chesapeake Stormwater Network and Center for Watershed Protection 2014; County of San Diego Department of Public Works 2017

3.1.3.1 Nutrient-Sensitive Biofiltration

Nutrient-sensitive biofiltration is recommended to manage outfalls that are located upstream and do not directly discharge to Rainbow Creek because these areas tend to provide adequate relief to daylight the underdrain to the surface (preventing lengthy plumbing from the facilities to downstream conveyances). The Rainbow Creek watershed is conducive to biofiltration because soils have poor permeability and the groundwater table is generally shallow (which both tend to rule out infiltrating bioretention facilities).

Nutrient-sensitive biofiltration (BF-2 in the County BMP Design Handbook) applies principles of typical biofiltration BMPs by filtering stormwater through an engineered media, but the concept ensures that minimal fertilizer is applied to vegetation, includes very low concentrations of compost in soil media, and includes internal water storage (IWS) to promote a saturated, anaerobic zone for denitrification. Phosphorus is typically reduced via sediment capture and sorption to soil media. Vegetation within the basin can also uptake nutrients, although the intensity of uptake is not well understood. The IWS also enables a shallower invert depth such that the underdrain can be more easily tied into nearby infrastructure or daylighted to the ground surface. A typical cross section of biofiltration with IWS is shown in Figure 3-4 and photos are shown in **Figure 3-5**.

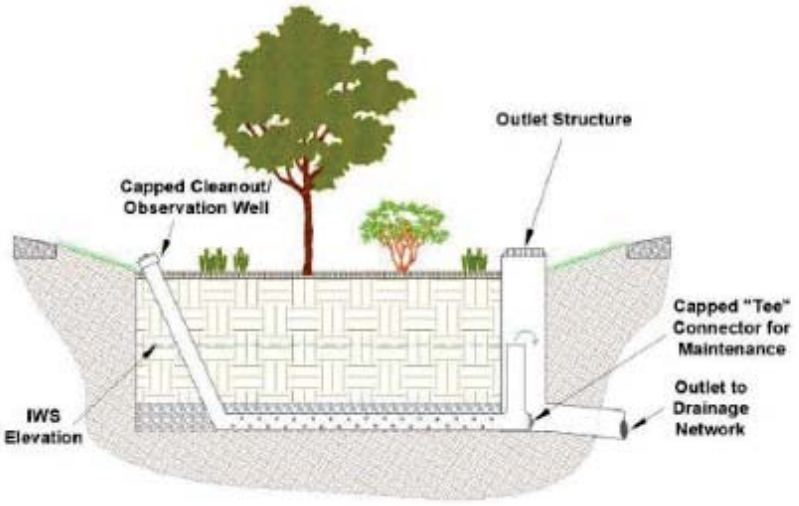

Figure 3-4. Typical biofiltration cross section, including IWS (from the San Diego County LID Handbook)

Figure 3-5. A biofiltration outlet structure showing upturned underdrains to create IWS (left) and biofiltration facility with cobbled surface cover in San Diego County (right). Source: Tetra Tech

3.1.3.2 Wetland Channel

Constructed wetlands have long been used to improve water quality. The Rainbow Creek watershed is well-suited for linear wetland channels (also known as wetland swales, wet swales, or vegetated rock filters depending on the design) along roadways because the high groundwater table will help sustain wetland vegetation and maintain saturated, anaerobic conditions for denitrification. The existing roadside ditches and concrete swales throughout the watershed could be retrofitted into constructed wetlands to capture nutrients while still conveying higher flows to Rainbow Creek.

Constructed wetlands function similar to biofiltration, in that they provide sedimentation, filtration, and biological transformations of pollutants; however, whereas biofiltration tends to provide *aerobic* soil near the ground surface to sustain upland vegetation, wetlands tend to maintain fully anaerobic soils to sustain wetland vegetation. System design can take on many forms depending on site constraints, including dividing the system into cells using baffles to control hydraulics and improve maintenance. To provide vector control, the systems can be designed such that captured stormwater flows laterally through subsurface gravel substrate and standing water is only present during wet weather (**Figure 3-6**). **Figure 3-7** shows example photographs of constructed wetland channels.

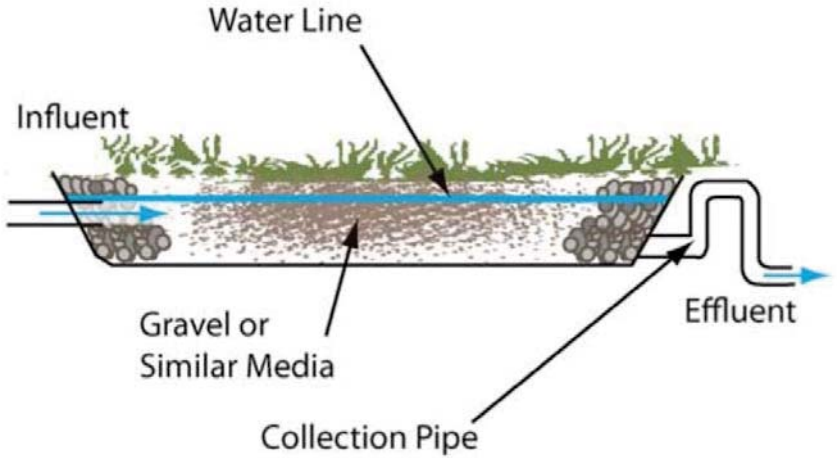

Figure 3-6. Example cross section of a subsurface gravel wetland for improved vector control (also called a vegetated rock filter) Source: Caltrans

Figure 3-7. A Southern California wetland channel (left) and a roadside wetland swale. Source: Tetra Tech

3.1.3.3 Stream Restoration and Channel Improvements

Rainbow Creek and its tributaries have been heavily impacted and degraded by development, including the removal of riparian vegetation and channelization of the creek. Stream restoration can be an effective strategy to help restore beneficial uses to degraded creeks and enhance nutrient capture and assimilation. Typical restoration projects include reshaping of the channel, installation of features to enhance fluvial processes, and replanting of riparian vegetation. For nutrient management, it is particularly important that the project attempt to restore the exchange of water in the hyporheic zone (the interface between surface water and groundwater in the bed of the channel, as shown in **Figure 3-8**) and include design elements to trap and immobilize sediment-born phosphorus. Projects can also include near-channel improvements to provide additional water quality and hydraulic benefits, such as construction of offline wetlands and basins to mimic historical floodplain functions.

Stream restoration is an accepted strategy for nutrient management in the Chesapeake Bay watershed, where an expert panel has developed a guidance document for attributing nutrient load reductions to restoration projects (Chesapeake Stormwater Network and Center for Watershed Protection 2014). Planning-level studies in Southern California substantiate the potential for stream restoration and near-channel features to provide comprehensive pollutant removal benefits (San Diego County 2017). While this strategy is inherently applied downstream from the outfall, the strategy strives to directly restore the beneficial uses of the receiving water while simultaneously reducing nutrient loads contributed by the outfall.

Figure 3-9. Example photographs of a stream in a nutrient-sensitive watershed before (left) and after (right) restoration.

3.2 COMPLIANCE APPROACH

The goal of the WQIP is to demonstrate compliance with the MS4 Permit; therefore, the modeling approach first prioritized upstream strategies to address loads originating from outfalls (19 total in the watershed), then evaluated downstream strategies to address remaining excess loads contributed by other remaining areas. This approach provides permittees and regulators with information useful for decision making at the watershed-scale. The strategies discussed in the previous section were evaluated and customized to the conditions and scale of the treated areas so that cost-effective and actionable solutions could be recommended.

Consistent with other San Diego region WQIPs (San Diego Regional Water Quality Control Board 2016b), the compliance analysis was conducted using a customized version of EPA's System for Urban Stormwater Treatment and Analysis INtegration (SUSTAIN) to simulate long-term surface runoff capture and nutrient load reduction by strategies. Simulations were driven by the same baseline HSPF land surface loading data used to calculate the numeric targets. The customized version of SUSTAIN enabled simulation of average effluent concentrations from structural strategies to better represent water quality performance. In lieu of a one-size-fits-all sizing approach (which could result in overspending), SUSTAIN's optimization algorithms were used to guide selection of the level of implementation with the least cost to achieve the targets. Areas were optimized sequentially to prioritize upstream treatment. **Figure 3-10** depicts example results from the optimization process for one outfall; the chart shows how the most efficient green infrastructure size for TN reduction was selected from the cost-effectiveness curve. Despite the need for higher relative reductions of TP, the optimization was driven by TN load reduction because green infrastructure is more efficient at removing TP than TN. In other words, TN was considered the "limiting" pollutant for green infrastructure sizing.

The design of distributed green infrastructure was optimized with respect to the drainage area associated with each outfall selected for treatment resulting in cost-effective sizing recommendations for all outfall catchment areas. Once the optimum green infrastructure sizes were identified for the outfall areas, the analysis shifted to downstream opportunities. The compliance approach is shown conceptually in **Figure 3-11**.

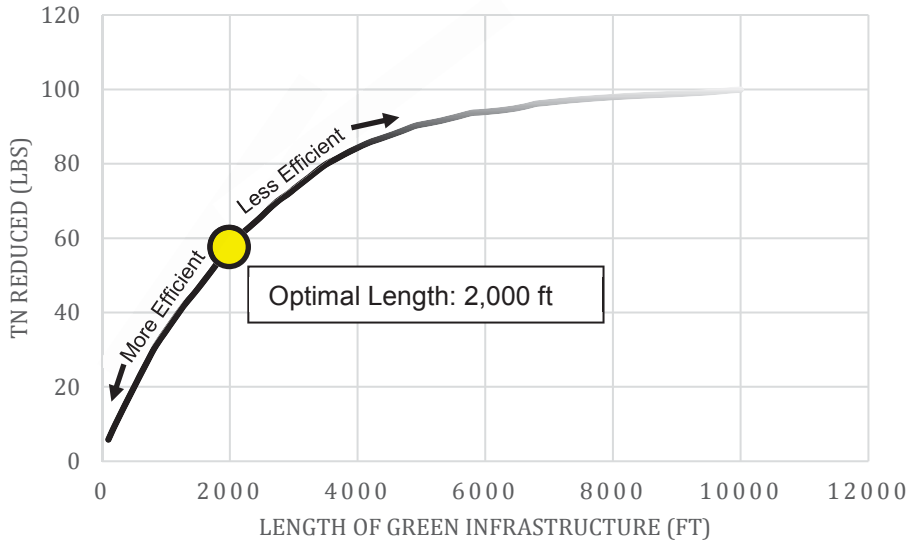

Figure 3-10. Example cost-effectiveness curve used to identify optimum sizing for one of the outfalls

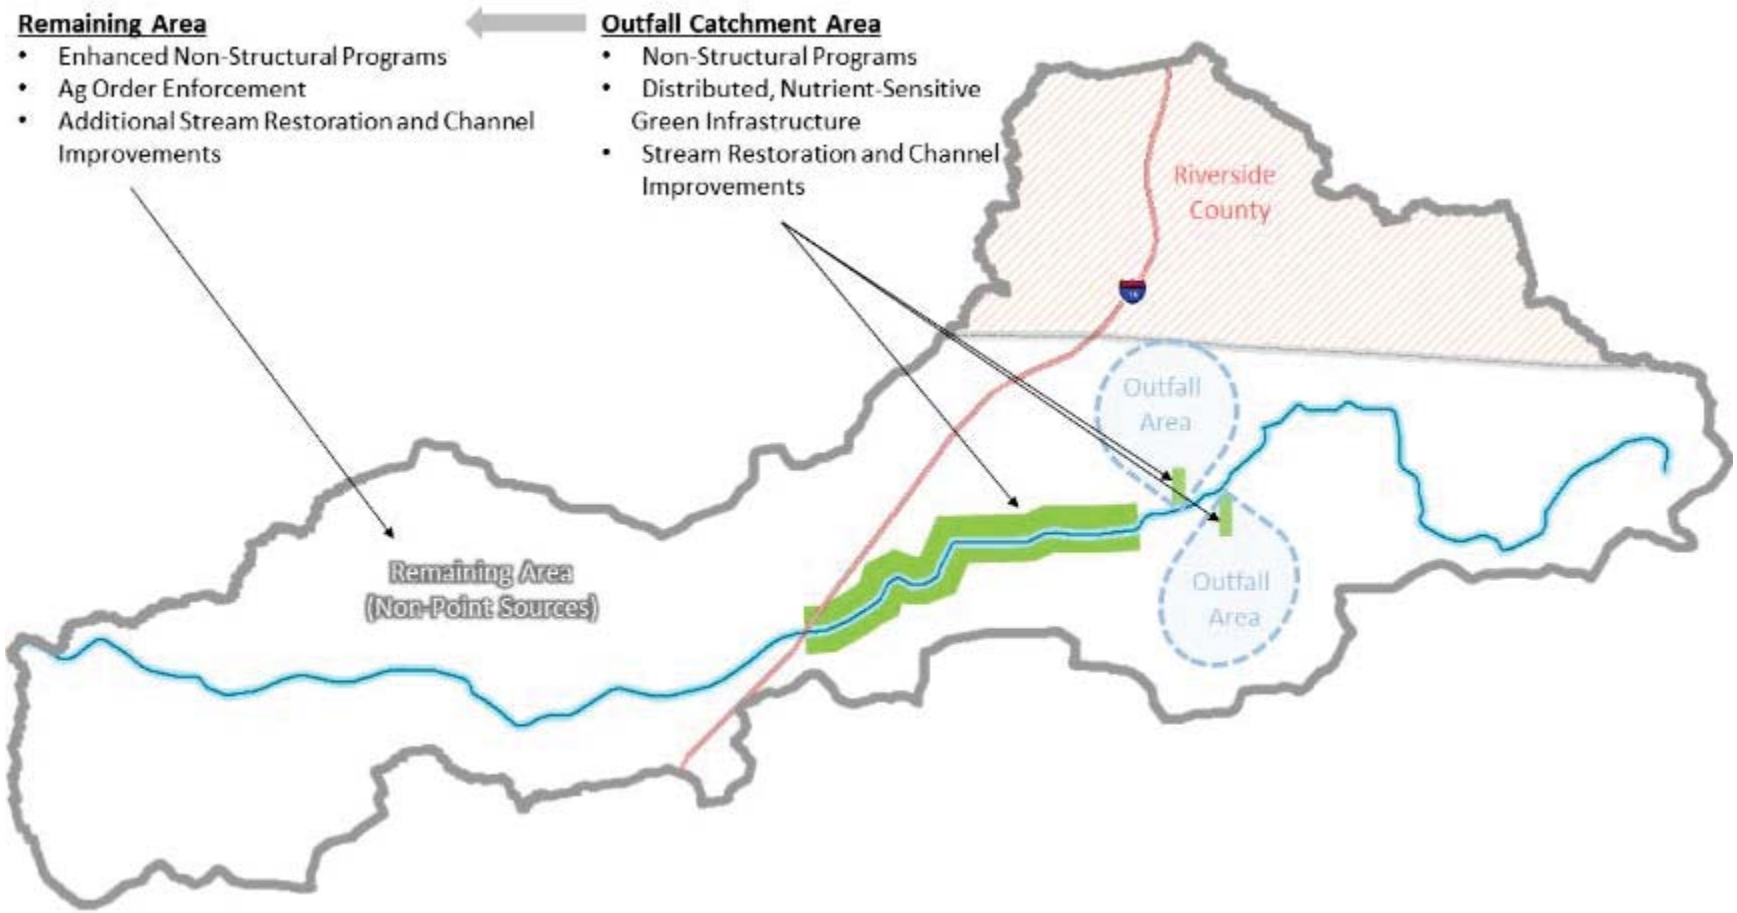

Figure 3-11. Conceptual figure showing modeling approach.

3.3 COMPLIANCE ANALYSIS RESULTS AND RECOMMENDATIONS

Treatment of the top 6 priority outfalls was targeted in the compliance analysis to support a cost-effective strategy, as discussed below. Furthermore, green infrastructure was optimized for load reduction at the outfall scale.

To demonstrate compliance, the following methodology was used to distribute the load reduction "credit":

1. Load reductions achieved by County-implemented non-structural programs and distributed green infrastructure were first attributed.
2. Stream restoration and channel improvements were then sized to capture the remaining targeted at-source loading.

Note that the recommended strategies below exceed the total load reduction targets for TP because the strategies are more efficient for TP capture. In other words, TN was the "limiting pollutant" despite TP having a higher relative reduction target in **Table 2-8**.

Table 3-2. Modeled Load Captured to Meet Compliance

Compliance Area	Strategy	Modeled TN Captured (lb/yr)	Modeled TP Captured (lb/yr)
Six Priority Outfalls	Non-Structural Programs	56	26
	Distributed Green Infrastructure or equivalent (Treating 6 Priority Outfalls)	150	96
	Stream Restoration and Channel Improvements or equivalent (Public-Private Partnerships)	161	156
	Subtotal	**367**	**278**
Stream	Stream Restoration	3,808	1,980
	Total	**4,175 (Target = 4,175)**	**2,258 (Target = 2,221)**

Table 3-3 shows the modeled nutrient reduction achieved with green infrastructure installed at every outfall, as well as installed only at the outfalls with the top 6 nutrient loadings (**Figure 3-13**), which comprise 77% of the total loading from all 19 outfalls. These 6 outfalls were prioritized for green infrastructure implementation to address nutrient loading from outfall catchment areas (as shown in **Figure 3-11**). Focusing on the top 6 outfalls contributing the largest nutrient loads significantly saves mobilization costs, relative to installing green infrastructure at every outfall that would result in only small additional load reductions (**Figure 3-12**). The remaining reduction requirements will be addressed through stream restoration.

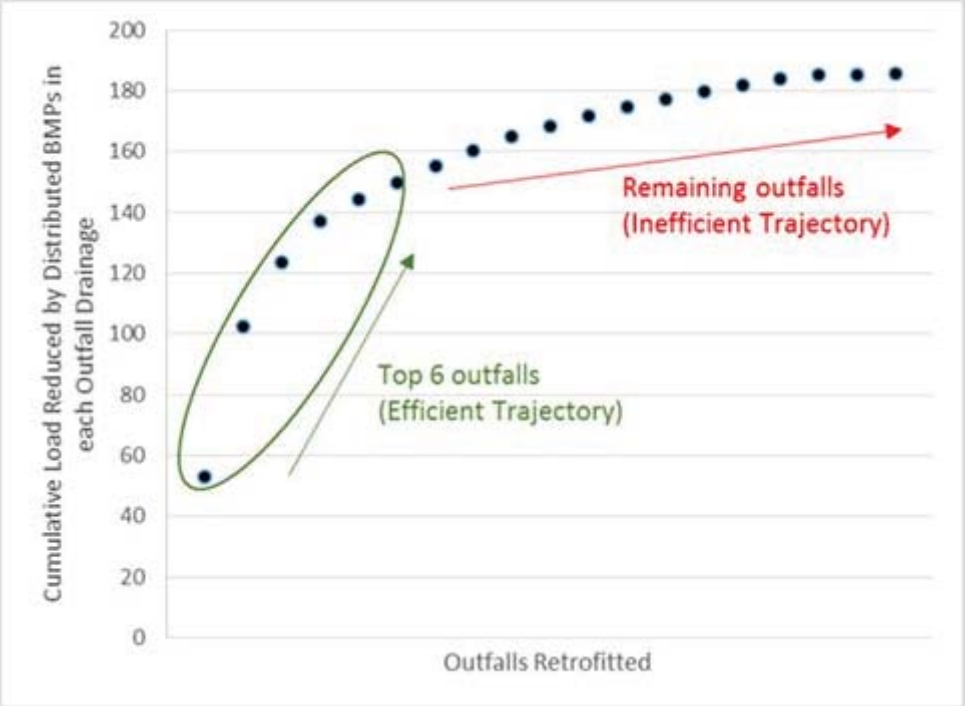

Figure 3-12. Cumulative load reduced by distributed BMPs, based on the number of outfalls retrofitted.

Table 3-3. Modeled Reduction from All Outfalls Compared with Prioritization of the Top 6 Outfalls

Outfall Extent	Optimum GI Area: Drainage Area Ratio [1]	TN				
		Outfall Target Reduction (lb)	Non-Structural Reduction (lb)	Reduction from Green Infrastructure (lb)	Total Reduction (lb)	% of Outfall Target Achieved
All Outfalls	0.267%	367	56	186	242	65.9%
Top 6 Outfalls	0.183%			150	206	56.1%

Outfall Extent	Optimum GI Area: Drainage Area Ratio [i]	TP				
		Outfall Target Reduction (lb)	Non-Structural Reduction (lb)	Reduction from Green Infrastructure (lb)	Total Reduction (lb)	% of Outfall Target Achieved
All Outfalls	0.267%	241	26	120	146	60.6%
Top 6 Outfalls	0.183%			96	122	50.6%

[1] Aggregate of all green infrastructure area over total outfall drainage area

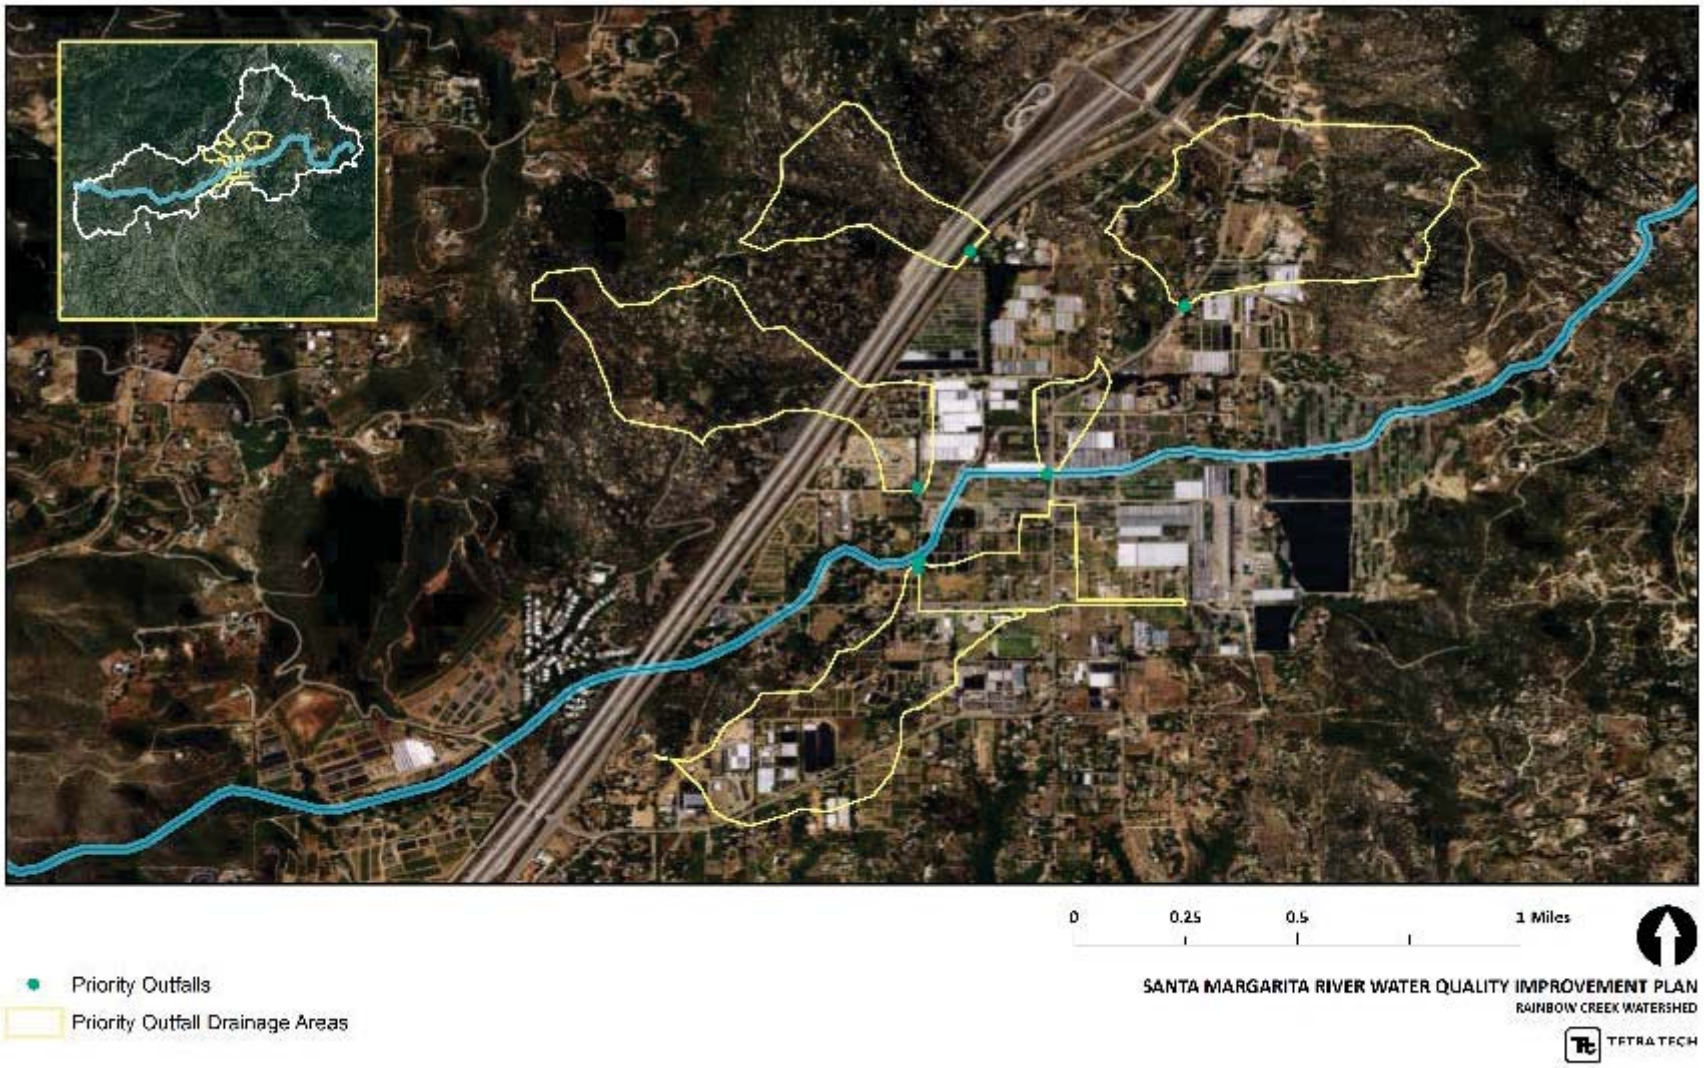

Figure 3-13. Outfalls Prioritized for Distributed Green Infrastructure

The modeling results indicate that a substantial portion of the nutrient loading from outfall catchment areas can be captured by strategically applying distributed green infrastructure at the outfalls. Stream restoration downstream of the outfall catchment areas can thus be sized primarily to capture the remaining at-source loading from these areas not captured by the distributed green infrastructure at the outfalls.

Table 3-2 lists the recommended strategies to manage excess loads based on the results of the compliance analysis. Note that these estimates will be updated during the adaptive management process. **Table 3-4** proposes the strategies needed to meet the TMDL compliance requirements of Attachment E.3, Table 3.3 of the MS4 Permit (San Diego Regional Water Quality Control Board 2015).

Table 3-4. Proposed Structural Strategies to Meet Compliance with Rainbow Creek TMDL

Strategy	Quantity[1]	Units	Scheduled Compliance
Nutrient-Sensitive Biofiltration (Based on six priority outfalls) or equivalent	0.21	acres	12/31/21
Wetland Channels (Based on six priority outfalls) or equivalent	0.39	acres	12/31/21
Stream Restoration and Channel Improvements or equivalent (Public-Private Partnerships)	2,143 [2]	linear feet	12/31/21

1. Note that quantities are based on planning-level, desktop analyses. Actual quantities will vary during implementation on the basis of site-specific designs, conditions, and constraints.
2. Sized based on rate of 0.075 lbs/ft/yr removed of TN (Chesapeake Stormwater Network and Center for Watershed Protection 2014)

1 Introduction

1.1 Background

On May 8, 2013 the California Regional Water Quality Control Board, San Diego Region (San Diego Water Board) adopted Order No. R9-2013-0001; NPDES No. CAS 0109266, National Pollutant Discharge Elimination System (NPDES) Permit and Waste Discharge Requirements for Discharges from the Municipal Separate Storm Sewer Systems (MS4s) Draining the Watersheds within the San Diego Region (Regional MS4 Permit). Order No. R9-2015-0001 extended the permit to Orange County Region 9 Co-Permittees on February 11, 2015 and Order No. R9-2015-0100 extended the permit to Riverside County Region 9 Co-Permittees. The Regional MS4 Permit, which became effective on June 27, 2013, replaces the previous MS4 Permits that covered portions of the Counties of San Diego, Orange, and Riverside within the San Diego Region. There were two main goals for the Regional MS4 Permit:

- To have more consistent implementation, as well as improve inter-agency communication (particularly in the case of watersheds that cross jurisdictional boundaries), and minimize resources spent on the permit renewal process.
- To establish requirements that focused on the achievement of water quality improvement goals and outcomes rather than completing specific actions, thereby giving the Co-Permittees more control over how their water quality programs are implemented.

To achieve the second goal, the Regional MS4 Permit requires that a Water Quality Improvement Plan (WQIP) be developed for each Watershed Management Area (WMA) within the San Diego Region. As part of the development of WQIPs, the Regional MS4 Permit provides Co-Permittees an option to perform a Watershed Management Area Analysis (WMAA) through which watershed-specific requirements for structural BMP implementation for Priority Development Projects can be developed for each WMA. This report presents the Co-Permittees' approach and results for the regional elements of the WMAA developed for the Santa Margarita River within the San Diego County area and the results of additional analysis that was developed for the Middle and Upper Santa Margarita River Watershed within the Riverside County area.

This Santa Margarita WMAA builds upon the work completed in the 2015 San Diego County Regional WMAA (Geosyntec Consultants and Rick Engineering Company, 2015). The regional analysis developed the tools for the Santa Margarita Region (SMR) Watershed Management Area (WMA) and began the mapping effort in the lower SMR. Figure 1-1 shows and overall map of the SMR. San Diego County's mapping elements can be found in the 2015 San Diego County Regional WMAA located in Attachment I.

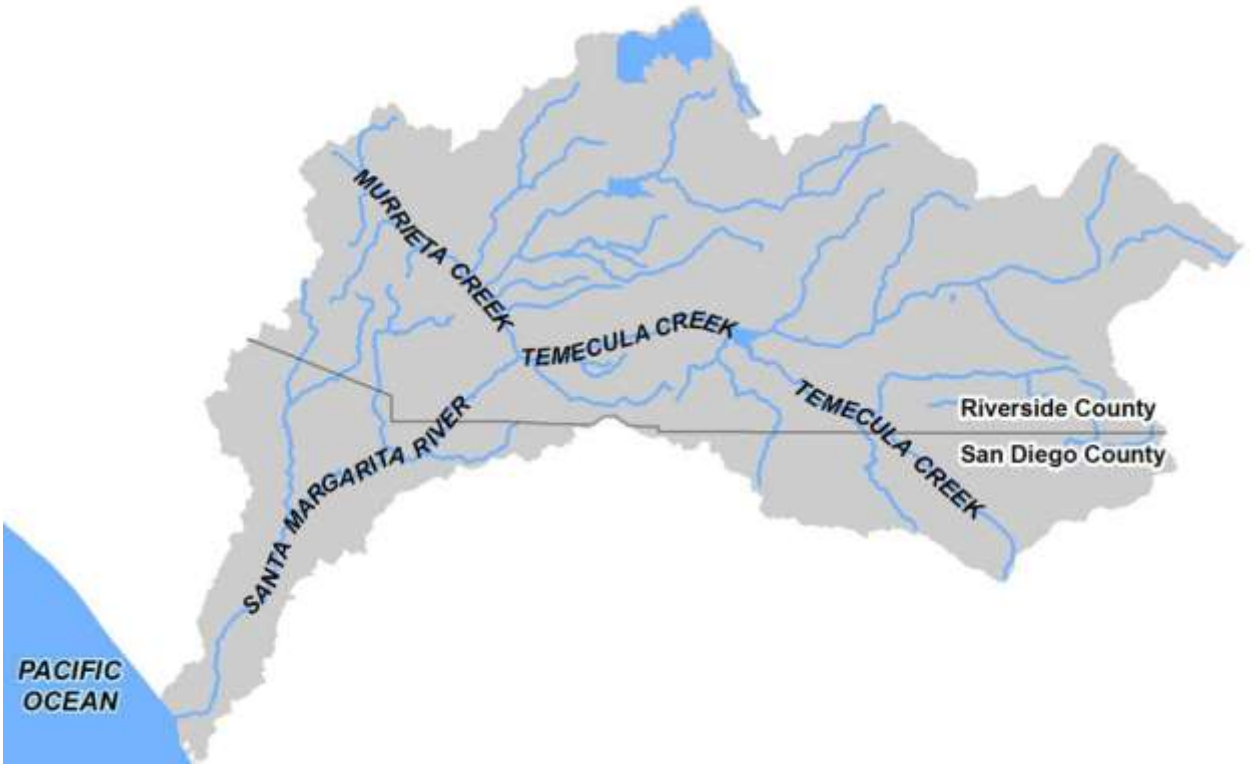

Figure 1-1. Santa Margarita River Watershed Management Area

1.2 Watershed Management Area Analysis

The Regional MS4 Permit, through inclusion of the WMAA, provides an optional pathway for Co-Permittees to develop an integrated approach for their land development programs by promoting evaluation of multiple strategies for water quality improvement and development of watershed-scale solutions for improving overall water quality in the watershed. The WMAA comprises the following three components as indicated in the Regional MS4 Permit:

- Perform analysis and develop Geographic Information System (GIS) layers (maps) by gathering information pertaining to the physical characteristics of the WMA (referred to herein as WMA Characterization). This includes, for example, identifying potential areas of coarse sediment supply, present and anticipated future land uses, and locations of physical structures within receiving streams and upland areas that affect the watershed hydrology (such as bridges, culverts, and flood management basins).
- Additionally, using the WMA Characterization maps, identify areas within the watershed management area where it is appropriate to allow for exemptions from hydromodification management requirements that are in addition to those already allowed by the Regional MS4 Permit for Priority Development Projects (PDP). The Co-Permittees shall identify such cases on a watershed basis and include them in the WMAA with supporting rationale to support claims for exemptions.
- Using the WMA Characterization results, compile a list of candidate projects that could potentially be used as alternative compliance options for Priority Development Projects.

Priority Development Projects (PDPs), at the discretion of the Co-Permittees, may participate in an alternative compliance program to provide greater overall water quality benefit to the watershed management area and offset Stormwater Pollutant Control Impacts and Hydromodification Control Impacts associated with the PDP. A PDP may be allowed to utilize alternative compliance in lieu of complying with the storm water pollutant control BMP performance requirements. The PDP must mitigate for the portion of the pollutant load in the design capture volume not retained onsite. If a PDP can utilize alternative compliance, flow-thru treatment control BMPs must be implemented to treat the portion of the design capture volume that is not reliably retained onsite.

For projects to participate in an Alternative Compliance Program, the WQIP must include the optional WMAA; and Water Quality Equivalency calculations must have been accepted by the San Diego Water Board's Executive Officer. The San Diego Water Board accepted the Water Quality Equivalency Guidance Document in December 2015. Furthermore, a fee structure program is required to complete the Alternative Compliance Program.

On December 17, 2015 the California Regional Water Quality Control Board accepted the Water Quality Equivalency Guidance Document and Water Quality Equivalency Automated Calculation Worksheets (WQE Guidance Documents). The effective date of the WQE Guidance Documents is the date of the acceptance letter and serves as the single, region-wide, applicable date after which Co-Permittee-approved alternative compliance projects may begin generating credits for potential future banking, tracking, trading, and selling. The WQE Guidance Documents form the regional and technical basis to determine the water quality benefits associated with BMPs implemented as part of an alternative compliance program. Since approval of the WQE Guidance documents, the Co-Permittees have convened a Technical Advisory Group of regional stakeholders to develop a credit framework for facilitating the use of alternative compliance in those jurisdictions. The current status of the credit framework is as follows:

1. Technical working group was established in 2016 to develop an Alternative Compliance Program for the subregion and gather input from Co-Permittees and the private sector.
2. Western Riverside Council of Governments (WRCOG) met with San Diego Regional Water Quality Control Board in August 2017 to introduce the technical working group, its findings, and plan to develop program.
3. Technical working group has developed a Draft Credit System Policy Manual handbook that will provide details on eligible project type, credits, credit eligibility, bank, and roles.
4. WRCOG has sent a request to Regional Board staff to present program and details to San Diego Regional Water Quality Control Board and acquire feedback.

1.3 Scope of Work for Regional WMAA and Middle and Upper Santa Margarita River Watershed (within Riverside County)

In July 2013, the Co-Permittees elected to fund a regional effort to develop elements of the regional WMAA for the nine San Diego-area WMAs within the County of San Diego that are currently subject to the Regional MS4 Permit, which include:

- Santa Margarita River (for portion in San Diego County)

- San Luis Rey River
- Carlsbad
- San Dieguito River
- Los Peñasquitos
- Mission Bay & La Jolla Watershed
- San Diego River
- San Diego Bay
- Tijuana River (for portion in San Diego County)

The regional-level information developed is intended to provide consistency across WMAs and serve as the foundation for developing watershed-specific information for each WMA to be developed through the WQIP process. The regional effort excluded the middle and upper portion of the Santa Margarita Watershed within Riverside County. Therefore, the scope of this WMAA will combine watershed specific information from the regional effort with additional studies performed on the Middle and Upper Santa Margarita Watershed within Riverside County. The regional WMAA will be used as a guide for developing information within Riverside County. This effort included:

- Development of GIS map layers that characterize the WMA using data previously collected, readily available, and provided by the Co-permittees, including:
- Description of dominant hydrologic processes, such as areas where infiltration or overland flow likely dominates;
- Description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral;
- Current and anticipated future land uses;
- Potential coarse sediment yield areas;
- Locations of existing flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins;
- Development of a list of candidate projects for an optional alternative compliance program; and
- Development of additional criteria and analyses to support proposed exemptions that were originally developed in the approved 2013 Santa Margarita Region Hydromodification Management Plan.

The scope of work for the Middle and Upper Santa Margarita Watershed effort and the regional effort within San Diego County excluded performing analysis within the following areas unless data was readily available, as Co-Permittees do not have jurisdiction over these areas:

1. State Lands;
2. U.S. Departments of Defense land;
3. U.S. National Forest land;
4. U.S. Department of Interior land; and
5. Tribal lands.

1.4 Report Organization

This report references the regional WMAA for San Diego County for the Lower Santa Margarita River Watershed within San Diego County. Additional supporting information has been developed for the Middle and Upper Santa Margarita River Watershed to supplement the regional WMAA and provide a complete data set that covers the entire Santa Margarita River WMA. This report is organized as follows:

- Chapter 1 provides the project background and purpose.
- Chapter 2 describes the technical basis for characterizing the WMA.
- Chapter 3 describes potential candidate projects for the Middle and Lower Santa Margarita Watershed.
- Chapter 4 summarizes the analyses performed to support reinstating select exemptions from hydromodification control requirements for PDPs.
- Chapter 5 presents the WMAA conclusions.
- Chapter 6 presents the references used for the WMAA.
- Chapter 6 presents the Glossary used for the WMAA.
- Attachments A-F presents the exhibits for watershed management area characterization within the Santa Margarita River Watershed.
- Attachment G presents the supporting information for Hydrologic Response Unit and Critical Course Sediment Yield Analysis for the Middle and Upper Santa Margarita Watershed within Riverside County.
- Attachment H presents the supporting information for Hydromodification Exemptions on Santa Margarita Rivers and Murrieta Creek.
- Attachment I provides the San Diego County Regional Watershed Management Area Analysis.
- Attachment J presents the Candidate Projects for the Middle Santa Margarita Subwatershed.

Table 1.1 summarizes the Permit sections that identify specific WMAA requirements and the corresponding sections in this WMAA that comply with the Permit.

Table 1-1. WMAA corresponding Permit requirements

2 Watershed Management Area Characterization

2.1 Dominant Hydrologic Processes

The Regional MS4 Permit requires that the WMAA include a description of dominant hydrologic processes, such as areas where groundwater recharge, interflow, or overland flow likely dominate (San Diego RWQCB, 2015). Figure 2-1 displays the screening level analysis used to define the hydrologic response unit (HRU) and to then associate the HRU to a final dominant hydrologic process endpoint (e.g., overland flow; interflow; or groundwater recharge). The evaluation of dominant hydrologic processes in the SMR, however, should also consider evapotranspiration (ET). ET is the quantity of water transpired by plants, retained in plant tissues, and evaporated from plant tissues and surrounding soil surfaces (Department of Water Resources, 2005). A comparison of the estimated mean annual precipitation (4 – 10 inches) with the estimated fraction of precipitation lost to ET (90 – 99%) over a thirty year timespan in the Riverside-area watersheds suggests that ET is the dominant hydrologic process (Sanford and Selnick, 2013). Therefore, theoretically, if all the annual precipitation for Riverside County watersheds remained stationary where it fell and did not infiltrate or flow downstream to receiving waterbodies, then the precipitation would be loss to ET. Rain events, however, do not remain stationary and often produce runoff in these watersheds, especially in the urbanized areas, where the topography and land cover tend to accelerate the runoff rate downstream. Furthermore, this analysis focuses on developing information and mapping to gain an understanding of the macro-scale opportunities for locating projects that take advantage of either capturing overland flow for treatment or for supplementing the groundwater regime. Therefore, this analysis is based on the methodology illustrated in Figure 2-1 and described in Technical Report 605 titled *Hydromodification Screening Tools: GIS-Based Catchment Analyses of Potential Changes in Runoff and Sediment Discharge* (Booth et al. 2010). After considering the effects of ET (see Section 2.1.4), and an intermediate category of infiltration, the predicted fate of runoff within the Santa Margarita watershed management area was evaluated based on the hydrologic process endpoints - overland flow, interflow, or groundwater recharge.

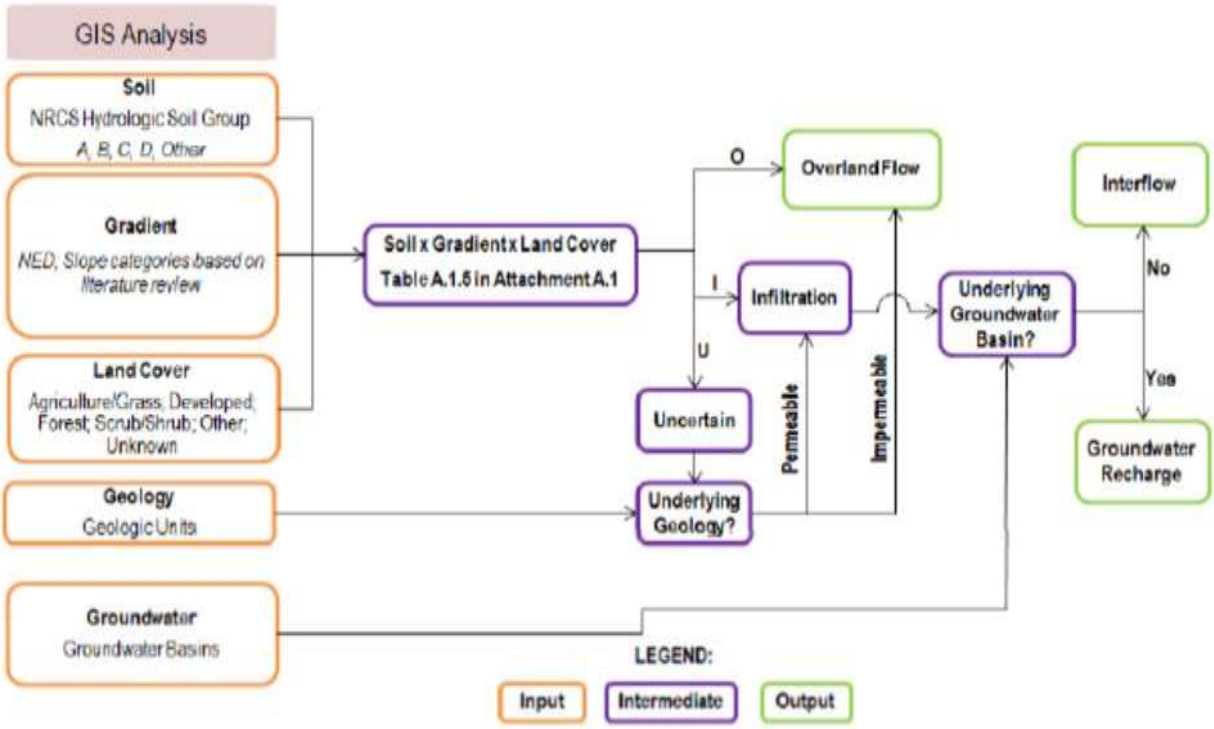

Figure 2-1. Hydrologic Response Unit and Hydrologic Process Flow Chart

2.1.1 Hydrologic Response Unit

The hydrologic process endpoint (e.g., overland flow, interflow, or groundwater recharge) was derived by first integrating soil, gradient, and land cover datasets into hydrologic response units (HRUs) using a geographic information system (GIS). HRUs are regions within a watershed which are presumed to have similar hydrologic attributes based on the combination of soil, gradient, and land cover. The GIS data acquired from public-domain sources are listed in Table 2.1.

Table 2-1. Hydrologic Response Unit Data Types and Source

Soil Categories

Soil categories were based on United States Department of Agriculture/National Resources Conservation Service (USDA/NRCS) Hydrologic Soil Group (HSG) classifications, which are commonly used to describe runoff/infiltration potential of soils on a regional scale. There are four HSGs: A, B, C, and D and three dual groups: A/D, B/D and C/D. HSGs are based on the rate of water infiltration, with Group A having the highest rates and Group D having the lowest rates. In the dual groups, the first letter is for drained areas and the second letter is for undrained areas. The following describes the methodology used to assign a single HSG rating for each of the dual groups identified in the Middle and Upper SMR Watershed.

Over two hundred polygons, equating to an area of approximately 7,000 acres in the Riverside County portion of the SMR WMA GIS were rated with a dual HSG. Dual HSG ratings were evaluated based on the mapped geologic unit as determined by published geologic mapping information, a desktop evaluation, and soils laboratory results. Specifically, the mapped geologic units were compiled into similar categories and then referenced with a geologic unit name. Geologic units were then categorized as either "coarse" or "fine" based on typical weathering characteristics for the bedrock unit or primary grain size of the sedimentary unit. For example, some geologic units weather to a coarse material such as silty sand and were therefore classified as "coarse". Geologic units that weather to a sandy clay were classified as "fine". Regarding sedimentary formations that are usually associated with variable amounts of coarse and fine units, the final classification was based on the predominating composition, i.e., sandstone/silty sand versus claystone. Finally, given that silty sands drain very quickly, any geologic unit identified as coarse was considered drained and was identified as either HSG A, B, or C. Whereas, geologic units classified as "fine" were considered undrained and were rated as HSG D in the GIS database.

HSG data were not available for some of the areas of the SMR WMA. These areas are designated as Uncertain (U) in the GIS. For HRUs considered uncertain (U), the underlying regional geology was used to evaluate whether overland flow or infiltration were dominant. This analysis was performed using GIS and is discussed further in Section 2.1.5.

Gradient Categories

The hillslope digital elevation model (DEM) for San Diego County and Riverside County was analyzed to produce a grid of slope values, which were subsequently classified into discrete categories: 0 - 2%; 2 - 6%; 6 - 10%; and greater than 10%. The greater than 10% slope category was considered the maximum limit given that slopes steeper than 10% are assumed to be dominated by overland flow. This limit is also consistent with Technical Report 605 (Booth et al. 2010).

Land Cover

Land cover categories for the Riverside County portion of the Santa Margarita WMA were defined using the ecology vegetation GIS map layers developed for Western Riverside County in the SMR (Riverside County GIS, 2014). For the San Diego County portion of the Santa Margarita watershed management area, land cover categories were defined using the Ecology Vegetation GIS map layer developed for the City of San Diego, the County of San Diego and SANDAG. This GIS map layer was downloaded from SanGIS (2013). The vegetation categories in the GIS layers were grouped to match the following land cover categories: Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other and Other (Water) (see Tables A.1 and A.2, Attachment A). Land cover categories for Agriculture/Grass, Forest, Scrub/Shrub, Unknown Other and Other (Water) were then related to land use categories using Table A.3 in Attachment A. A land use category for the Developed land cover category was not determined because this land cover was assumed to have overland flow as its dominant hydrologic endpoint. Table A.4 in Attachment A displays the results showing how the land cover categories related to land use.

2.1.2 Geology and Groundwater Basins

As indicated in Figure 2-1, the intermediate process is implemented after the HRUs are defined. This process entails identifying the geologic units and groundwater basins in the Santa Margarita WMA. The GIS data acquired from public-domain sources for identifying geologic units and groundwater basins are listed in Table 2.2.

Table 2-2. Geologic Unit and Groundwater Basin Data Type and Source

GIS	Dataset	Source	Year	Description

Geologic Unit

The geology layer was categorized based on rock types, the predominant sediment size generated upon erosion, and their associated erodibility (Booth, et al., 2010). The attribution (and thus the naming) of the geology classes included the following categories:

- Coarse Bedrock (CB):
- Coarse Sedimentary Impermeable (CSI):
- Coarse Sedimentary Permeable (CSP):
- Fine Bedrock (FB):
- Fine Sedimentary Impermeable (FSI):
- Fine Sedimentary Permeable (FSP): and
- Other (O).

The underlying geology was then evaluated to determine if it was permeable or impermeable. This determination was based on a desktop evaluation using the best professional judgment of a Certified Engineering Geologist. All geologic units identified as permeable were considered to have infiltration as the hydrologic process endpoint, whereas all impermeable layers were considered to have overland flow as the hydrologic process endpoint. The Certified Engineering Geologist also performed a desktop evaluation of any HRUs that were identified as uncertain. Again, if the underlying geology was considered permeable, then these uncertain areas were presumed to be dominated by infiltration. Likewise, if the underlying geology was considered impermeable, then these uncertain areas were categorized as overland flow.

2.1.3 Groundwater Basins

For HRUs with relatively high infiltration the presence or absence of a regional groundwater basin underlying these areas determined whether the dominant hydrologic process was designated as interflow or groundwater recharge. The groundwater recharge hydrologic process was assigned as dominant for those applicable areas which have an underlying groundwater basin. The interflow hydrologic process was assigned as dominant for those applicable areas which did not have an underlying groundwater basin.

2.1.4 Hydrologic Characteristics and Evapotranspiration (ET)

For each of the land cover/land use categories the ratio of precipitation lost to evapotranspiration (i.e. an evapotranspiration coefficient) was estimated using the process described by Geosyntec Consultants and Rick Engineering Company (2015) as indicated below as Equation 1 (Eq 1). Since precipitation is the sum of the resulting runoff, infiltration, and evapotranspiration, the coefficients for these three hydrologic pathways sum to one using Equation (Eq) 1.

Runoff Coefficient + Infiltration Coefficient + Evapotranspiration Coefficient = 1 (Eq. 1)

2.1.4.1 Evapotranspiration Estimate

To estimate the evapotranspiration (ET) coefficient for each land cover, the runoff coefficient was identified by evaluating the highest runoff potential for the most common storm conditions. Using this, the ET coefficient was calculated as the difference (i.e., ET Coefficient = 1 – Runoff Coefficient). The ET coefficient calculated for the highest runoff potential was then applied to all soil types and slopes within each land use category.

2.1.4.2 Infiltration Estimate

The infiltration coefficient for each applicable HRU (i.e., combination of soil, gradient, and land cover) was estimated by subtracting both the runoff coefficient, and the ET coefficient, from one (i.e., Infiltration Coefficient = 1 – Runoff Coefficient – ET Coefficient).

2.1.4.3 Runoff Estimate

For each applicable HRU, the runoff coefficient was divided by the infiltration coefficient to obtain a ratio representing the potential for runoff or infiltration. The higher the ratio, the greater the potential for runoff to be a more dominant hydrologic process than infiltration. Similarly, the lower the ratio, the greater the potential for infiltration to be a more dominant hydrologic process than runoff.

2.1.4.3.1 Associate Runoff and Infiltration HRUs

The following designations were assigned to each applicable HRU based on the runoff to infiltration ratio (i.e., runoff coefficient/infiltration coefficient). These designations were based on best engineering judgment with the underlying assumption that if a runoff or infiltration coefficient is more than 50% greater than its counterpart, then the prevailing process is considered dominant. Table A.5 in Attachment A summarizes these findings for Riverside County and San Diego County.

- HRUs with runoff to infiltration ratios greater than 1.5 (3:2 ratio) were assumed to have relatively high runoff and overland flow was considered its dominant hydrologic process. These HRUs are designated by the letter "O" (Overland flow is dominant process).

- HRUs with runoff to infiltration ratios less than 0.67 (2:3 ratio) were assumed to have relatively high infiltration and its dominant hydrologic process was either interflow or groundwater recharge, based on analysis described in subsequent steps. These HRUs are designated by the letter "I" (Interflow is dominant process) in Table A.5 of Attachment A.
- For HRUs with runoff to infiltration ratios ranging from 0.67 to 1.5, it was uncertain whether it was dominated by overland flow or infiltration. These HRUs are designated by the letter "U" (Dominant process is uncertain).
- For HRUs that have a Developed land cover or a gradient greater than 10%, the runoff to infiltration ratios were not calculated because these HRUs were assumed to have overland flow as the dominant hydrologic process. These HRUs are designated by the letter "O" (Overland flow is dominant process).

2.1.5 Uncertain HRUs

For HRUs considered uncertain (U), the underlying regional geology (Kennedy and Tan, 2002 and 2008; Todd, 2004 and Jennings et al., 2010) was used to evaluate whether overland flow or infiltration were dominant. If the underlying geology was considered impermeable, then these uncertain areas were considered to have overland flow as its dominant hydrologic process. If the underlying geology was considered permeable, then these uncertain areas were dominated by infiltration. The determination of whether a geologic unit is impermeable or permeable was based on desktop evaluation and the best professional judgment of a Certified Engineering Geologist (CEG). This analysis was performed in GIS and the results are displayed in Table A.6 of Attachment A.

2.1.6 Dominant Hydrologic Process Results

The resulting GIS map displaying the spatial distribution of dominant hydrologic processes within the Santa Margarita WMA is provided as Figure A.1 in Attachment A. Based on this analysis, overland flow is the predominant hydrologic process in the Santa Margarita watershed management area. This endpoint was verified by the Riverside Co-Permittees as part of their review process and was also found to be consistent with the experience of engineering professionals familiar with the hydrology of the County of San Diego. An exhibit summarizing the 2016-2017 public participation efforts for the SMR WMAA is provided as Table A.7 in Attachment A.

2.1.7 Limitations

This analysis identified the dominant hydrologic processes in the SMR WMA. The methodology was based on utilizing regional, public domain datasets. Although the analysis provided a useful, rapid framework to identify the dominant hydrologic processes, it was performed as a screening-level analysis. When more precise estimates are required, it is recommended that the SMR GIS be augmented with site specific analysis.

2.2 Existing Streams in the Watershed and Locations of Existing Flood Control Structures

Murrieta Creek, Temecula Creek and Santa Margarita River are the three major watercourses examined for the stream characterization. The Permit requires a description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral; and locations of existing

flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins.

2.2.1 Summary of Datasets

The following datasets were used to characterize existing streams:

- Riverside County Flood Control and Water Conservation District (District) Facilities Area – "RCFC_WCD.RCFC_FACILITIES_AREA"
- RCFC&WCD As-Built Drawings
- Riverside County 2014 Hydromodification Susceptibility Report and Mapping
- National Hydrography Dataset – Flow lines in Riverside County
- Riverside County GIS Major Hydrology – "RIVCO.MAJOR_HYDROLOGY"
- Google Earth to assist in determining category selection (categories included in Section 2.2.2.1)
- USGS National Hydrography Dataset for San Diego County, downloaded from USGS November 2013
- USGS 7.5-minute quadrangles, compiled image of quadrangles covering San Diego County, various dates
- Floodplains: "National Flood Hazard Layer," for San Diego County provided by Federal Emergency Management Agency, October 2012
- Various datasets provided by San Diego County Co-Permittees depicting existing storm water conveyance infrastructure within their jurisdictions.
- Aerial photography of San Diego County by Digital Globe dated 2012

2.2.2 Methodology

2.2.2.1 Streambed Material and Composition

The Riverside County 2014 Santa Margarita Hydromodification Susceptibility Report and Mapping (2014 HMP) categorized existing streams and channel segments based on information obtained by the Co-Permittees and the National Hydrography Dataset. The Hydromodification Mapping identified streambed material and composition based on the categories described below:

Engineered, Fully Hardened and Maintained (EFHM): This category includes channel segments that are fully armored (e.g. concrete, soil cement, rock rip rap, etc.) on three sides and verified by as-built drawings, aerial photographs and/or a site visit. This category also includes channel segments with reinforced concrete pipes or boxes. The channel segments and associated armoring must be designed based on specific engineering criteria (e.g. specific storm event and duration), and maintained. Co-Permittees typically engineer the EFHM channels to completely contain the 100-year flow based on ultimate landuse conditions and remain stable under these flow conditions. Co-Permittees inspect the facilities regularly to maintain the improvements per design.

Engineered, Partially Hardened and Maintained (EPHM): This category includes channel segments that have some armoring (e.g. concrete, soil cement, rock rip rap, turf reinforcing mats, etc.) on less than three sides, and verified through the review of as-built plans, aerial photographs

and/or a site visit. The armoring placed in the channel may include bank and/or invert lining that has been design per specific engineering criteria. The channel segment and associated armoring must also be maintained.

Engineered, Earthen and Maintained (EEM): This category includes channel segments that are not armored, however, they have been constructed to resist Hydromodification as verified through the review of as-built plans. The channel segment must also be maintained to control invasive vegetation, correct any significant localized scouring identified during routine inspections, and maintain design grades in the channel. This category is intended to include channel segments constructed for flood conveyance, which generally have a design capacity in excess of a 10-year storm event.

Not Engineered and Earthen (NEE): This category includes natural channel segments that have been modified by anthropogenic activities. These may include floodplain encroachments by development, culverts, bridges, privately owned bank and/or invert stabilization (such as rip-rap or other forms of bank protection, roads, etc.), and other man-made modifications to the channel segment that are not necessarily continuous or designed to meet any specific engineering standard, but have modified the natural hydrologic characteristics of the channel segment. The improvements may or may not be maintained.

Natural (NAT): This category includes channel segments that are in a natural state, where the geometry has not been modified. The channel segment may or may not be maintained.

This information is shown on the "Existing Stream Structures – Santa Margarita Watershed" map in Attachment C.

2.2.2.2 Stream Structure Mapping

In addition to streambed material, the attached "Existing Streams and Structures – Santa Margarita River Watershed" map includes information for locations of physical structures. Determining the location of these structures was determined through a desktop analysis utilizing Google Earth and District as-built drawings. The following categories of structures were identified:

- Bridges
- Culverts
- Dams
- Streambed Stabilizer

A Streambed Stabilizer is an energy dissipater designed to reduce velocity of flow, maintain channel grade, and protect downstream areas from erosion.

2.2.2.3 Stream Hydrography

The Permit requires the WMAA to include information, "to the extent it is available" describing whether streams in the watershed are perennial or ephemeral. However, the available USGS National Hydrography Dataset (NHD) data used to describe streams provided information for "perennial" and "intermittent" streams, but not for "ephemeral" streams. For reference, the NHD defines "ephemeral" as: "contains water only during or after a local rainstorm or heavy snowmelt." None of the stream reaches

were classified as ephemeral in the NHD. Therefore, none are classified as ephemeral in this WMAA. Rather, consistent with the NHD classifications, existing streams in the watershed are described as either perennial or intermittent. This information is shown on the "Hydrographic Category – Santa Margarita River Watershed" map in Attachment D. This information was obtained from the USGS National Hydrography Dataset – Flowlines. The Flowlines dataset contains an attribute for streams called "Hydrographic Category", which is defined as the portion of the year a particular feature contains water. The definitions of these categories in the USGS NHD are:

- **Intermittent** – Contains water for only part of the year, but more than just after rainstorms and snowmelt.
- **Perennial** – Contains water throughout the year, except for infrequent periods of severe drought.

USGS NHD includes hydrographic category classification for many, but not all of the streams. To classify reaches of streams that did not already contain this data in NHD, these assumptions were made:

- The USGS NHD information for the stream hydrographic category has been used when available.
- When USGS NHD has "artificial paths" for portions of the stream, the hydrographic category of the upstream portion of the stream have been assigned to the stream unless other assumptions took precedence.
- If aerial photography shows large waterbody (lake, pond, irrigation pond, etc.) perennial has been assumed for the hydrographic category.
- For ponded areas shown on the aerial photography and if the USGS 7.5-minute quadrangles shows cross hatching for the area, intermittent has been assigned unless the upstream portion of the stream was assigned as perennial pursuant to the USGS NHD then assigned perennial for the ponded area.
- USGS has a dashed line for intermittent streams. USGS has a solid line for perennial streams. In some situations this information was used to assist in the determination of assigning perennial or intermittent to a stream.

The remaining stream reaches not classified as either perennial or intermittent are presumed to be ephemeral based on extensive field reconnaissance.

2.3 Current and Anticipated Land Uses

2.3.1 Summary of Datasets

The following datasets were referenced to meet this requirement:

- 2012 Existing Land Use - (SCAG, 2015)
- Anticipated Land Use – General Plan Land Use from Riverside County, 2015
- Anticipated Land Use – General Plan Land Use from the City of Menifee, 2010
- Anticipated Land Use – General Plan Land Use from the City of Murrieta, 2010
- Anticipated Land Use – General Plan Land Use from the City of Temecula, 2005
- Anticipated Land Use – General Plan Land Use from the City of Wildomar, 2016
- Ownership: "Parcels" dated December 2013, available from SanGIS/SANDAG
- Existing land use: "SANGIS.LANDUSE_CURRENT" dated December 2012, available from SanGIS/SANDAG (existing land use)
- Planned land use: "PLANLU" (Planned Land Use for the Series 12 Regional Growth Forecast

(2050)), dated December 2010, available from SanGIS/SANDAG

- Developable land: "DEVABLE" (Land available for potential development for the Series 12 Regional Growth Forecast), dated December 2010, available from SanGIS/SANDAG
- Redevelopment and infill areas: "REDEVINF" (Redevelopment and infill areas for the Series 12 Regional Growth Forecast), dated December 2010, available from SanGIS/SANDAG
- Floodplains: "National Flood Hazard Layer" in San Diego County provided by Federal Emergency Management Agency October 2012
- Multiple Species Conservation Program (MSCP), total of four datasets available from SanGIS/SANDAG: "MHPA_SD," dated 2012, (Multiple Habitat Planning Areas for City of San Diego); "MSCP_CN," dated 2009 (designations of the County of San Diego's Multiple Species Conservation Program South County Subregional Plan); "MSCP_EAST_DRAFT_CN," dated 2009 (draft East County MSCP Plan); and "Draft_North_County_MSCP_Version_8.0_Categories," dated 2008 (draft North County MSCP Plan)

2.3.2 Methodology

The "Current Land Use Map – Santa Margarita River Watershed" map, Attachment E, is based on the SCAG 2012 existing land use dataset, updated in February 2015. The "Anticipated Land Use Map – Santa Margarita River Watershed" map, Attachment F, is based on a compilation of General Plan Land Use data from the Co-Permittees (see 2.3.1). This analysis did not include specific land uses within Tribal lands.

2.4 Potential Coarse Sediment Yield Analysis

The Critical Coarse Sediment Yield analysis predicts the potential critical coarse sediment yield areas and is largely based on the Geomorphic Landscape Unit (GLU) methodology described by Booth et al. (2010). GLUs characterize the magnitude of sediment production from areas using three factors judged to exert the greatest influence on the variability of sediment-production rates: geology types, hillslope gradient, and land cover. The GLU layer was derived by overlaying hillslope, land cover, and geology, and then assigning a relative sediment-production rate (i.e., Low, Medium, and High) to each of the resulting categories. The relative sediment production rate was then estimated for each GLU using the Revised Universal Soil Loss Equation (RUSLE) following the method applied in the San Diego WMAA by Geosyntec Consultants and Rick Engineering Company (2015). An area that was identified as coarse bedrock (CB), coarse sedimentary impermeable (CSI) or coarse sedimentary permeable (CSP) coupled with a relative RUSLE rate of Medium was considered as a potential coarse sediment yield area. Whereas, an area that was identified as CB, CSI or CSP coupled with a relative RUSLE rate of High was considered as a potential critical coarse sediment yield area. The GLU approach plus the RUSLE equation application provided a useful, rapid framework to model sediment-delivery attributes of the SMR watershed. Potential critical coarse sediment yield analysis was performed in GIS and the analytical process is illustrated as a flowchart in Figure 2-2.

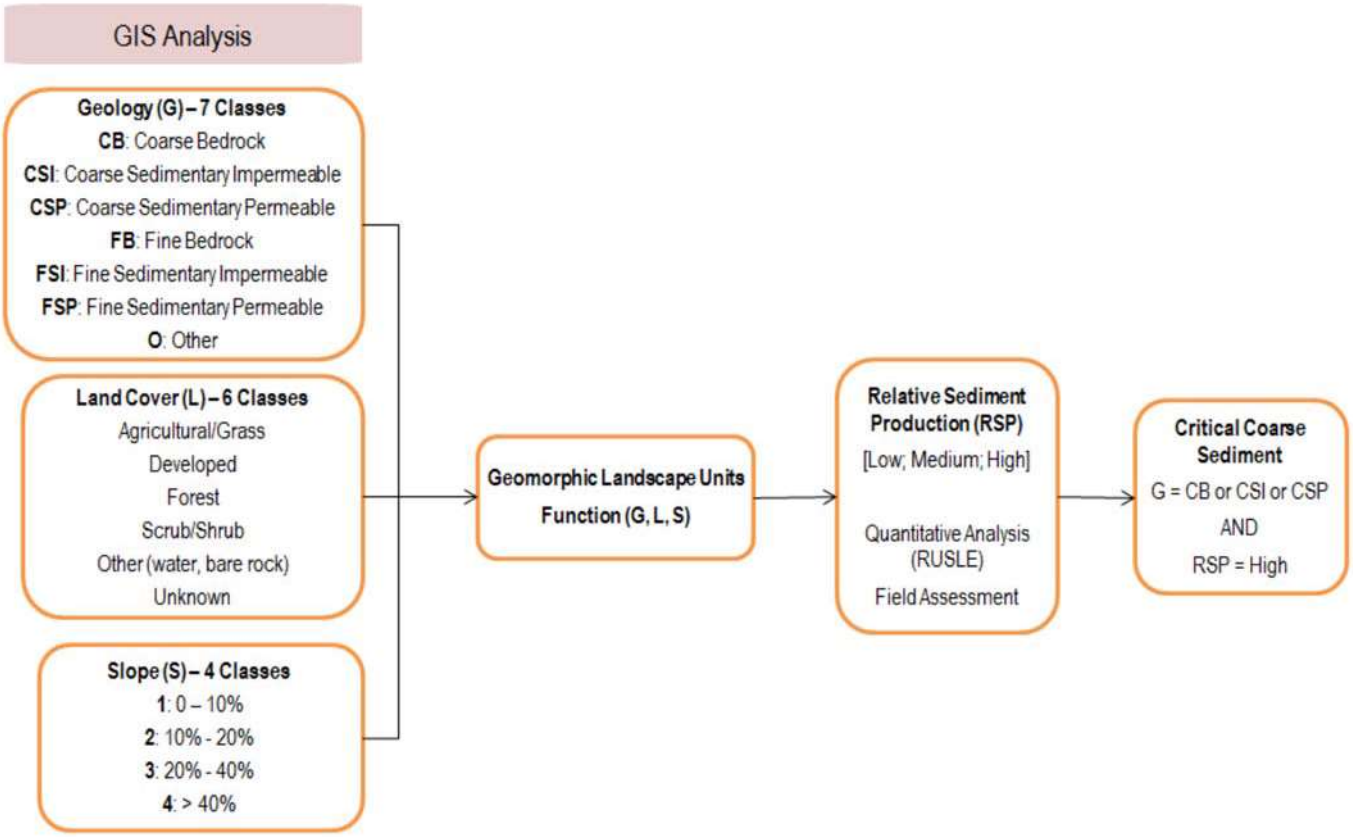

Figure 2-2. Potential Critical Coarse Sediment Field Analysis Flow Chart

2.5 Data Types and Acquisition

The geomorphic landscape unit was determined using data from the public-domain sources referenced in Table 2.3.

Table 2-3. GLU Public Domain Data Sources

GIS	Dataset	Source	Year	Description

2.5.1 Geologic Categories

The geology layer was categorized based on rock types, the predominant sediment size generated upon erosion, and their associated erodibility. The attribution (and thus the naming) of the geology classes included the following categories:

- Coarse Bedrock (CB):
- Coarse Sedimentary Impermeable (CSI):
- Coarse Sedimentary Permeable (CSP);
- Fine Bedrock (FB);
- Fine Sedimentary Impermeable (FSI);
- Fine Sedimentary Permeable (FSP); and
- Other (O).

Using GIS, 35 map units were identified in the Riverside County portion Santa Margarita watershed management area and 46 map units were identified in the San Diego County portion. Table B.1 and Table B.2 in Attachment B summarize how each of the map units related to a geologic category. The geologic categories considered to have the potential to generate coarse sediment are coarse bedrock (CB); coarse sedimentary impermeable (CSI); and coarse sedimentary permeable (CSP). An exhibit displaying the geologic categories in the Santa Margarita watershed management area is presented as Figure B.1 in Attachment B.

2.5.2 Land Cover

Land cover categories were defined using the ecology vegetation GIS map layers developed for Western Riverside County for the Riverside County portion of the Santa Margarita region (Riverside County GIS, 2014). For area within San Diego County, land cover categories were defined using the Ecology Vegetation GIS map layer developed for the City of San Diego, the County of San Diego and SANDAG. The vegetation categories in the GIS layer were grouped to match the following categories: Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other (Water), and Unknown.

2.5.3 Slope Classes

The hillslope DEM was analyzed to produce a grid of slope values, which were subsequently classified into discrete categories. The following category percentages were used to categorize hillslope gradients: 0 to 10%; 10 to 20%; 20 to 40%; and greater than 40%.

2.6 GLU Results

The result of evaluating geology, land cover and slope equated to 133 GLUs within the Riverside County portion of the study area and 112 GLUs within the San Diego County portion of the study area. The GIS analysis indicated that the Santa Margarita WMA is predominated by CB, CSI and CSP geologic categories and is therefore considered as an area with the potential to contribute coarse sediment. These GLUs were then evaluated to determine their relative sediment production to identify potential critical coarse sediment yield areas.

2.7 Relative Sediment Production

Relative sediment production was estimated for each GLU using the Revised Universal Soil Loss Equation (RUSLE) (see Equation 2).

A = R x K x LS x C x P (Equation 2), where

A = estimated average soil loss in tons/acre/year
R = rainfall-runoff erosivity factor
K = soil erodibility factor
LS = slope length and steepness factor
C = cover-management factor
P = support practice factor; assumed 1 for this analysis

Datasets used to estimate the average soil loss were acquired from public-domain sources as indicated below.

- RUSLE R Factor:
  ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_R_Factor/[1]

[1] R-Factor database provided by Geosyntec, January 2017.

- RUSLE K Factor: State Water Resources Control Board: *ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_K_Factor/*
- RUSLE LS Factor: State Water Resources Control Board: *ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_LS_Factor/*
- RUSLE C Factor: US EPA, EMAP West Metric Browser: *https://archive.epa.gov/esd/archive-nerl-esd1/web/html/wemap_download.html* for the Riverside County portion of the study area and *http://www.epa.gov/esd/land-sci/emap_west_browser/pages/wemap_mm_sl_rusle_c_qt.htm#mapnav* for the San Diego portion.

GIS analysis was used to calculate the area weighted estimate of R, K, LS and C factors using the datasets listed above. For the developed land[2] cover the C factor was adjusted to 0 for the regional estimate to account for management actions implemented on developed sites (e.g., impervious surfaces). The estimated average annual soil loss ranged from 0 to 15.2 tons/acre/year in the San Diego County portion of the Santa Margarita WMA, whereas, the estimated average annual soil loss in the Riverside County area ranged from 0 to 23 tons/acre/year.

To assess the amount of relative risk to stream channels resulting from watershed-scale changes in sediment yield and/or water delivery, the following opinions included in Technical Report 605 (Booth et al. 2010) were considered:

"The challenge in implementing this step is that presently we have insufficient basis to defensibly identify either low-risk or high-risk conditions using these metrics. For example, channels that are close to a threshold for geomorphic change may display significant morphological changes under nothing more than natural year-to-year variability in flow or sediment load.

Acknowledging this caveat, we nonetheless anticipate that changes of less than 10% in either driver are unlikely to instigate, on their own, significant channel changes. This value is a conservative estimate of the year-to-year variability in either discharge or sediment flux that can be accommodated by a channel system in a state of dynamic equilibrium. It does not "guarantee," however, that channel change may not occur—either in response to yet modest alterations in water or sediment delivery, or because of other urbanization impacts (e.g., point discharge of runoff or the trapping of the upstream sediment flux; see Booth 1990) that are not represented with this analysis.

In contrast, recognizing a condition of undisputed "high risk" must await broader collection of regionally relevant data. We note that >60% reductions in predicted sediment production have resulted in both minimal (McGonigle) and dramatic (Agua Hedionda) channel changes, indicating that "more data" may never provide absolute guidance. At present, we suggest using predicted watershed changes of 50% or more in either runoff (as indexed by change in impervious area) or sediment production as provisional criteria for requiring a more detailed evaluation of both the drivers and the resisting factors for channel change, regardless of other screening-level assessments. Clearly, however, only more experience with the application of such

[2] Developed (i.e., impervious) area data layer provided by WRCOG, January 2017.

"thresholds," and the actual channel conditions that accompany them, will provide a defensible basis for setting numeric standards."

Considering the thresholds indicated above, the relative sediment production rating for each GLU followed the criterion indicated as follows:

Riverside County

Low: Soil Loss < 3.4 tons/acre/year (GLUs that have a soil loss of 0 to 3.39 tons/acre/year produce approximately 10% of the total potential coarse sediment soil loss from the Riverside County portion of the Santa Margarita WMA)

Medium: 3.4 tons/acre/year < Soil Loss < 9.55 tons/acre/year (GLUs that have a soil loss ranging from 3.40 to 9.55 tons/acre/year produce approximately 50% of the total potential coarse sediment soil loss from the Riverside County portion of the Santa Margarita WMA)

High: >9.6 tons/acre/year (GLUs that have a soil loss greater than 9.57 tons/acre/year produce approximately 40% of the total potential coarse sediment soil loss from the Riverside County portion of the Santa Margarita WMA)

San Diego County

Low: Soil Loss < 5.6 tons/acre/year (GLUs that have a soil loss of 0 to 5.6 tons/acre/year produce approximately 10% of the total potential coarse sediment soil loss from the study area)

Medium: 5.6 tons/acre/year < Soil Loss < 8.4 tons/acre/year (GLUs that have a soil loss ranging from 5.6 to 8.4 tons/acre/year)

High: >8.4 tons/acre/year (GLUs that have a soil loss greater than 8.4 tons/acre/year produce approximately 42% of the total potential coarse sediment soil loss from the study area)

2.8 Potential Critical Coarse Sediment Yield Results

Attachment B provides tables displaying GLUs that were rated as critical coarse sediment yield areas in Riverside County and San Diego County. This analysis is summarized in tabular format as Table B.3 and Table B.4, for Riverside County and San Diego County, respectively.

The resulting GIS map showing the spatial distribution of the potential critical coarse sediment yield areas within the Santa Margarita WMA is provided as Figure B.2 in Attachment B. Based on this analysis it was estimated that 28% of the of the Riverside County portion of the Santa Margarita WMA is a potential coarse sediment yield area and 9% of the study area is a potential critical coarse sediment yield area. Most of the potential critical coarse sediment yield areas were identified to be in the Scrub/ Shrub land cover areas with hillslope gradients ranging from 20 to 40%.

For the San Diego County portion of the Santa Margarita WMA, approximately 39% of the study area is a potential coarse sediment yield area and 30% of the study area is a potential critical coarse sediment yield area. Most of the potential critical coarse sediment yield areas were identified to be on slopes greater than 30%.

2.9 Limitations for Potential Critical Coarse Sediment Yield Areas

The potential critical coarse sediment yield analysis utilized regional, public domain datasets and provided a useful, rapid framework to perform a screening level analysis for the Santa Margarita WMA. This mapping effort essentially provided a high-level analysis to provide informed decision making at a regional scale. Because of the regional-scale datasets, and commensurate data resolution used to map the potential critical coarse sediment yield areas, some areas may have been mapped that do not produce critical coarse sediment as they are existing developed areas. Furthermore, the analysis did not consider instream sediment supply or fire-induced sediment production (Lave and Burbank 2004) as this was beyond the scope of a regional study. In addition, the resolution differences among the R-factor data resulted in differences in potential critical coarse sediment yield areas near the county border (see Technical Memo in Attachment B). As such, for future projects within the Santa Margarita WMA, especially along the county border, more precise data should be required by performing a site-specific analysis along with a careful interpretation of the results. The Santa Margarita WMA area GIS should then be supplemented with this site-specific data. Ultimately, the Santa Margarita WMA data for the potential critical coarse sediment yield areas should be verified in the field according to the procedures outlined in the Model BMP Design Manual and/or jurisdiction specific BMP Design Manual.

3 Potential Candidate Projects

The Permit requires Co-Permittees to use the results of the WMAA to identify and compile a list of candidate projects that Priority Development Projects could potentially use as alternative compliance options. Criteria for selecting candidate projects includes (San Diego RWQCB, 2015):

Structural Projects

1. Stream or riparian area rehabilitation; projects will restore streams to a natural, stabilized condition that can accommodate both historic and future hydromodification impacts.
2. Retrofittingexistinginfrastructuretoincorporatestormwaterretentionortreatment; projects will add or modify structural BMPs where practices do not currently exist, are ineffective, or can be significantly enhanced.
3. Regional; projects will treat stormwater, improve water quality, protect downstream channels, or reduce flooding, from a drainage area consisting of more than one development.
4. Water supply; projects will capture stormwater and infiltrate, pump or otherwise recharge groundwater, surface reservoirs, or other water supply systems.

Natural System Management Practices

5. Land Restoration; projects will restore currently developed land back to a stabilized, predevelopment condition.
6. Land Preservation; projects will prevent increases in stormwater runoff volumes and preserve floodplain function through preservation of undeveloped land.
7. Stream Rehabilitation; projects that restore a stream to a natural, stabilized condition that can accommodate both historical and future hydromodification impacts.

Potential candidate projects within the SMR are described below.

3.1 Candidate Projects for the Middle SMR Subwatershed

MEADOWVIEW STREAM RESTORATION PILOT PROJECT: The project will reduce public and water quality hazards due to existing erosion by removing vertical cut banks and restoring the natural functions of the stream using primarily soft-armoring and vegetative techniques. The project is located in the City of Temecula. This project will be a stream restoration project and be eligible for hydromodification flow control credit by providing permanent stabilization of the stream.

SANTA GERTRUDIS VALLEY- BROWNING STREET WATER QUALITY BASIN: The project will alleviate water quality concerns associated with dry weather flows at the system outfall at the northwest corner of Encanto Road, in the French Valley area in unincorporated Riverside County. This will be a regional project that improves water quality. Given the primary purpose of the project is to treat dry weather flows, it is unclear what benefit will be provided to stormwater. Coordination will continue to determine if dry weather flow treatment is eligible for stormwater pollutant control credits.

WILDOMAR MDP LATERAL C BASIN: The project will reduce flooding along Bundy Canyon Wash in the City of Wildomar. The project consists of a 19-acre footprint detention basin and outlet proposed at the

southeast corner of Monte Vista Drive and Bundy Canyon Road to collect and attenuate runoff. The detention basin will incorporate water quality features to alleviate dry weather concerns in the City of Wildomar. This project will be a regional project. The project has the potential to generate both hydromodification and/or stormwater pollutant control credit depending on the final design of the facility.

COUNTY OF RIVERSIDE INTEGRATED MITIGATION PROJECT: The project is located in the French Valley area in unincorporated Riverside County and proposes to restore and enhance habitats that have been lost or degraded as a result of past agricultural and other human activities. The proposed project includes channel grading, diversion channels, check dams, habitat preservation, and habitat enhancement and creation. The project will be a stream rehabilitation project with the potential to generate hydromodification and/or stormwater pollutant control credit.

TEMECULA CREEK STREAMBED STABILIZATION: The project proposes to restore and stabilize the reach of Temecula Creek between Pechanga Parkway and Avenida Missiones, just downstream of the existing engineered channel. The project will reduce erosion susceptibility along this reach of the creek to reinstate the Temecula Creek hydromodification exemption. This will be a stream rehabilitation project with the potential to generate hydromodification credit.

MURRIETA CREEK CHANNEL FLOOD CONTROL PROJECT: The project includes construction of a 250 acre detention basin that will attenuate flows from the over 150 square mile watershed. It includes: creation of over 160 acres of wildlife habitat, development of a 50 acre regional sports park, reduction in downstream flood flow peaks, creation of regional sports park within the detention basin. This will be a regional project that will have the potential to provide hydromodification credit and stormwater pollutant control credit.

Exhibit showing approximate project location for Middle SMR Subwatershed candidate projects can be found in the Candidate Projects for the Upper SMR Subwatershed map located in Attachment J.

The projects above represent those projects planned by the District as Principal Permittee. The Co-Permittees have convened a Technical Advisory Group of regional stakeholders to develop a framework for facilitating the use of Alternative Compliance in those jurisdictions that choose to adopt an alternative compliance program. As part of these discussions, the Co-Permittees have noted that a variety of individual and programmatic actions may be taken that potentially can be credited using the adopted Water Quality Equivalency (WQE) framework (San Diego RWQCB, 2017). Such actions may include, but are not limited to, implementing stormwater runoff treatment and control measures for dirt and gravel roadways; modifying drainage and surfacing at municipal facilities to provide treatment and control of previously untreated surfaces; "over-sizing" stormwater treatment measures in conjunction with public roadway projects; and providing enhanced stormwater treatment within linear projects such as recreation pathways.

While many of these approaches would fall under the broad category of (2) above, "retrofitting existing infrastructure to incorporate storm water retention or treatment," it is not possible to identify all potential project options that may emerge over the period that this WMAA is in effect. These types of retrofits or regional projects, which have the potential to support enhanced water quality and robust implementation of Alternative Compliance, typically are identified in the course of regular planning and design processes for

private development or public works projects. Therefore, the Co-Permittees emphasize that projects that are identified in the design process, and that can be credited properly in a manner consistent with the adopted WQE, are considered to be Candidate Projects for Alternative Compliance. These projects will be added to the WMAA on an annual update basis as they are identified by the Co-Permittees.

3.2 Candidate Projects for the Lower SMR Subwatershed

Analysis for the Lower SMR Subwatershed was previously conducted for the 2015 San Diego County Regional WMAA. Summaries of candidate projects within the Lower SMR Subwatershed are provided in the following sections.

3.2.1 Santa Margarita River Habitat Assessment and Enhancement Plan

The purpose of the Santa Margarita River Steelhead Habitat Assessment and Enhancement Plan is to develop a Watershed Management Area (WMA) restoration plan for the anadromous waters of the Santa Margarita River and major tributaries that emphasizes the needs of southern steelhead. The primary objective is to document existing WMA conditions, identify limiting factors to steelhead recovery, and provide prioritized solutions to address limiting factors to steelhead recovery. This objective will be accomplished through the following tasks: 1) Compile information on existing and historical conditions, including available data from studies on Camp Pendleton, and solicit input from stakeholders; 2) Conduct a WMA habitat assessment using California Department of Fish and Wildlife (CDFW) protocols that documents passage barriers and limiting habitat factors; 3) Develop prioritized recommendations for restoration opportunities and prepare a Steelhead Habitat Assessment and Enhancement Plan.

3.2.2 Santa Margarita River Fish Passage Design - Sandia Creek

A completed steelhead habitat assessment study by Cardno ENTRIX and Trout Unlimited – South Coast Chapter mapped habitat quality and fish passage barriers in detail upstream of Camp Pendleton (2013) and cited two barriers (SMR01 and SMR02) that need to be remediated in the main stem for fish passage upstream. This project has requisite engineering tasks by the WEST Consultants engineering team to arrive at design alternatives for the barriers. These include fish passage and flood flow determination, topographic survey, hydraulic analysis and fish passage evaluation, sediment transport and scour analysis, basis of design report (30-40% plans) and 65% design plans for review by relevant Co-Permittees. This project will capitalize on the opportunity for public outreach and education in this area. The project site has public access to the Santa Margarita River and to local hiking and riding trails from the nearby communities of Fallbrook and Temecula that have close regional ties to the River. The development of backcountry communities in the priority WMAs presents challenges to habitat and connectivity, and increases demand on limited water resources. This indicates a need for raising public awareness to mitigate human impact, restore ecosystems and improve water and resource management practices.

3.2.3 Fallbrook Public Utilities District Recycled Water Storage

The project would construct a recycled water storage tank that would allow for the Fallbrook Public Utility District (FPUD) to store and utilize recycled water during periods of the day when recycled demands exceed wastewater supplies. Currently, the FPUD utilizes make-up potable water to supplement the recycled water supply. Because there is currently no storage and the high demand periods occur during the day when wastewater flows are low, a large volume of make-up water is required to maintain service. It is projected

that 132 acre-feet of make-up water will be used in 2010, which would be 25% of the total recycled water supply. This project would construct a below grade uncovered storage structure located adjacent to the existing equalization basin at the Water Recycling Facility. The project would be connected hydraulically to the recycled water wet well in the contact tank, which would allow utilization of stored recycled water in place of potable make-up water.

3.2.4 Implementing Nutrient Management in the Santa Margarita River Watershed - Phase I/II

The project aims to establish the science and stakeholder consensus to support the adoption of alternative nutrient Water Quality Objectives (WQOs) in the SMR WMA through the San Diego RWQCB Basin Plan triennial update. It will optimize irrigation practices by coordinating with local Resource Conservation Districts. Major tasks include: 1) facilitate SMR WMA stakeholder group to guide activities; 2) conduct monitoring and special studies to address data; 3) develop proposed nutrient WQOs for the SMR and estuary based, and 4) optimize irrigation on agricultural lands. This effort would model for the region, reduce nutrient loads and conserve water. The project leverages an investment of over $2 million contributed by WMA stakeholders since 2007.

3.2.5 Implementing Nutrient Management in the Santa Margarita River Watershed Phase III

This project aims to establish the science and seek stakeholder consensus to support the adoption of alternative nutrient Water Quality Goals (WQGs) in SMR watershed and to implement nutrient management activities. The project is the third phase of the overall project that will develop proposed nutrient WQGs for the SMR Estuary (Phase I), provide additional site-specific studies and modeling of nutrient sources and responses in the main stem of the Lower SMR River (Phase II), and in Upper SMR River and selected tributaries (Phase III) that may lead to development of nutrient site-specific objectives (SSOs) or other regulatory alternative by the SDRWQCB that are protective of beneficial uses. Nutrient management activities will include agricultural irrigation system evaluations, residential and equestrian property conservation plans and educational workshops, and will include a rebate program to encourage irrigation retrofits.

The project goals are to:

1. Maximize community involvement in SMR watershed by continued stakeholder group facilitation (established in Phase I).
2. Continue work with the group to obtain feedback and critical review of technical work products to achieve consensus on proposed WQGs.
3. Continue core monitoring and special studies to address data gaps required to develop WQGs for the SMR and tributaries.
4. Develop proposed nutrient WQGs for the SMR and tributaries, as needed, based on sound science and local data.
5. Develop proposed nutrient WQGs for selected streams in SMR watershed that are protective of beneficial uses.
6. Encourage the implementation of BMPs to reduce nutrient loading into the SMR and its tributaries.

3.2.6 Monitoring, Special Studies and Modeling will be conducted in selected SMR tributaries to further refine WQGs that are protective of beneficial uses for the SMR Watershed. Collected data and model-generated information will be used to track nutrient loads and sources, and where warranted, this data and information will be used to identify areas of the watershed where implementation of nutrient management activities would be the most beneficial. Collected data and model-generated information efforts during Phase III can be used alone or in combination with any existing data collected during Phases I and II, and any other available studies.

4 Hydromodification Exempt Areas

Hydromodification, which is caused by both altered stormwater flow and altered sediment flow regimes, can cause degradation of creeks, streams, and associated habitats. The purpose of the hydromodification management requirements in the Regional MS4 Permit is to maintain or restore more natural hydrologic flow regimes to prevent accelerated erosion and other impacts in downstream receiving waters.

In some cases, priority development projects may be exempt from hydromodification management requirements if the project site discharges runoff to receiving waters that are not susceptible to erosion (e.g., a lake, bay, or the Pacific Ocean) either directly or via an engineered facility. According to Section F.1.h.4 of the Permit. Each Co-Permittee has the discretion to exempt a priority development project from hydromodification management where the project:

(a) Discharges stormwater runoff into underground storm drains discharging directly to water storage reservoirs and lakes;

(b) Discharges stormwater runoff into conveyance channels whose bed and bank are concrete lined all the way from the point of discharge to water storage reservoirs and lakes; or

(c) Discharges stormwater runoff into other areas identified in the HMP as acceptable to not need to meet the requirements of Section F.1.h by the San Diego Water Board Executive Officer.

The June 2013 Santa Margarita Region Hydromodification Management Plan (HMP) identified certain exemptions from hydromodification management requirements by presenting "HMP Exemptions." The Regional MS4 Permit maintains some of these HMP exemptions. However, some of the exemptions are not included under the Regional MS4 Permit unless the area or receiving water is mapped in the WMAA. The intent of this section is to provide supporting technical analyses for exemptions that are recommended by the WMAA.

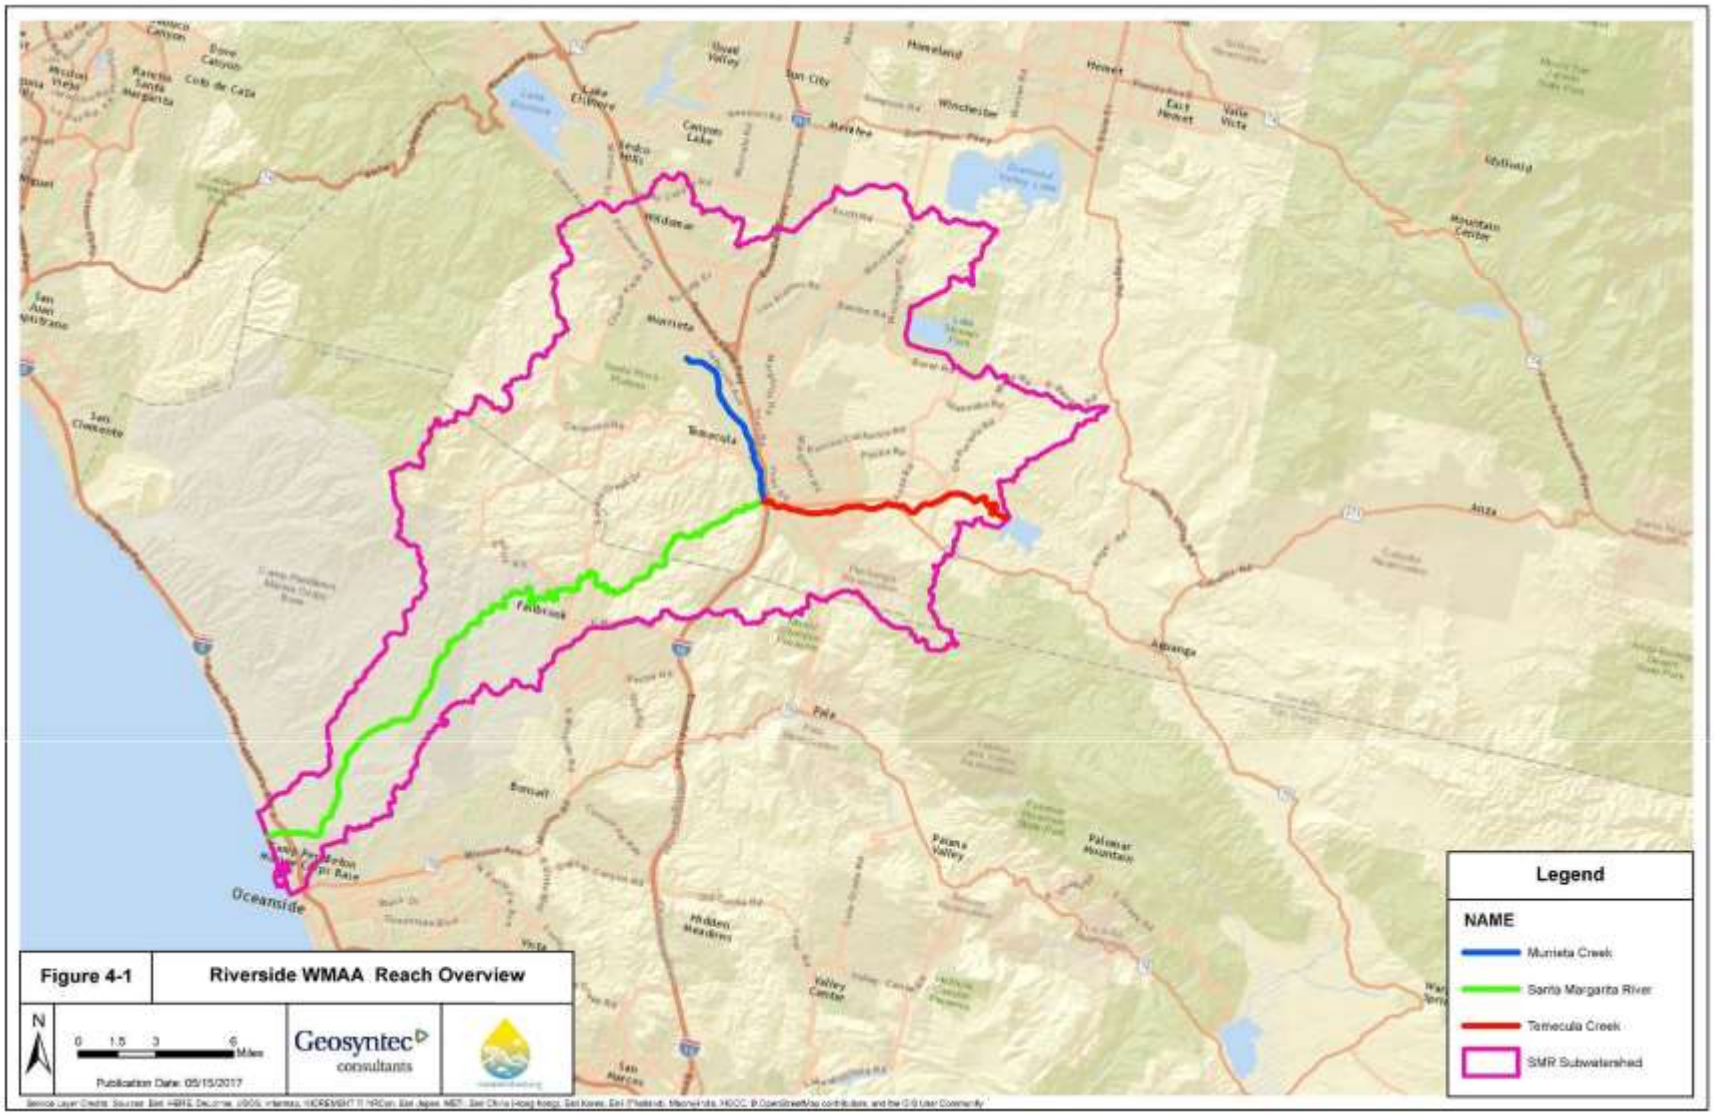
4.1 Additional Analysis for Hydromodification Management Exemptions

This section documents additional analysis performed to further evaluate the following exemptions (See Figure 4-1) that were approved by the San Diego Regional Board with the June 2013 Santa Margarita Region Hydromodification Management Plan. This study provides additional analysis, data, and rationale for supporting or eliminating the following existing exemptions but does not propose or study any new exemptions.

- Santa Margarita River

- Upstream Limit: At Origin, i.e. Confluence with Temecula Creek and Murrieta Creek
- Downstream Limit: Outfall to Pacific Ocean

- Temecula Creek
  - Upstream Limit: Outflow of Vail Lake
  - Downstream Limit: Confluence with Santa Margarita River
- Murrieta Creek
  - Upstream Limit: 850 feet upstream of Hawthorn Street
  - Downstream Limit: Confluence with Santa Margarita River



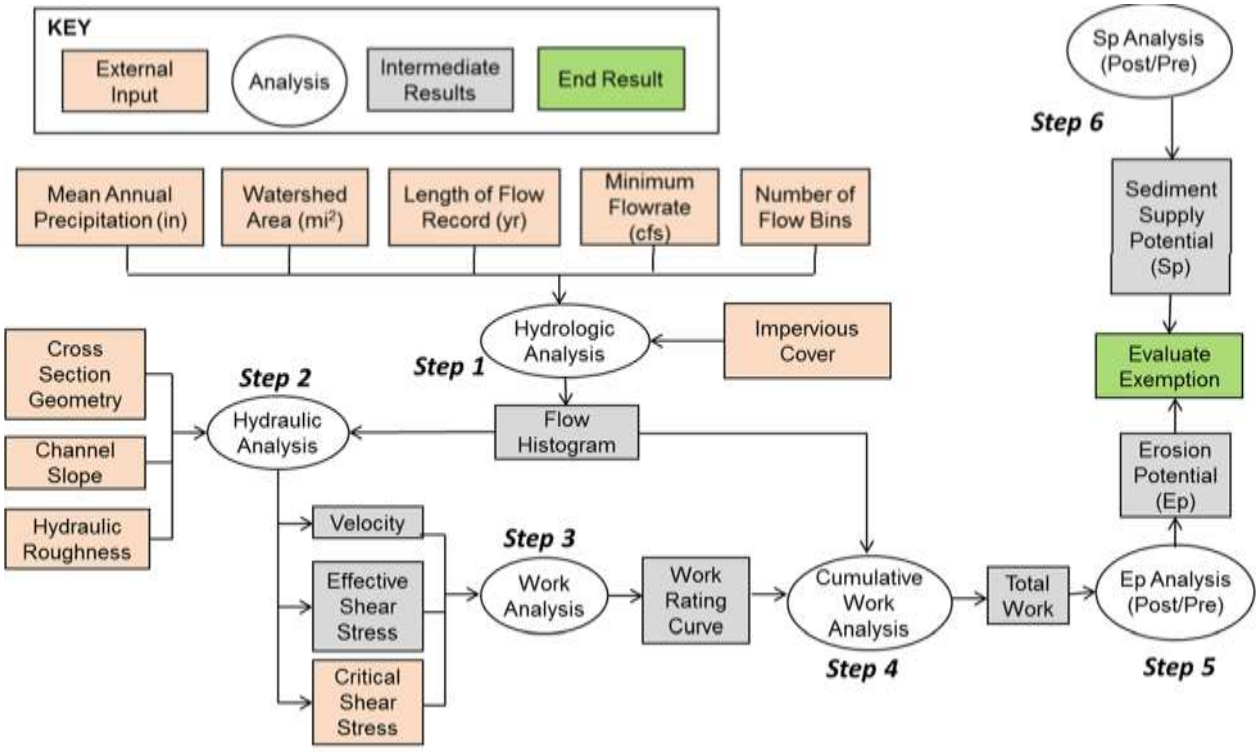


Figure 4-1. WMAA Reach Overview

4.2 Approach for Evaluating Hydromodification Management Exemptions

The approach (see diagram below) in this cumulative hydromodification impacts study accounts for: (1) hydrology, (2) channel geometry, (3) bed and bank material, and (4) sediment supply. This approach compares long-term changes in sediment transport capacity, or in-stream work, and sediment supply at specific sections of the creek for existing and future land use conditions. The ratio of future to existing condition transport capacity, or work, is termed Erosion Potential (Ep). The ratio of future/existing condition bed sediment supply is termed Sediment Supply Potential (Sp). To calculate Ep, the hydrology, channel geometry, and bed/bank materials are characterized for the existing and future conditions. To calculate Sp, the sediment supply factor is characterized for the existing and future conditions.

The findings in this study propose exemption for a given river reach if the analysis satisfies the following criteria:

- Ep < 1.05 when d50 < 16 mm or Ep < 1.20 when d50 > 16 mm, and;
- Sp > 0.5

The following bullet points provide basis for the criteria listed above:

- For Ep

  According to the Journal of Hydrology article titled Channel Enlargement in Semiarid Suburbanizing Watersheds: A Southern California Case Study (Hawley and Bledsoe, 2013): "The threshold corresponding to the presence/absence of headcutting varied based on substrate type, and was roughly quantified as a sediment-transport ratio greater than ~1.20 in systems with a median grain size > 16mm, and [Ep] ~ 1.05 when d50 < 16 mm"

- For Sp
- Technical Advisory Committee (TAC) recommendation
- County of San Diego BMP Manual Appendix H requires Sp > 0.5

According to SCCCWRP Technical Report 605, 2010, When the criteria for Ep and Sp are met, then changes in sediment supply and erosion potential are not anticipated to instigate, on their own, significant channel changes that would destabilize the stream. At present, the report suggests using predicted watershed changes of 50% or more in either runoff (as indexed by change in impervious area) or sediment production as provisional criteria for requiring a more detailed evaluation of both the drivers and the resisting factors for channel change, regardless of other screening-level assessments (SCCWRP Technical Report 605, 2010).

4.2.1 Erosion Potential Analysis

The following steps were implemented to estimate Erosion Potential (Ep):

- **Step 1** – Hydrologic Analysis
  - Due to limited flow data, a flow duration equation developed for Southern California (Hawley and Bledsoe, 2011) was used to estimate existing and future flow histograms for each watershed.
  - The change in impervious cover between existing and future development conditions was estimated using the existing and anticipated land use layer summarized in section 2.3.
    - Planning land use layers from Section 2.3 were used to estimate the existing impervious area and identify the developable parcels in each watershed. A GIS exercise was performed to identify the developable parcels in each watershed that will be exempt from hydromodification management requirements if the exemption is granted.
    - GLU analysis and its associated quantitative analysis described in Section 2.4 were used to determine Sp metric for each watershed. In this study, coarse sediment supply changes were limited to changes in hill slope erosion between existing condition and future condition (for parcels that are proposed to be exempt from hydromodification management) of the watershed. It was assumed that the changes in instream sediment supply between existing and future condition for these large depositional river systems are very minimal.
  - The process for quantifying existing vs future land use is as follows
    - Obtain and process land use data and impervious raster
      - Clip impervious raster (https://www.mrlc.gov/) to watershed boundary; Values of raster vary from 0 to 100 and represent percent impervious
      - Process land use data based on SCAG codes from 1100 to 9999
    - Perform zonal statistical analysis using ArcGIS
      - Imperviousness for each type of land use is calculated
    - Analyze results for imperviousness in each SCAG code
      - Determine total area corresponding to each SCAG code

        - Using simple average for each impervious surface coefficient associated with each SCAG code global imperviousness is calculated for each jurisdiction
    - Assumptions for percent imperviousness for each land use type were based on:
        - Office of Environmental Health Hazard Assessment (OEHHA) tool for the impervious fraction determination for areas within Riverside County.
        - The information provided in the San Diego County Imperviousness Study (County of San Diego, 2010) for areas within San Diego County.

- **Step 2** -Hydraulic Analysis
    - Critical cross section was selected for performing hydraulic analysis for each reach.
- **Step 3**: Work Analysis: The simplified effective work equation shown below is used to calculate the work done for each flow bin.
- $W = (r - r_c)^{l.S}V$

  Where
  W = Work (dimensionless)
  τ = effective Shear Stress [lb/ft^2]
  τ_c = Critical Shear Stress [lb/ft^2]
  V = Flow Velocity [ft/s]

- **Step 4**: Cumulative Work Analysis: Cumulative work is a measure of the long-term total work or sediment transport capacity performed at a given stream location. Cumulative work incorporates both discharge magnitude and flow duration distributions for the full range of simulated flow rates. Cumulative work is calculated by multiplying work and duration for each bin. Total work is calculated through summation of work from all flow bins.
- **Step 5**: Ep Analysis: Ep is calculated by dividing the total work of the future condition by that of the existing condition. The existing river reaches analyzed appear relatively stable and have not experienced excessive geomorphic instability due to the alteration of the drainage areas. Given the stable condition of the existing channels, the existing condition was used as the baseline condition instead of natural.

Steps 1 to 5 were performed in Excel. Ep estimates are included in the attachments and are summarized in a table in the corresponding section.

4.2.2 Sediment Supply Potential Analysis

- **Step 6** – Sp Analysis; Sp was estimated using the following equation; it was developed with input from Technical Advisory Committee members formed by the San Diego County Co-Permittees to develop streamlined guidance that provides applicants with simplified methods to determine impacts to coarse sediment delivery based on robust scientific principles. Sp is a metric to evaluate the changes in bed sediment supply for susceptible receiving channels of concern. Sp is directly proportional to Ep (Erosion potential). Sp has to be greater than 0.5, to substantiate a hydromodification exemption, based on current understanding of risks to receiving waters arising from changes in sediment production. Sp is estimated based on the following equation

  $Sp = 0.7*SY_{RUSLE}+0.3*SY_{NHD}$.

The hillslope coarse sediment supply (SY_{RUSLE}) was estimated using the quantitative results from Section 2.4. First, the watershed coarse sediment soil loss was estimated for all GLUs producing coarse sediment below the reservoirs in the existing condition. Then, the future-condition coarse sediment soil loss was estimated by subtracting the developed parcel below the reservoirs soil loss from the existing soil loss.

4.2.3 Criteria for Exemption

The following assessments were performed to evaluate if the projects directly discharging to the reaches discussed in Section 4.1 (see Figure 4.1) should be exempt from hydromodification management requirements. The criteria used in this analysis are consistent with the criteria approved in the San Diego Regional WMAA for determining if exemptions are appropriate, and are summarized below:

- For Flow Control:
  - Erosion potential (Ep) for the fully built-out condition compared to the existing condition shall be less than 1.20 when the median grain size (d_{50}) > 16 mm (Hawley and Bledsoe, 2013).
- For Coarse Sediment Supply:
  - Sediment supply potential (Sp) shall be greater than 0.5, based on current understanding of risks to receiving waters arising from changes in sediment production (SCCWRP Technical Report 605, 2010). Refer to the San Diego Regional WMAA report (Prepared by Geosyntec and RICK, 2015) and the San Diego Model BMP Design Manual for additional details about this criterion.

The watershed characterization maps summarized in Chapter 2 were used to evaluate the applicability of hydromodification management requirements.

4.3 Santa Margarita River

The extents of the Santa Margarita River (Upstream Limit: At Origin, i.e. Confluence with Temecula Creek and Murrieta Creek; Downstream Limit: Outfall to Pacific Ocean) for which hydromodification assessment is performed is shown in Figure 4-1. The river flows southwest through Temecula Canyon at the south end of the Santa Ana Mountains and then enters the coastal region where the river forms a large flood plain as it crosses Camp Pendleton Marine Corps Base before it enters the Pacific Ocean. The upper 15 miles of the river is characterized by a relatively narrow channel, slopes of approximately 1%, significant meanders and rocky terrain. The lower 15 miles within the coastal plain is characterized by a broader channel, shallower slopes of approximately 0.3%, and sandy substrate. Due to the two discrete channel types with varying substrate and associated particle size, two field assessments were conducted to characterize d50 and evaluate stability. Given that erosion potential (Ep) is greatest in the steepest channel, a critical section will be considered at the steepest point in the river profile. Sediment Supply (Sp) will be applied to the tributary watershed for existing and future conditions to quantify reductions in future critical course sediment supply. An additional assessment was conducted in the coastal plain to quantify the (Ep) and evaluate stability.

4.3.1 Erosion Potential Analysis

See section 4.2.1 for a description of the entire erosion potential analysis. This section includes specific information on erosion potential in the extents of the Santa Margarita River:

- The table below presents the input parameters used to construct flow histograms, as well as the estimated channel slope at the two cross sections.

Exempt River Reach	Area below the reservoirs (sq. miles)	Mean Annual Precipitation (in)	Length of Daily Flow Record (Years)	Channel Slope (ft/ft)
Upstream Santa Margarita River	352	16.3	30	0.025
Down Stream Santa Margarita River	352	16.4	30	0.003

- The upstream critical cross section along the reach for Ep analysis was selected by plotting the longitudinal profile of the reach (Figure 4-2) and selecting a cross section along the steeper portion of the channel where flow velocities would tend to be higher. A critical flow rate of 0.5Q2 was assigned to estimate the critical shear stress for the analyzed cross section.
- The downstream cross section along the reach for Ep analysis was selected based on its locations within the coastal region. The specific section investigated was selected on what could be accessed safely within Camp Pendleton. Critical shear stress for the reach was estimated based on Fischenich 2001, Stability Thresholds for Stream Restoration Materials. A value of 0.02 was assigned to estimate the critical shear stress for the analyzed cross section.

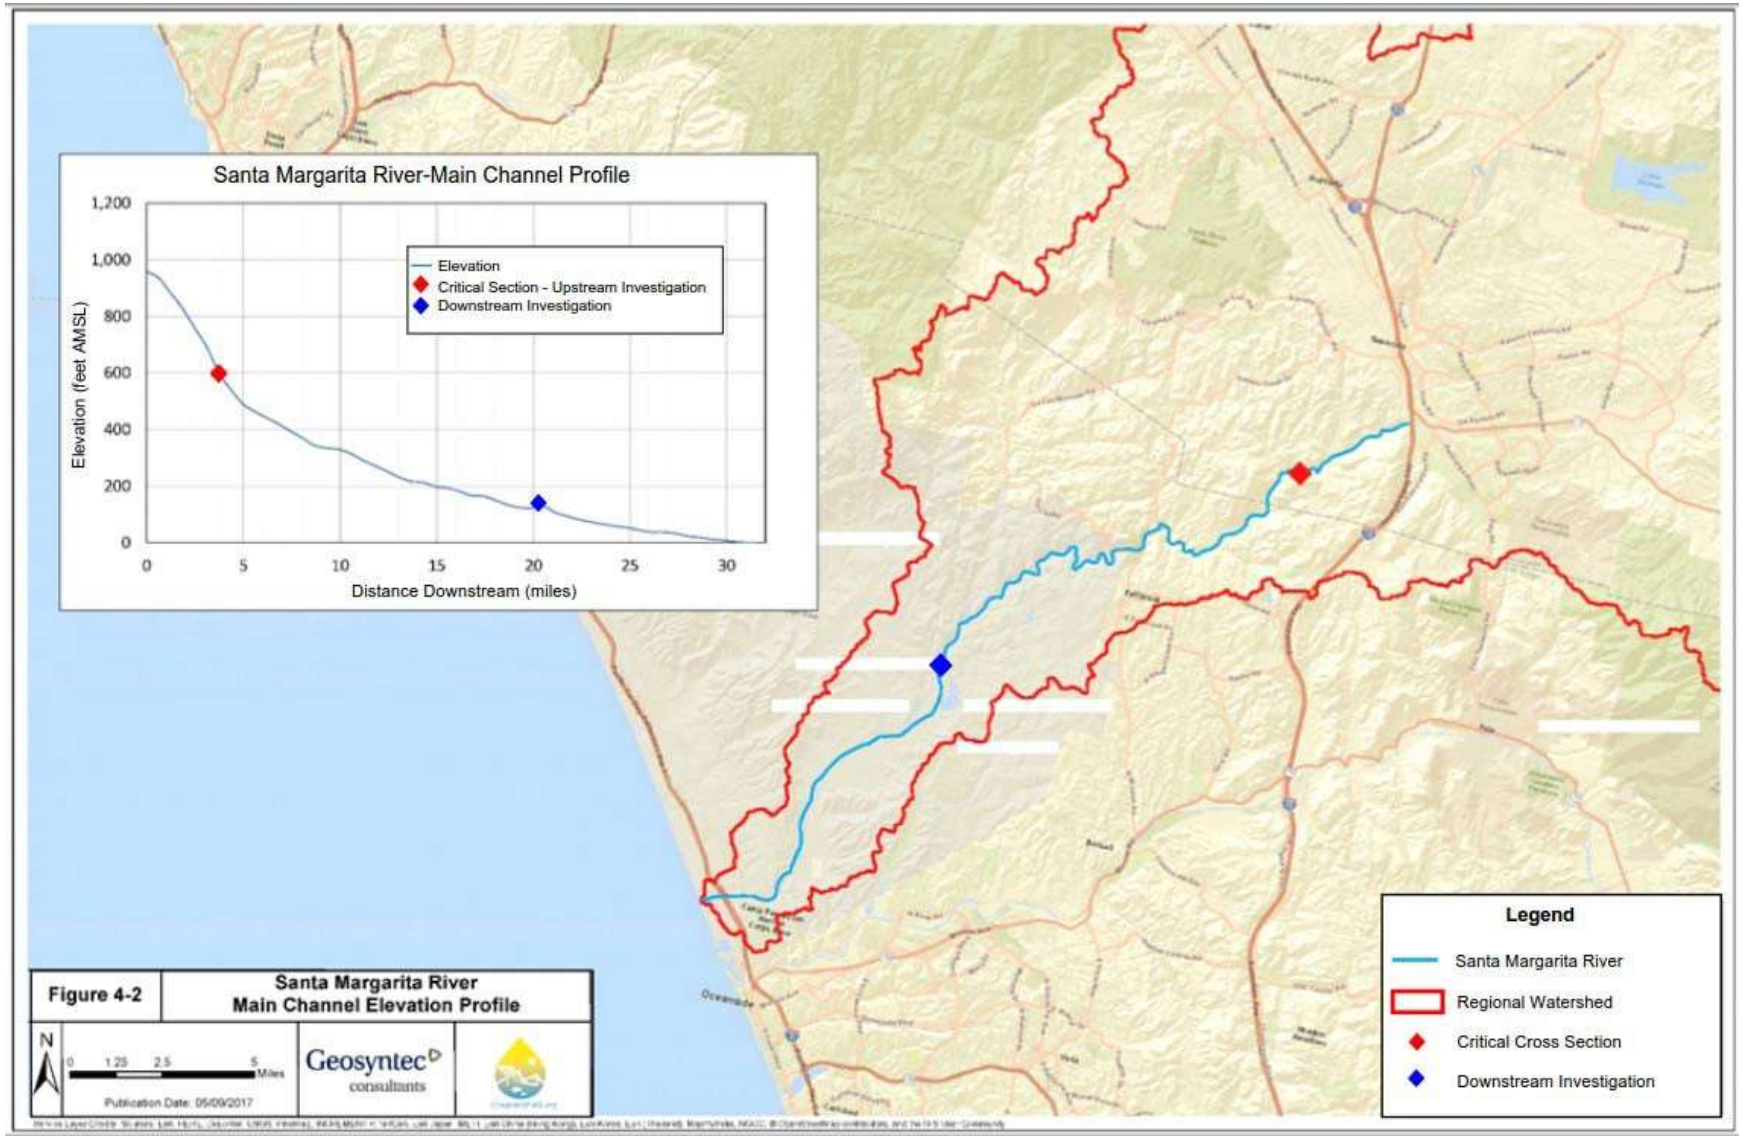

Figure 4-2. Santa Margarita River: Main Channel Elevation Profile

Upstream Investigation

- Field assessment was conducted on June 16, 2017 by Geosyntec Consultants (Geosyntec) within the vicinity of the critical cross section on the Santa Margarita River to assess channel stability and estimate the median grain size of the channel bed material. Based on the results of the field screening performed, the equivalent grain size for the reach with the critical cross section was determined to be greater than 16 mm. Representative channel and flood plain photos based on the field visit are shown in Figure 4-3 and Figure 4-4 below. As can be seen in both photos, the bed material is comprised mostly of large cobble and boulders well in excess of 128 mm. No evidence of downcutting or lateral adjustment was observed. Per SCCWRP Technical Report No. 606, the channel was determined to be consistent with a CEM Type 1 channel.
- Bed Material – Coarse/Armored Bed with boulders/cobbles, d50>128 mm
- Channel Evolution Model - CEM Type 1

Figure 4-3. Upstream Representative Channel

Figure 4-4. Upstream Representative Floodplain

Downstream Investigation

- Field assessment was conducted on March 20, 2018 by Riverside County Flood Control and Water Conservation District staff, within the downstream reach in the vicinity of Camp Pendleton on the Santa Margarita River to assess channel stability and estimate the median grain size of the channel bed material. Based on the results of the field screening performed, the equivalent grain size for the reach was determined to be greater than 16 mm. Representative channel and flood plain photos based on the field visit are shown in Figure 4-5 and Figure 4-6 below. As can be seen in both photos, the bed material is comprised mostly of sands, silts and gravel in excess of 16 mm. No evidence of downcutting or lateral adjustment was observed. Sedimentation was apparent throughout the stream bed. Per SCCWRP Technical Report No. 606, the channel was determined to be consistent with a CEM Type 1 channel.
- Bed Material – Sand and Gravel, d50>16 mm
- Channel Evolution Model - CEM Type 1

Figure 4-5. Downstream Representative Channel

Figure 4-6. Downstream Bed Material

EP estimates are included in Attachment H and are summarized in table below.

Exempt River Reach	Area below the reservoirs (Vail Lake and Skinner Reservoir) (acres)	Impervious Area (acres) [%]			Upstream Ep (Post/Pre)	Downstream Ep (Post/Pre)
		Pre	Post	Increase	[Criteria <1.20]	[Criteria <1.20]
Santa Margarita River	225,505	29,772 [13.2]	40,106 [17.8]	10,334 [4.6]	1.13	1.13

The estimated Ep is smaller than the threshold value of 1.20, hence the flow control criteria for Ep is considered to be met. Ep values less than 1.2 indicate the transport capacity of instream work for pre and post conditions will not be significantly altered or lead to unstable conditions. The factor of safety = 1.13/1.20 = 0.94, or a 6-7% factor of safety.

4.3.2 Sediment Supply Potential (Sp) Analysis

Results from this calculation (see Section 4.2.2 for approach) are presented in the below table.

Exempt River Reach	Coarse Sediment Soil Loss (tons/yr.)			SY_{RUSLE}
	Pre	Developed Parcels (downstream of Reservoirs)	Post [Pre – Developed Parcels]	
Santa Margarita River	1,352,421	432,298	920,123	0.68

Disturbance to NHDPlus channels are protected through 401 water quality certifications or waste discharge requirements issued by the RWQCB, so it is assumed that SY_{NHD} =1.

$$\text{Estimated Sp} = 0.7*SY_{RUSLE}+0.3*SY_{NHD} = 0.7*0.68 + 0.3*1 = 0.78.$$

The estimated Sp is greater than 0.5 so the reach meets the sediment supply potential criteria. The value being greater than 0.5 indicate that sediment supply for pre and post conditions will not be significantly

different and adequate sediment supplies to the stream will continue. The factor of safety = 0.78/0.5 = 1.56 or 56% factor of safety.

4.3.3 Recommendation

Based on the results from this study, it is recommended that hydromodification management exemption be reinstated for projects discharging runoff directly to the Santa Margarita River (Upstream Limit: At Origin, i.e. Confluence with Temecula Creek and Murrieta Creek; Downstream Limit: Outfall to Pacific Ocean).

Each municipality must define/approve "direct discharge" based on the project site conditions. To qualify for the potential exemption, the outlet elevation must be between the river bottom elevation and the 100-year flood plain elevation and properly designed energy dissipation must be provided.

The Santa Margarita River Estuary (Estuary) is on the 303(d) impairment list for eutrophic conditions. While no analysis has been performed within this assessment, the proposed exemption is not anticipated to conflict with water quality objectives in the Estuary for the following reasons.

1. Nitrogen and Phosphorus loading from the watershed will not be measurably different with or without the proposed hydromodification management exemption. The primary driver of the eutrophic conditions in the Estuary is during dry weather. The exemption has no effect on dry weather discharges or rising groundwater inputs to the Estuary in which the eutrophication symptoms are most prevalent.
2. According to the exemption analysis, this stream system is anticipated to be stable, (i.e., excessive or accelerated erosion is not expected), such that, sediments carrying nutrients would not increase downstream. Furthermore, Ep and Sp analysis indicate that channel erosion and transport will not be significantly changed and therefore instream channel derived sediment and associated nutrients are not expected to increase.
3. Water Quality Analysis Simulation Program model results, included in the Model Application Report, notes that the hydromodification controls are unlikely to have a significant impact on the Estuary. Implications of the findings is that wet weather structural BMPs, which generally cost an order of magnitude or higher to implement, may not provide any additional environmental benefits to the Estuary than implementation of dry weather BMPs alone.
4. The watershed of the Santa Margarita River downstream from the reservoirs totals 352 square miles. The area being evaluated for the proposed hydromodification exemption totals approximately 10 square miles or 2.8 % of the total watershed. Given the relatively small area in which the proposed hydromodification exemption will be applied within the greater Santa Margarita Watershed, the exemption is not expected to exacerbate eutrophic conditions.
5. Within the hydromodification exemption area, priority development projects in the absence of hydromodification requirements will still be required to provide treatment of the 85th percentile rainfall with an effective combination of BMPs that target the constituents of concern such as nitrogen and phosphorus. Additionally, all priority development projects will implement peak flow control BMPs as required by Riverside County Flood Control and Water Conservation District to preserve the 2 to 10-year peak flow rates generated by the project site. Treatment of stormwater runoff through effective BMPs combined with preservation of 2-10 year peak flow rates will ensure target pollutants such as nitrogen and phosphorus are effectively treated and the drainage response is preserved. This strategy will effectively provide a similar level of mitigation required by hydromodification.
6. Hydromodification BMPs are designed to release stored volume over an extended period which effectively increases the duration of low flows. Increasing durations will expand the wet weather

response and could contribute to dry weather flow volume, thereby contributing to dry weather flows. This could conflict with the effort to reduce dry weather input of nitrogen and phosphorus to the estuary. The proposed hydromodification exemption could serve to minimize these potential adverse impacts.

7. Other contributors such as lateral inputs and tidal exchange will not be impacted by the hydromodification exemption. The agricultural fields near the Santa Margarita River Estuary have been identified as a significant source of sediment and nutrients from erosion and subsequent sedimentation in the estuary. Additionally, lack of tidal exchange has been identified as contributing to lower levels of dissolved oxygen. These contributing factors will not be exacerbated from a hydromodification exemption.

These findings strongly support the determination that a hydromodification exemption will not contribute to further degradation of the Santa Margarita River Estuary. The condition of the estuary and the stability of the Santa Margarita River will continue to be monitored and ongoing evaluations will continue as permits are reissued to verify the river is stable.

4.4 Temecula Creek

The extents of the Temecula Creek (Upstream Limit: Outflow of Vail Lake; Downstream Limit: Confluence with Santa Margarita River) for which hydromodification assessment is performed is shown in Figure 4-5.

On September 14, 2017, a field team from Geosyntec investigated segments along Temecula Creek to assess channel stability and susceptibility to erosion, and hydromodification impacts. An initial desktop assessment of aerial maps was used to determine areas of interest showing signs of erosion or geomorphic change. Information was collected based on Hydromodification Screening Tools: Field Manual for Assessing Channel Susceptibility (Booth et al., 2010).

Although multiple locations along the creek were visited, this report is focused on the downstream reach of Temecula Creek, particularly between Pechanga Parkway, at the downstream end, and Avenida de Missiones, at the upstream end. Aerial and field photographs are presented below to highlight observed susceptibility to erosion in the Creek.

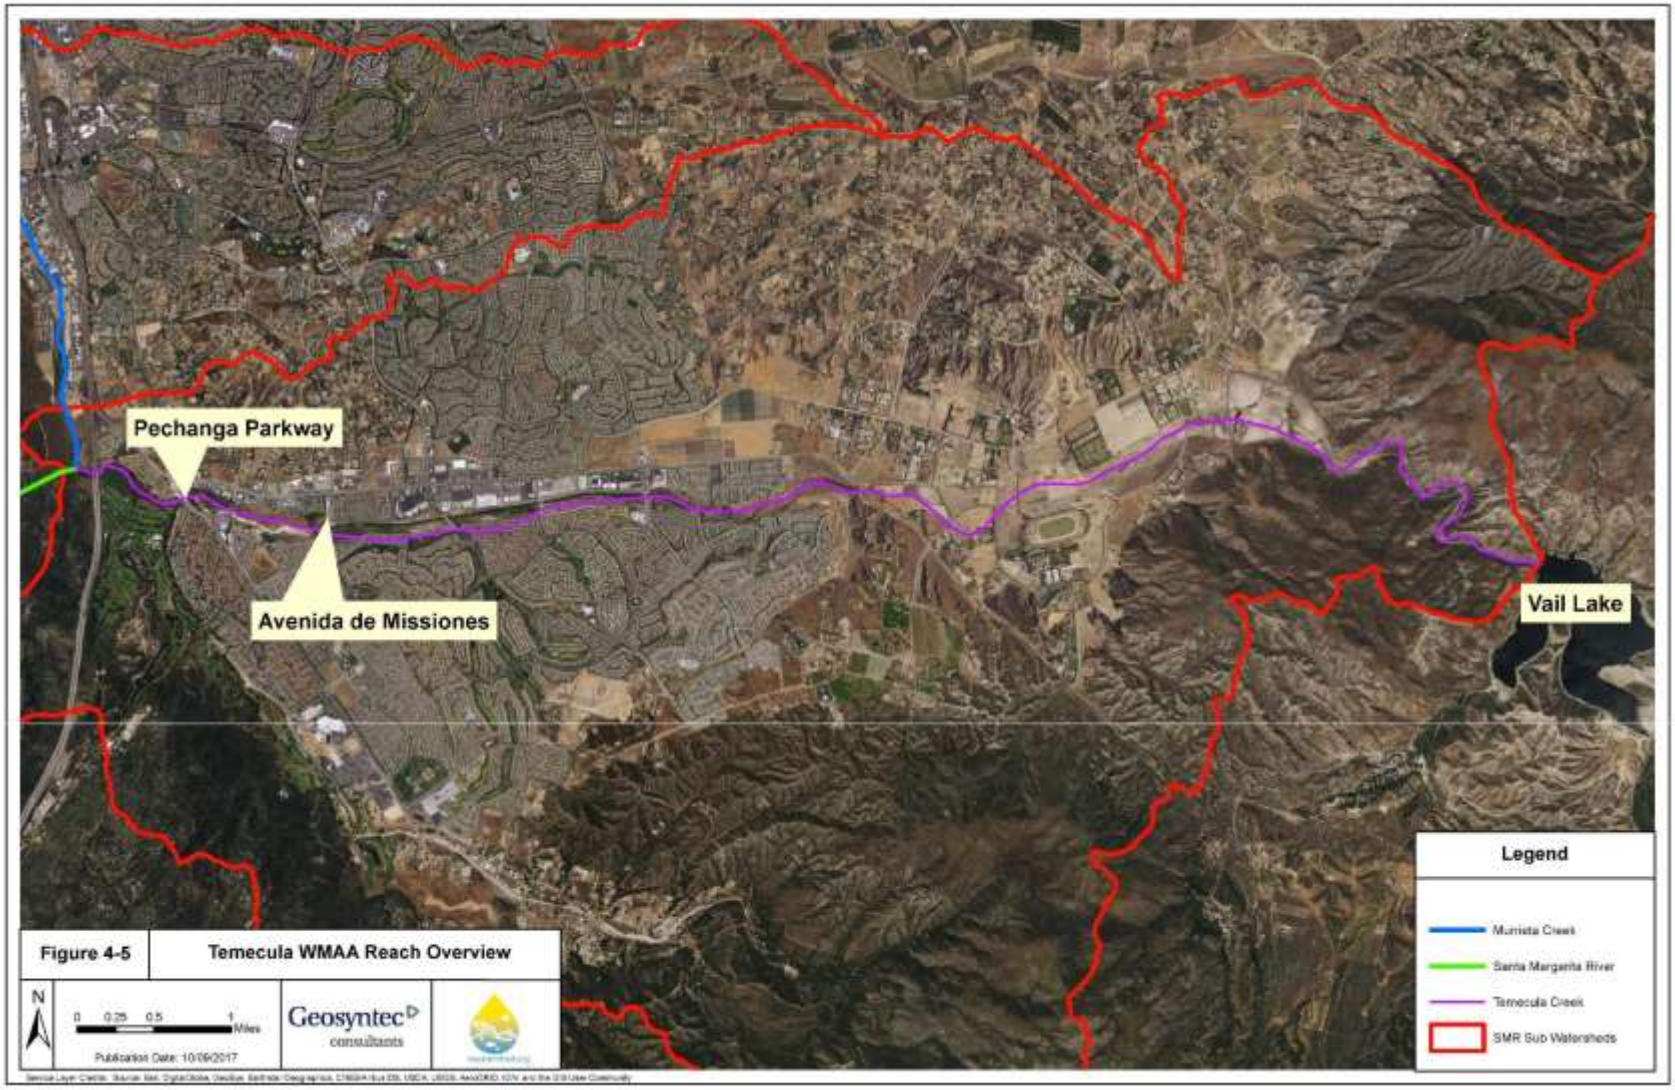

Figure 4-7.: Temecula WMAA Reach Overview

4.4.1 Temecula Creek between Pechanga Parkway and Avenida de Missiones

This segment of Temecula Creek was observed to be wide and heavily vegetated in parts; however, the main portion of the Creek that handles flows was deeply incised at points, with eight-to-nine-foot vertical cuts, soft banks, and a sandy bed. The historical aerials below (Figures 4-6 to 4-11) demonstrate how the channel planform has changed since 1995, and particularly show how concentrated flow has affected the channel form. Field photographs from September 14, 2017 (Figures 4-12 to 4-15) provide documentation of current conditions within the channel.

Figure 4-6 shows Temecula Creek upstream of Pechanga Parkway in late 1995. Per historical aerials, development of the Redhawk community was partially complete by this point, and development of a small residential neighborhood on Temecula Parkway between Country Glen Way and Avenida De Missiones was complete (partially shown in the top-right corner of Figure 4-6). The majority of the remainder of the upstream watershed was not yet developed, though some grading along the north bank of the Creek had begun.

The yellow arrow on the left side of Figure 4-6 shows a drainage lateral to the Creek. Subsequent aerial photos show the lateral enlarging and the effect on Temecula Creek is noticeable. For example, Figure 4-9 shows the Creek in January 2006, after this storm drain channel appears to have been completed. The Creek bed has widened substantially at this confluence and threatens the integrity of the adjacent parking lot. This area is circled in yellow on the left of Figures 4-6 to 4-11.

The yellow circle in the middle of Figure 4-6 shows Creek adjustment near a park on the south bank. This geomorphic adjustment appears to threaten to the structural integrity of the adjacent park.

The yellow arrow on the right side of Figure 4-6 shows the concentrated flow path for upstream flows in the Creek, including flows coming from the Country Glen Way development. Over time, as demonstrated in subsequent aerial photos, the flow path in this portion of Temecula Creek has adjusted. The Creek at this point becomes incised, with eroded vertical banks along the southern bank of the Creek. In addition, the southern bank of the Creek grows wider over time, and gets nearer and nearer to Strawberry Tree Lane.

Figure 4-17. Temecula Creek at Pechanga Parkway, September 2017. Vertical cuts along the north bank of the Creek. Exposed tree roots shown

4.4.2 Recommendation

Based on the historical aerial photo review and field investigation conducted by Geosyntec staff, the downstream end of Temecula Creek is susceptible to erosion. Aerial photographs demonstrate a widening of flow path over the past 20 years. The field investigation observed soft, unconsolidated sand bed material and eroded channel banks, some of which threaten the physical integrity of infrastructure along the southern bank between Pechanga Parkway, at the downstream end, and Via Del Coronado, at the upstream end (e.g., parking lot, park with soccer field, and Strawberry Tree Lane). (Note: The calculations described in Section 4.2 only apply to channels that are stable in present condition; therefore, no calculations are provided for this reach of Temecula Creek being analyzed.)

In light of the creek's susceptibility to erosion and existing infrastructure concerns associated with geomorphic adjustment, it is recommended that the hydromodification exemption not be reinstated at this time. Temecula Creek can be considered a potential candidate for an in-stream restoration/stabilization project to remedy current stability issues and manage for future hydromodification effects associated with new development in its tributary watershed.

4.4.3 Murrieta Creek

The extents of the Murrieta Creek (Upstream Limit: 850 feet upstream of Hawthorn Street; Downstream Limit: Confluence with Santa Margarita River) for which hydromodification assessment is performed is shown in Figure 4-16. Section 4.5.1 presents an overview of the Murrieta Creek Flood Control, Environmental Restoration and Recreation Project.

Figure 4-18: Murrieta WMAA Reach Overview

4.4.4 Murrieta Creek Flood Control, Environmental Restoration and Recreation Project

Murrieta Creek traverses the cities of Temecula and Murrieta in the densely populated southwest region of Riverside County. At the confluence with Temecula Creek, it forms the Santa Margarita River which flows through Camp Pendleton Marine Base and on to the Pacific Ocean. As a result of repeated flood events, culminating with the catastrophic flood in 1993, the U.S. Army Corps of Engineers initiated a study on a 7.5-mile section of the creek, which led to the 2000 Congressional recognition of the 4-phase Murrieta Creek Flood Control, Environmental Restoration and Recreation Project.

The project is anticipated to:

- Improve flood control and storm water retention
- Enhance water conservation and supply
- Provide recreation-related opportunities along the Santa Margarita River and its tributaries in Riverside and San Diego counties

Flood Control Features include:

- Widening and deepening of Murrieta Creek from the USGS stream gauge in Temecula to Tenaja Road in Murrieta
- A flood control detention basin occupying approximately 250 acres on the eastern side of Murrieta Creek between Santa Gertrudis Channel to approximately 500 feet upstream of the confluence with Warm Springs Creek and bordering Adams Avenue, Cherry Street and Jefferson Avenue
- Stream bank protection features between Rancho California Road and First Street

Locally Funded Recreation Features include:

- Construction of a public park of about 50 acres in size within the easternmost portion of the detention basin. This will include parking lot, children's play area, shade structures, comfort station, barbecues, open space, walks, baseball and soccer fields, security lighting, pedestrian/bicycle/equestrian bridges spanning Santa Gertrudis Creek and Murrieta Creek
- Bicycle and equestrian/hiking trails along the eastern and western park in the detention basin, with undercrossing structures beneath the bridges on First Street, Rancho California Road, Winchester Road, Guava Street and Ivy Street

Environmental Restoration Features include:

- Constructing a low flow channel with natural backwaters
- Creating a transitional wetland habitat from freshwater marsh habitat to willow riparian woodland with an upland buffer of mulefat scrub and coastal sage scrub within a 163 acre site
- A 13.7 acre sediment catchment area at the confluence of Murrieta and Warm Springs Creeks

The four phases of the project are shown in Figure 4-17. Phase 1 construction is complete. Phase 2 construction is anticipated to be complete by January 2018. Typical existing and proposed cross section for phase 2 is shown in Figure 4-18.

Figure 4-19. Murrieta Creek Flood Control, Environmental Restoration and Recreation Project

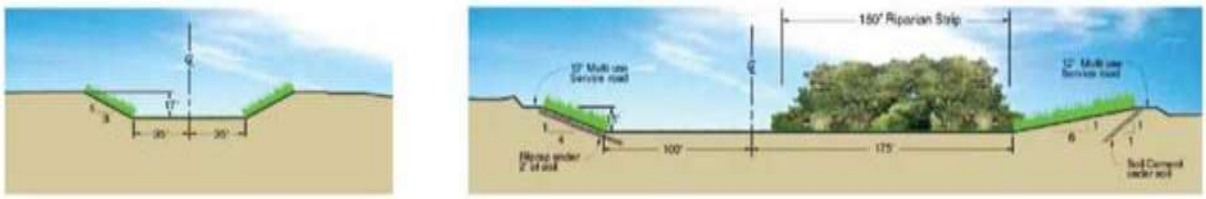

Figure 4-20. Typical existing and proposed cross section for Phase 2

Based on the field visit and assessment conducted by Geosyntec staff on September 14, 2017 the existing phase 3 reach is stable (see Figure 4-19). In the Phase 4 area, walking from downstream to upstream the first sign of erosion was observed at around 80 feet upstream of Washington Avenue (see Figure 4-20).

Figure 4-21. Looking downstream near the Murrieta Creek and Santa Gertrude Creek confluence. Heavily vegetated channel bed and concrete side slope.

Figure 4-22. Looking towards east riverbank 80 feet upstream of Washington Avenue overpass. Sandy gravel riverbanks showing a 25 foot high erosion cut.

Based on the findings from the field visit and consideration of the ongoing Phase 2 of the Murrieta Creek Flood Control, Environmental Restoration and Recreation Project that is anticipated to be complete by

January 2018, the exemption analysis extents were revised for Murrieta Creek (Upstream Limit: Washington Avenue; Downstream Limit: Confluence with Santa Margarita River). The same approach that was used for Forester Creek (engineered channels that are stabilized with materials other than concrete, such as riprap, turf reinforcement mat, or vegetation) as part of the San Diego River WQIP was implemented for Murrieta Creek and summarized below.

4.4.5 Erosion Potential Analysis

See section 4.2.1 for a description of the entire erosion potential analysis. This section includes specific information on erosion potential in the extents of the Murrieta Creek:

The following steps were implemented to estimate the Erosion Potential:

- The table below presents the input parameters used to construct flow histograms. The critical slope and cross-section was obtained from Phase 2 design plans.

Stabilized Conveyance System	Area below the reservoirs/lakes (sq. miles)	Mean Annual Precipitation (in)	Length of Daily Flow Record (Years)	Channel Slope (ft/ft)
Murrieta Creek	149	14.7	30	0.002

- The critical cross section was based on the narrowest cross section (140 feet wide trapezoidal channel) and the steepest slope (0.2% longitudinal slope) in the phase 2 plans.
- Critical shear stress was estimated to be greater than or equal to 1.2 pounds per square foot (lb/ft2), based on review of permissible shear stress values presented in "Stability Thresholds for Stream Restoration Materials" (Fischenich 2001) and "Streambank Soil Bioengineering Considerations for Semi-Arid Climates" (Hoag and Fripp 2005). Based on Fischenich 2001, permissible shear stress for "long native grasses" is approximately 1.2 to 1.7 lb/ft2. The side slopes are generally either turn reinforcement mat, soil cement protection, rip-rap or dense vegetation all of which have critical shear stress greater than or equal to 8 pounds per square foot (lb/ft2)

Steps 1 to 5 were performed in Excel. Ep estimates for the exempt river reaches are included as an Attachment H. Results from the Ep analysis are summarized in table below.

Stabilized Conveyance System	Area below the reservoirs (Skinner Reservoir) (acres)	Impervious Area (acres) [%]			Ep (Post/Pre)
		Pre (existing)	Post (built out)	Increase	
Murrieta Creek	95,251	13,762 [14.4]	20,634 [21.7]	6872 [7.3]	1

The analysis results, presented in Attachment H, show that for both the existing and future condition, the shear stress for all geomorphically-effective flows is less than the estimated critical shear stress of 1.2 lb/ft^2. This means that no excess shear stress or "work" occurs in the channel in either the existing or future condition. Therefore, there is no increase in the duration of "work" (cumulative work), in the future condition, and erosion potential is 1.0.

Note that while the flow rates are the same in both the existing and future condition analyses, the duration of each flow rate is increased in the future condition. The flow rates in the flow bins are based on the watershed area, mean annual precipitation, and length of the synthetic record. The synthetic record means the modeled or analytically- derived series of hydrology parameters such as flow rate and duration of flow at points or nodes in the system. Available measures parameters such as precipitation, catchment area, catchment slopes, channel conditions, and are used as inputs to the model or algorithm. Watershed area, mean annual precipitation, and length of the synthetic record do not change from existing to future condition. The duration for each flow bin is related to the watershed area, mean annual precipitation, length of the synthetic record, and the impervious area. The duration increases in the future condition based on the increased impervious area. The increase in duration would result in increased cumulative work in the future condition if any of the flow rates resulted in shear stress greater than the estimated critical shear stress (excess shear stress, or "work"), because cumulative work is the product of work times duration.

The scenario that occurred in the Murrieta Creek analysis, in which no work occurred in the expected range of geomorphically-effective flow rates, is a potential scenario for engineered channels because engineered conveyance systems are typically engineered for flood flows much greater and less frequent than the geomorphically-effective flows. For example, Murrieta Creek is being engineered to convey a 100-year flow rate of approximately 30,900 cubic feet per second (cfs) (100-year flow estimate is from FEMA Flood Insurance Study). The maximum geomorphically-effective flow rate for Murrieta Creek is 11,000 cfs.

In addition, the USACE report states that for the Phase 2 design it is anticipated that flows of about seven feet/second and above could cause erosion and scouring of the unmaintained riparian/low-flow corridor. These occurrences of erosion and scour are expected to be within the range of current conditions. It is anticipated that the larger trees would remain in place once established; however, the smaller trees and shrubs may be washed out during significant storm events. Natural recruitment is expected within areas of scour as has occurred within the Phase I area, where riparian and wetland vegetation within the channel invert has re-established after completion of construction. The estimated velocity for the maximum geomorphically-effective flow rate of 11,000 cfs for Murrieta Creek is 5.8 feet/second. This also supports the hydromodification management exemption.

4.4.6 Recommendation

Based on the results from this study, it is recommended that hydromodification management exemption be reinstated for projects discharging runoff directly to the Murrieta Creek (Upstream Limit: Washington Avenue; Downstream Limit: Confluence with Santa Margarita River).

Hydromodification management exemption from Washington Avenue to 850 feet upstream of Hawthorn Street is not reinstated at this time. Based on the field visit and assessment by Geosyntec staff, this segment of channel appeared to be unstable and susceptible to erosion.

4.5 Conclusion

Based on the results from this study, it is recommended that hydromodification management exemption be reinstated for projects discharging runoff directly to the following exempt river reaches:

- Santa Margarita River

- Upstream Limit: At Origin, i.e. Confluence with Temecula Creek and Murrieta Creek
- Downstream Limit: Outfall to Pacific Ocean

- Murrieta Creek
  - Upstream Limit: Washington Avenue
  - Downstream Limit: Confluence with Santa Margarita River

Each municipality must define/approve "direct discharge" based on the project site conditions. To qualify for the potential exemption, the outlet elevation must be between the river bottom elevation and the 100-year floodplain elevation and properly designed energy dissipation must be provided.

4.5.1 Factors of Safety

The analysis conducted to evaluate the applicability of hydromodification management requirements to priority development projects directly discharging to the exempt river reaches have the following implicit factors of safety:

- The analysis assumes all projects within the watershed will be exempt from hydromodification management requirements for erosion potential and coarse sediment supply calculations (note: during actual implementation only projects directly discharging to the exempt reach will be exempt). This conservative assumption provides an implicit (non-quantified) factor of safety.
- The analysis assumes all impervious area in the watershed is directly connected impervious area. In actuality, some portion of these impervious areas will sheet flow through pervious areas prior to discharging to the streams. This dispersion will result in attenuation of flow rates and durations that are not accounted for when estimating the sediment transport capacity of the built-out condition. This conservative assumption provides an implicit (non-quantified) factor of safety.
- New priority development projects, including projects that are proposed to be exempt from hydromodification management requirements through this study, must implement retention BMPs to the extent feasible if participation in alternative compliance is not selected or allowed. This requirement will result in attenuation of flow rates and durations that are not accounted for when estimating the sediment transport capacity of the built-out condition. This conservative assumption provides an implicit (non-quantified) factor of safety.
- Redevelopment priority development projects in the watershed that do not directly discharge to the river reach that is exempt by this study must mitigate flows to the pre-developed condition. This will result in over mitigation of flow rates and durations for redevelopment projects which are not accounted for when estimating the sediment transport capacity of the built-out condition. This conservative assumption provides an implicit (non-quantified) factor of safety.

4.5.2 Limitations

The analysis and associated recommendations as presented above were based on instream erosion as the primary consideration to support reinstatement of exemptions from hydromodification management controls for discharges directly to these river reaches. While it is recognized that other factors contribute to adverse impacts (e.g., salinity imbalance, pollutants) to instream habitat and resulting biotic integrity, hydromodification management control has traditionally been considered an "umbrella process" that encompasses most of the highest risk stressors (percent sands and fines present, channel alteration, and riparian disturbance) to physical habitat.

The current assessment methods may yield inconclusive results when attempting to identify causal relationships between degraded instream habitat solely due to increased flows and erosive force from hydromodification. A causal assessment recently conducted in the lower reaches of the San Diego River, conducted as a partnership between the Southern California Coastal Water Research Project (SCCWRP), the City of San Diego, the County of San Diego, and the San Diego RWQCB, focused on stressors potentially responsible for known biological impairment of the river. Once the data of the causal assessment become available, it may be useful in classifying the potential stressors such as altered physical habitat as likely, unlikely, or an uncertain cause to biological impairment.

With respect to adverse impacts to habitat as a result of pollutants entrained in storm water discharges, these areas will still be subject to the pollutant control requirements of the Regional MS4 Permit as areas develop or redevelop. The current requirements require development to maximize retention of the design storm volume which will mitigate a portion of the volume that would otherwise be controlled with hydromodification management BMPs. In some cases, this offsetting of volume reduction through pollutant control BMPs may exceed the HMP volumes. In addition, the development that occurs within the exempted watershed areas is still required to provide any applicable flood control measures. Risk of flooding as a result of exemption from hydromodification controls is unlikely as the control thresholds are significantly lower (order of magnitude) than flood control requirements implemented to protect life and property.

5 Conclusions

This WMAA used available regional data to understand watershed-scale characteristics and processes in the SMR. The results of this analysis are shown on the maps in Attachment A. This analysis combined with the San Diego Water Quality Equivalency guidance can be used to provide flexibility with meeting the Permit's land development requirements. The WMAA mapping includes readily available regional datasets and specific projects will be augmented with site-specific analysis. As such, projects will also consult the future BMP Design manual for options to meet the Permit requirements. The Co-Permittees continue to develop the BMP Manual and are looking for additional compliance options for small projects, single-family residences or sites that substantially mimic predevelopment conditions.

7 Glossary

Term	Definition
Alternative Compliance Program	An optional program that may be implemented by individual Co-Permittees to allow for offsite ACPs to offset stormwater pollutant control and hydromodification impacts that are not fully addressed at PDP sites.
Best Management Practice (BMP)	Any procedure or device designed to minimize the quantity of Pollutants that enter the MS4 or to control stormwater flow.
Bioretention	A type of BMP that is designed to capture a certain volume of stormwater within a biologically active soil media. Retained water is evapotranspired by plants in the BMP or allowed to slowly infiltrate into the underlying soils.
Hydromodification	The change in the natural watershed hydrologic processes and runoff characteristics (i.e., interception, infiltration, overland flow, and groundwater flow) caused by urbanization or other land use changes that result in increased stream flows and sediment transport. In addition, alteration of stream and river channels, such as stream channelization, concrete lining, installation of dams and water impoundments, and excessive streambank and shoreline erosion are also considered hydromodification, due to their disruption of natural watershed hydrologic processes.
Municipal Separate Storm Sewer System (MS4)	A conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels or storm drains) as defined in 40 CFR 122.26(b)(8).
Priority Development Project	New development and redevelopment projects defined under Provision E.3.b of the Permit.
Structural BMP	A subset of BMPs which detains, retains, filters, removes, or prevents the release of pollutants to surface waters from development projects in perpetuity, after construction of a project is completed.
Water Quality Improvement Plan (WQIP)	A planning document which describes programs which will be implemented to meet water quality requirements as described in Provision B of the Permit.
Water Quality Equivalency	Methodologies and calculations used to determine water quality benefits and water quality impacts, and to apply them toward the design, review, and approval of PDPs and ACPs in meeting the Section E.3.c.(3) requirements of the Permit.
SMR Co-Permittees	The SMR Co-Permittees include County of Riverside, Riverside County Flood Control and Water Conservation District, City of Wildomar, City of Murrieta, City of Temecula, City of Menifee and County of San Diego.

Potential Critical Coarse Sediment Yield Areas - Santa Magarita River Watershed

Figure B.2

MEMO

TO: Matt Yeager, D.Env, CPSWQ, QSD/P

FROM: Veronica Seyde

SUBJECT: Santa Margarita Watershed Management Area – RUSLE Analysis

DATE: June 29, 2018

INTRODUCTION

A review of the potential critical coarse sediment yield areas within the Santa Margarita watershed management area was conducted as a response to San Diego Regional Water Quality Control Board (San Diego RWQCB) comments. Differences in potential critical coarse sediment yield areas along the county line were noted, focusing within the northeastern portion of the watershed management area (see Exhibit 1). This memo evaluates the critical coarse sediment yield analysis conducted in this area to identify the data sources that were attributable to the final results that indicated these differences.

CRITICAL COARSE SEDIMENT YIELD ANALYSIS

GEOMORPHIC LANDSCAPE UNIT

Critical coarse sediment yield analysis is based on the Geomorphic Landscape Unit (GLU) method described by Booth et al. (2010). GLUs characterize the magnitude of sediment production from areas using three factors judged to exert the greatest influence on the variability of sediment-production rates: geology types, hillslope gradient and land cover. The geologic categories considered to have the potential to generate coarse sediment are coarse bedrock (CB), coarse sedimentary impermeable (CSI) and coarse sedimentary permeable (CSP). Exhibit 2 displays the geologic categories in the Santa Margarita watershed management area. Based on the GIS analysis, the Santa Margarita watershed management area is predominantly characterized with geologic categories that contribute coarse sediment (i.e., CB, CSI and CSP). Once the GLUs were identified, they were then evaluated to determine their relative sediment production to identify potential critical coarse sediment yield areas.

RELATIVE SEDIMENT PRODUCTION

Relative sediment production is estimated for each GLU using the Revised Universal Soil Loss Equation (RUSLE) (see Equation 2).

$$A = R \times K \times LS \times C \times P \quad \text{(Equation 2), where}$$

A = estimated average soil loss in tons/acre/year

R = rainfall-runoff erosivity factor

K = soil erodibility factor

LS = slope length and steepness factor

C = cover-management factor

P = support practice factor; assumed 1 for this analysis

An area that is identified as CB, CSI or CSP coupled with a relative RUSLE rate of High is considered as a potential critical coarse sediment yield area.

Evaluation of the K, LS and C factors indicated that the results along the San Diego and Riverside county border are similar. The P factor results are also similar because this factor was assumed as equal to 1 for both the San Diego County and Riverside County analyses. Although the same public domain data sources were used for these data sets, among the five data sets, it was noted that the R factor, or the rainfall-runoff erosivity factor[1], was attributable to the difference in critical coarse sediment yield areas along the county border (See Exhibit 3).

For the Santa Margarita watershed management area in San Diego County, a broad approach was used where one R value was assigned for each GLU by estimating the area weighted number. For example, a R value of 30 was assigned if a GLU was located between the 40 and 20 isoerodent contours (see Exhibit 3, Figure 3.A). Whereas, for the study area in Riverside County, the R factor varies spatially by using specific available R value isoerodent contour data, resulting in a very fine resolution R value (see Exhibit 3, Figure 3.A, Figure 3.B and Figure 3.C).

These area resolution differences among the R factor data along the county border resulted in identified differences in potential critical coarse sediment yield areas. These differences are solely due to the broad assumption method versus the use of specific contour data.

[1] The R factor is the total storm kinetic energy (E) times the maximum 30-minute intensity (I30). The numerical value of R is the average annual sum of EI30 for storm events during a rainfall record of at least 22 years.

BORDER PROJECTS

The potential critical coarse sediment yield analysis utilized regional, public domain datasets and provided a useful, rapid framework to perform a screening level analysis for the Santa Margarita watershed management area. This mapping effort essentially provided a high-level analysis to provide informed decision making at a regional-scale. Because of the regional-scale datasets, and commensurate data resolution used to map the potential critical coarse sediment yield areas, some areas may have been mapped that do not produce critical coarse sediment as they are existing developed areas. Furthermore, the analysis did not consider instream sediment supply or fire-induced sediment production (Lave and Burbank 2004). In addition, the resolution differences among the R-factor data resulted in differences in potential critical coarse sediment yield areas along the county border. Given the GLU characteristics in the watershed, however, a further evaluation of hydrologic soil groups and sand and gravel deposits along the border and in the northeastern portion of the watershed was performed.

GRAVEL AND SAND DEPOSITS

To verify the differences in potential critical coarse sediment yield areas along the county border, an evaluation of hydrologic soil groups (HSG) and gravel and sand deposits was conducted. HSG type A and type B soils are considered sands, gravelly sands and coarse textured soils which would contribute coarse sediment. The custom HSG report for the study area along the border indicated that only 22 percent of the soil material in this area was considered as deep, well drained to excessively well drained sands or gravelly sands (HSG A) or moderately well drained soils that have moderately fine texture to moderately coarse texture (HSG B) (Natural Resources Conservation Service 2018). Of special interest is the area in the northeastern part of the watershed. According to the HSG report, this area is predominated by HSG type D soils and would therefore not be expected to exhibit the characteristics associated with a coarse sediment yield area. The HSG reports generated for this evaluation are provided as a Supplemental Attachment.

Another line of evidence to support potential critical coarse sediment areas was provided by evaluating United States Geological Survey mineral resource maps online (USGS 2018). Based on the area of interest along the border, there are no sand and gravel deposits within a 2-mile radius north and south of the border. Sand and gravel deposits, however, were noted in areas generally downstream of CB, CSI, and CSP geologic units. These deposits were therefore considered as an area that may be a potential sediment source area and it was decided that further evaluation was warranted.

The identification of potential sediment source areas was determined using the following process:

- Overlay sand/gravel deposits onto Geology Grouping GIS layer
- Using USGS quad maps, identify the tributary drainage area for each deposit located in a CB, CSI or CSP area
- Exclude the following areas:
    - Agricultural Land
    - Developed Land
    - Non-Permittee Area
        - Camp Pendleton
    - Protected Lands

The resulting GIS map showing the spatial distribution of the potential critical coarse sediment yield areas along with potential sediment source areas within the SMR is provided as Exhibit 4.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at scales ranging from 1:15,800 to 1:24,000.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL:
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: San Diego County Area, California
Survey Area Data: Version 12, Sep 13, 2017

Soil Survey Area: Western Riverside Area, California
Survey Area Data: Version 10, Sep 12, 2017

Your area of interest (AOI) includes more than one soil survey area. These survey areas may have been mapped at different scales, with a different land use in mind, at different times, or at different levels of detail. This may result in map unit symbols, soil properties, and interpretations that do not completely agree across soil survey area boundaries.

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Dec 31, 2009—Feb 2, 2017

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

Rating Options

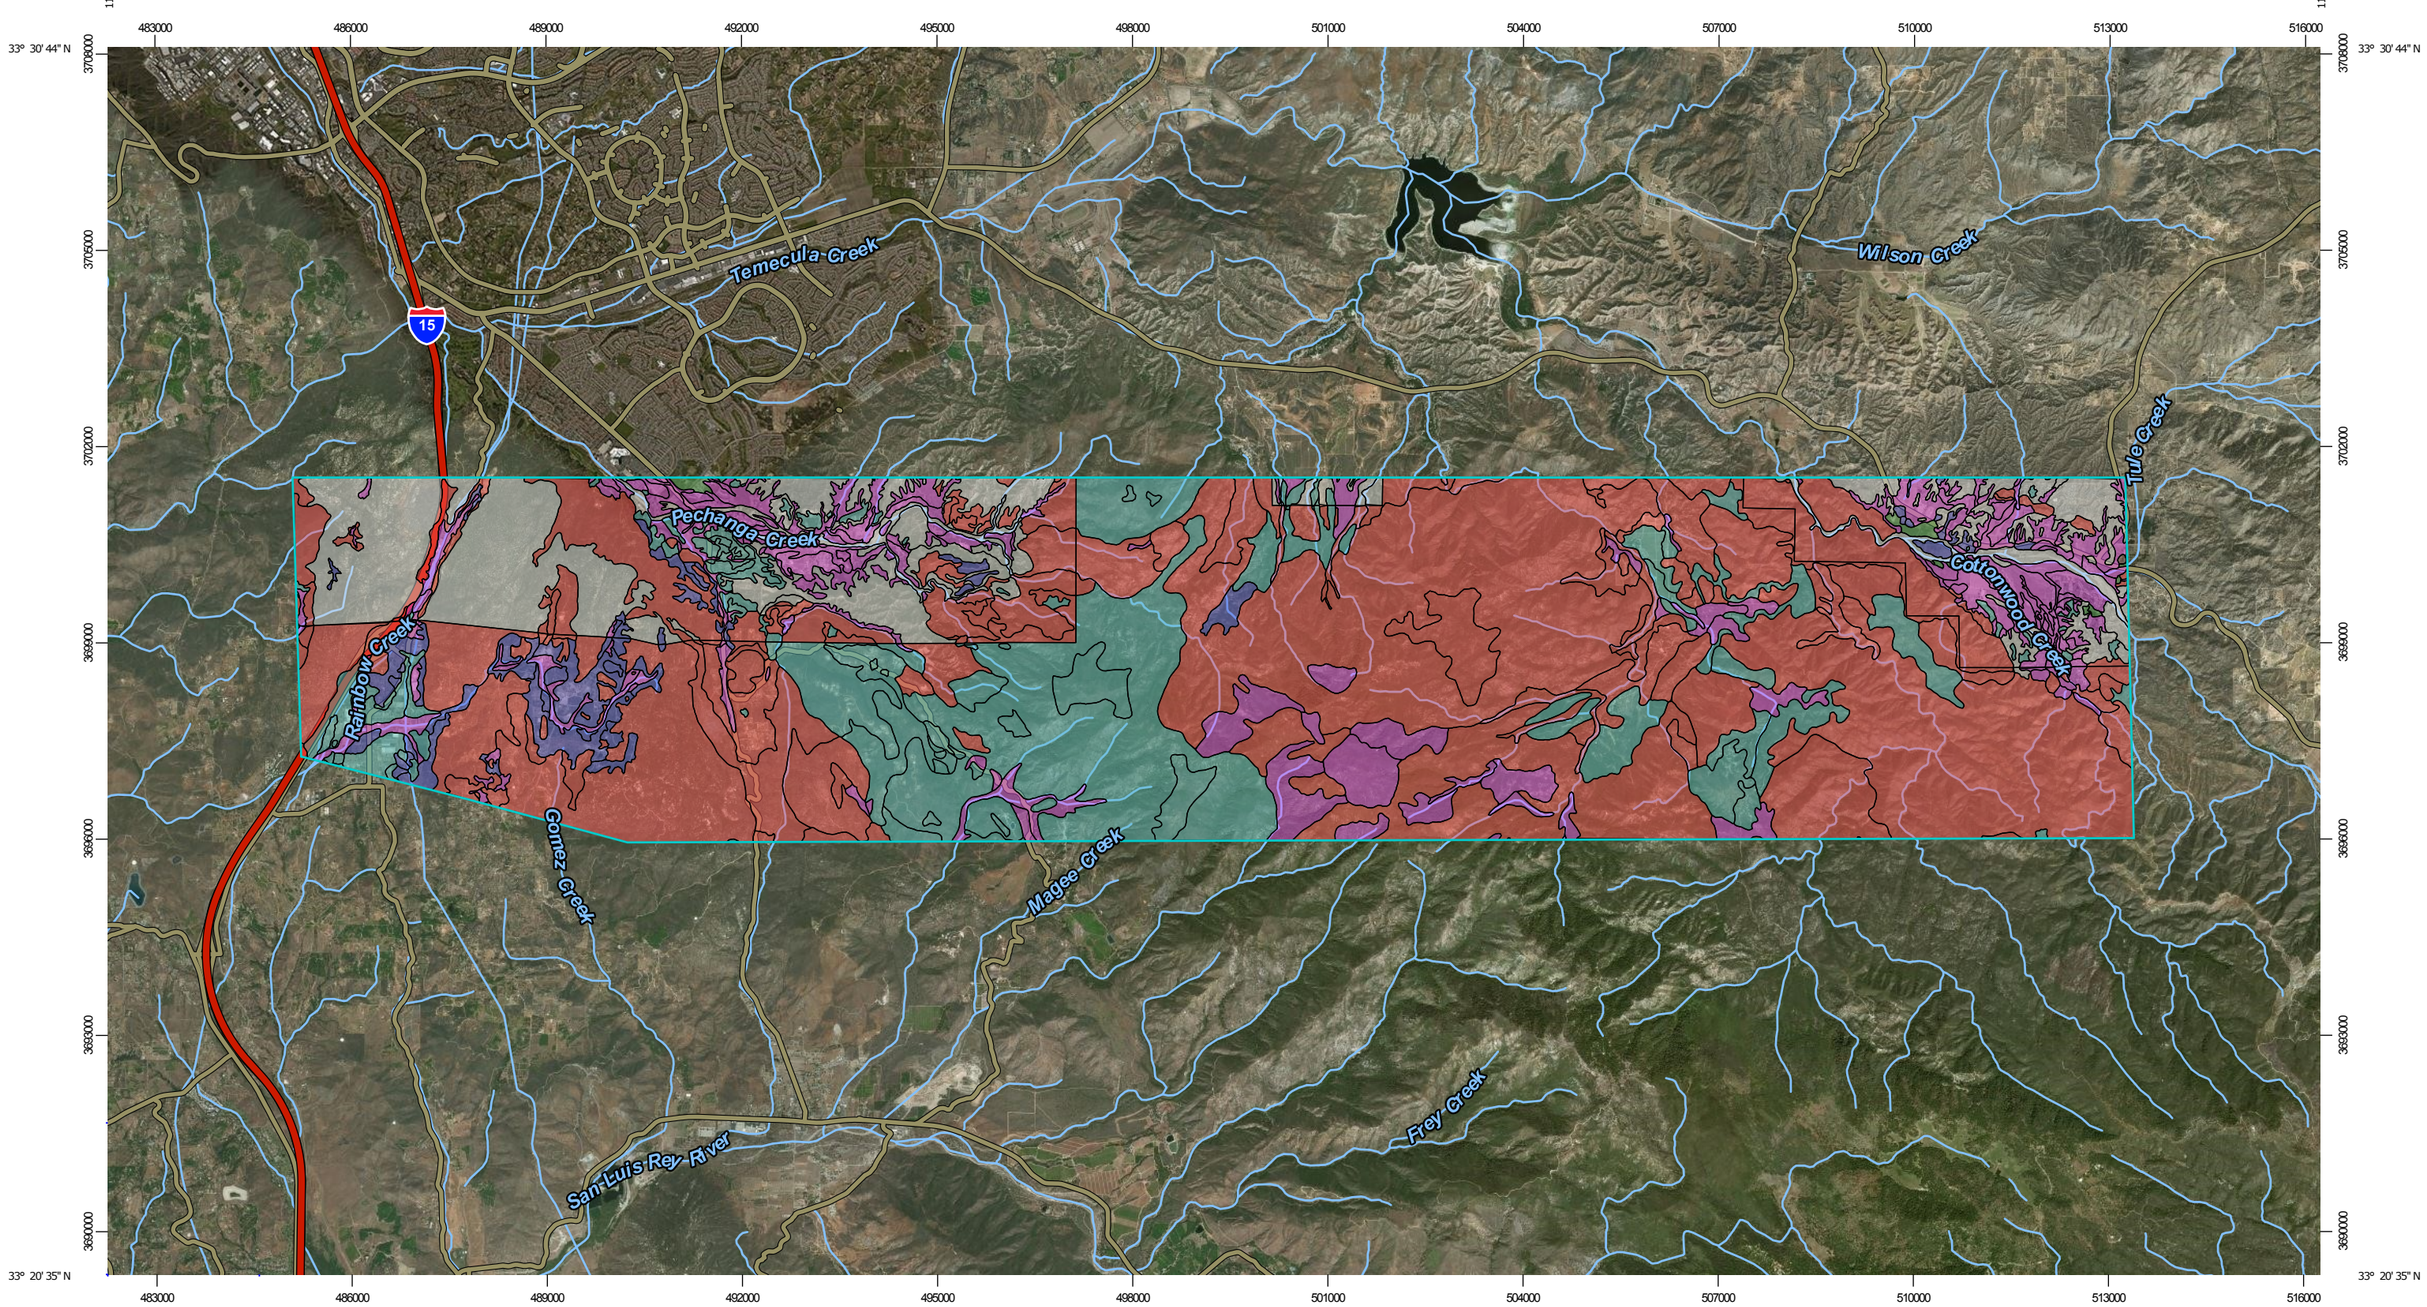
Aggregation Method: Dominant Condition

Aggregation is the process by which a set of component attribute values is reduced to a single value that represents the map unit as a whole.

A map unit is typically composed of one or more "components". A component is either some type of soil or some nonsoil entity, e.g., rock outcrop. For the attribute being aggregated, the first step of the aggregation process is to derive one attribute value for each of a map unit's components. From this set of component attributes, the next step of the aggregation process derives a single value that represents the map unit as a whole. Once a single value for each map unit is derived, a thematic map for soil map units can be rendered. Aggregation must be done because, on any soil map, map units are delineated but components are not.

For each of a map unit's components, a corresponding percent composition is recorded. A percent composition of 60 indicates that the corresponding component typically makes up approximately 60% of the map unit. Percent composition is a critical factor in some, but not all, aggregation methods.

The aggregation method "Dominant Condition" first groups like attribute values for the components in a map unit. For each group, percent composition is set to the sum of the percent composition of all components participating in that group. These groups now represent "conditions" rather than components. The attribute value associated with the group with the highest cumulative percent composition is returned. If more than one group shares the highest cumulative percent composition, the corresponding "tie-break" rule determines which value should be returned. The "tie-break" rule indicates whether the lower or higher group value should be returned in the case of a percent composition tie. The result returned by this aggregation method represents the dominant condition throughout the map unit only when no tie has occurred.



Component Percent Cutoff: None Specified

Components whose percent composition is below the cutoff value will not be considered. If no cutoff value is specified, all components in the database will be considered. The data for some contrasting soils of minor extent may not be in the database, and therefore are not considered.

Tie-break Rule: Higher

The tie-break rule indicates which value should be selected from a set of multiple candidate values, or which value should be selected in the event of a percent composition tie.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at scales ranging from 1:15,800 to 1:24,000.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL:
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: San Diego County Area, California
Survey Area Data: Version 12, Sep 13, 2017

Soil Survey Area: Western Riverside Area, California
Survey Area Data: Version 10, Sep 12, 2017

Your area of interest (AOI) includes more than one soil survey area. These survey areas may have been mapped at different scales, with a different land use in mind, at different times, or at different levels of detail. This may result in map unit symbols, soil properties, and interpretations that do not completely agree across soil survey area boundaries.

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Dec 31, 2009—Feb 2, 2017

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

Rating Options

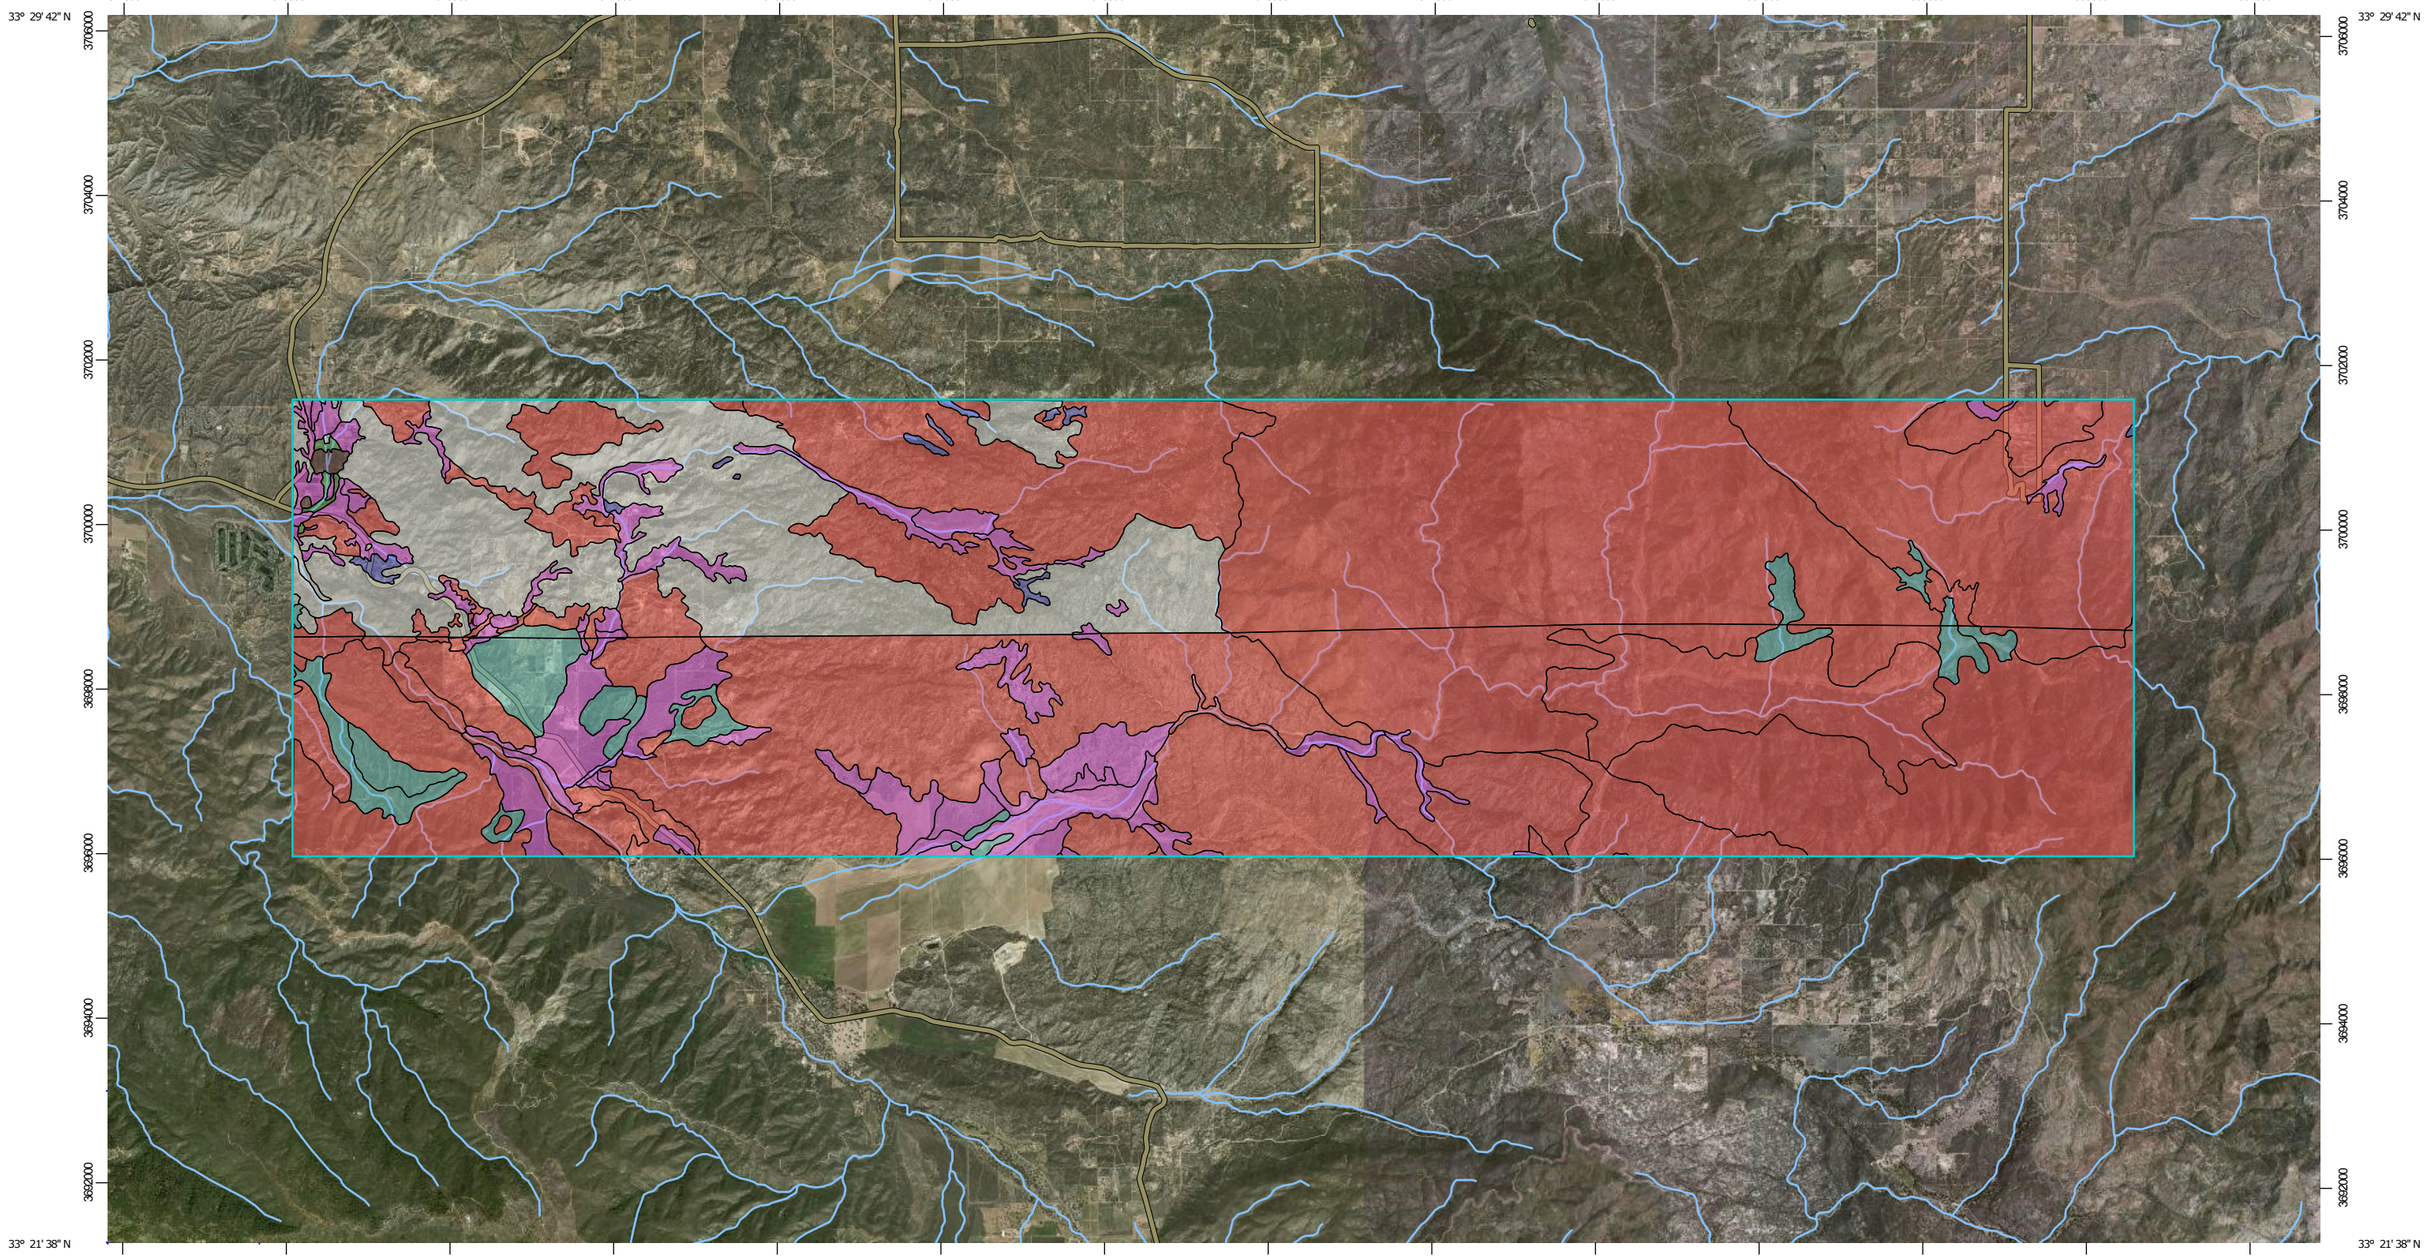
Aggregation Method: Dominant Condition

Aggregation is the process by which a set of component attribute values is reduced to a single value that represents the map unit as a whole.

A map unit is typically composed of one or more "components". A component is either some type of soil or some nonsoil entity, e.g., rock outcrop. For the attribute being aggregated, the first step of the aggregation process is to derive one attribute value for each of a map unit's components. From this set of component attributes, the next step of the aggregation process derives a single value that represents the map unit as a whole. Once a single value for each map unit is derived, a thematic map for soil map units can be rendered. Aggregation must be done because, on any soil map, map units are delineated but components are not.

For each of a map unit's components, a corresponding percent composition is recorded. A percent composition of 60 indicates that the corresponding component typically makes up approximately 60% of the map unit. Percent composition is a critical factor in some, but not all, aggregation methods.

The aggregation method "Dominant Condition" first groups like attribute values for the components in a map unit. For each group, percent composition is set to the sum of the percent composition of all components participating in that group. These groups now represent "conditions" rather than components. The attribute value associated with the group with the highest cumulative percent composition is returned. If more than one group shares the highest cumulative percent composition, the corresponding "tie-break" rule determines which value should be returned. The "tie-break" rule indicates whether the lower or higher group value should be returned in the case of a percent composition tie. The result returned by this aggregation method represents the dominant condition throughout the map unit only when no tie has occurred.



Component Percent Cutoff: None Specified

Components whose percent composition is below the cutoff value will not be considered. If no cutoff value is specified, all components in the database will be considered. The data for some contrasting soils of minor extent may not be in the database, and therefore are not considered.

Tie-break Rule: Higher

The tie-break rule indicates which value should be selected from a set of multiple candidate values, or which value should be selected in the event of a percent composition tie.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at scales ranging from 1:15,800 to 1:24,000.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL:
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: San Diego County Area, California
Survey Area Data: Version 12, Sep 13, 2017

Soil Survey Area: Western Riverside Area, California
Survey Area Data: Version 10, Sep 12, 2017

Your area of interest (AOI) includes more than one soil survey area. These survey areas may have been mapped at different scales, with a different land use in mind, at different times, or at different levels of detail. This may result in map unit symbols, soil properties, and interpretations that do not completely agree across soil survey area boundaries.

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Dec 31, 2009—Feb 2, 2017

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

Aggregation Method: Dominant Condition

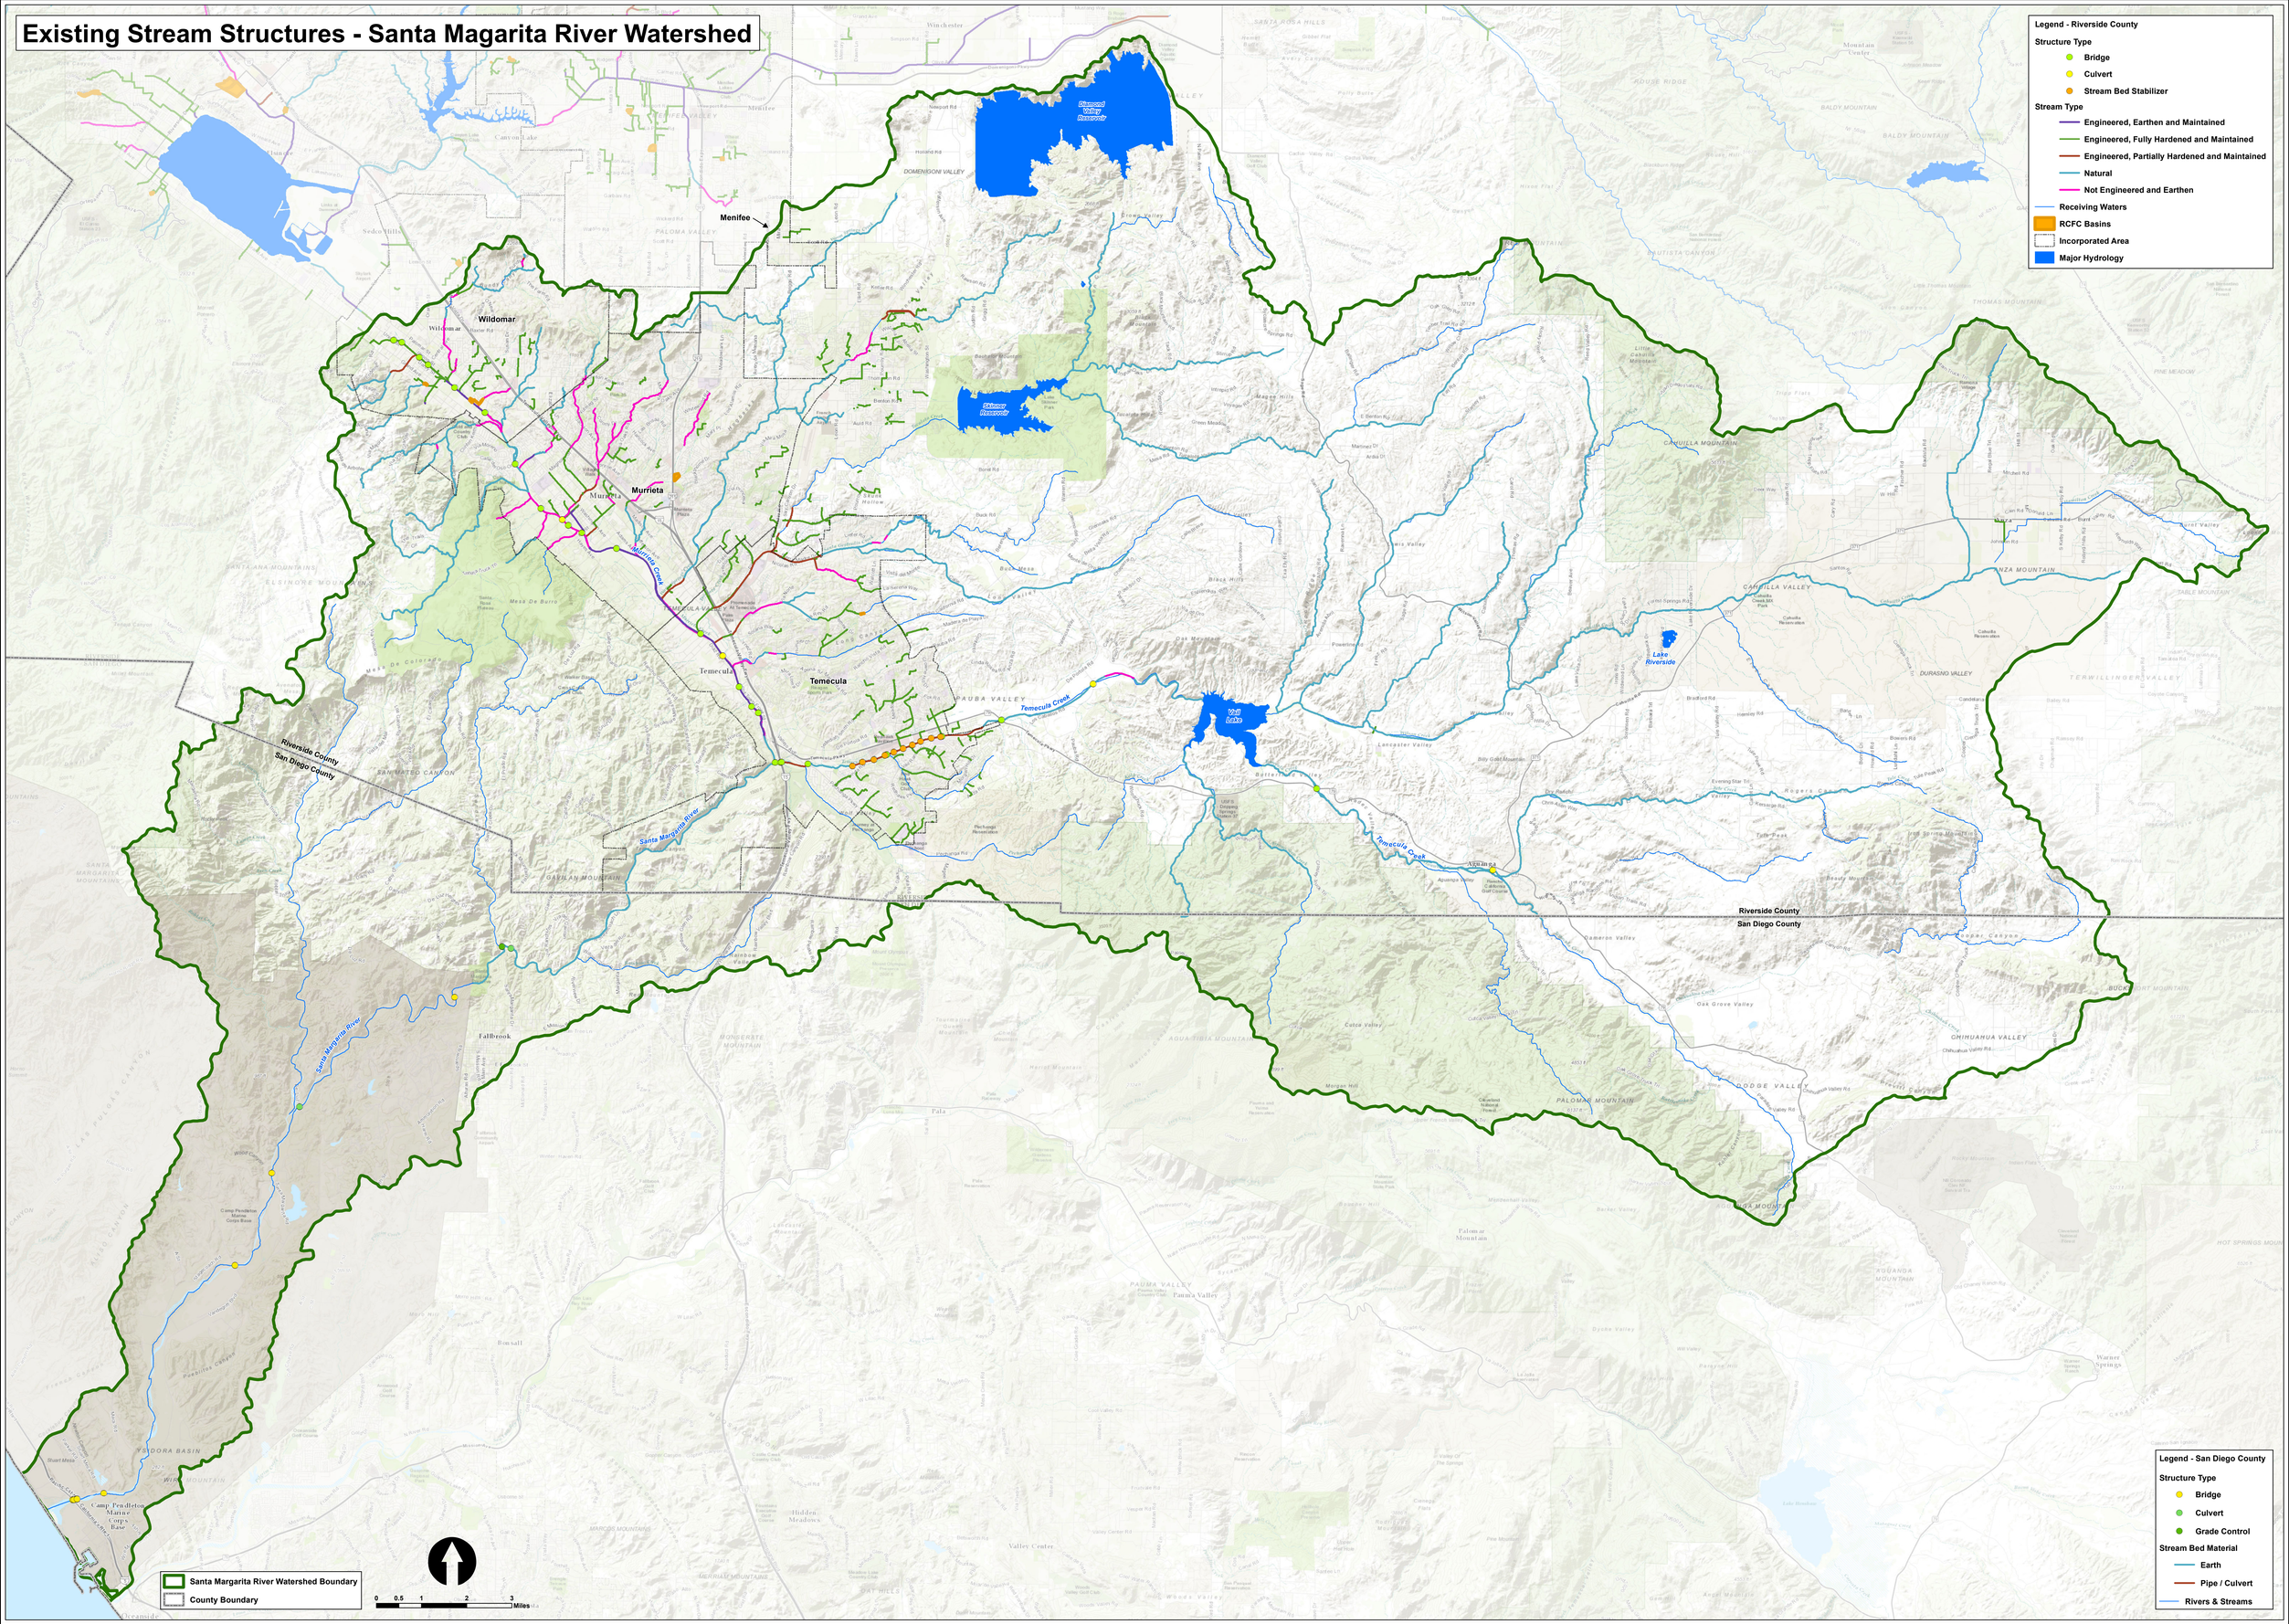
Aggregation is the process by which a set of component attribute values is reduced to a single value that represents the map unit as a whole.

A map unit is typically composed of one or more "components". A component is either some type of soil or some nonsoil entity, e.g., rock outcrop. For the attribute being aggregated, the first step of the aggregation process is to derive one attribute value for each of a map unit's components. From this set of component attributes, the next step of the aggregation process derives a single value that represents the map unit as a whole. Once a single value for each map unit is derived, a thematic map for soil map units can be rendered. Aggregation must be done because, on any soil map, map units are delineated but components are not.

For each of a map unit's components, a corresponding percent composition is recorded. A percent composition of 60 indicates that the corresponding component typically makes up approximately 60% of the map unit. Percent composition is a critical factor in some, but not all, aggregation methods.

The aggregation method "Dominant Condition" first groups like attribute values for the components in a map unit. For each group, percent composition is set to the sum of the percent composition of all components participating in that group. These groups now represent "conditions" rather than components. The attribute value associated with the group with the highest cumulative percent composition is returned. If more than one group shares the highest cumulative percent composition, the corresponding "tie-break" rule determines which value should be returned. The "tie-break" rule indicates whether the lower or higher group value should be returned in the case of a percent composition tie. The result returned by this aggregation method represents the dominant condition throughout the map unit only when no tie has occurred.

Component Percent Cutoff: None Specified



Components whose percent composition is below the cutoff value will not be considered. If no cutoff value is specified, all components in the database will be considered. The data for some contrasting soils of minor extent may not be in the database, and therefore are not considered.

Tie-break Rule: Higher

The tie-break rule indicates which value should be selected from a set of multiple candidate values, or which value should be selected in the event of a percent composition tie.

APPENDIX H…….... POTENTIAL SEDIMENT SOURCE AREA EXHIBIT

1 INTRODUCTION

The Western Riverside Council of Governments (WRCOG) comprises the County of Riverside and each city located within Western Riverside County. WRCOG was established to provide an agency to conduct studies and projects designed to improve and coordinate the common governmental responsibilities and services on an area-wide and regional basis. Some of the functions performed by WRCOG include serving as a forum for consideration, study and recommendation on area-wide regional problems; assembling information helpful in the consideration of problems peculiar to Western Riverside County; exploring practical avenues for intergovernmental cooperation, coordination and action in the interest of local public welfare and means of improvements in the administration of governmental services; and serving as the clearinghouse review body for Federally-funded projects in conjunction with the Southern California Association of Governments[1]. To this end, and in the spirit of respecting local control while providing a regional perspective, WRCOG is collaborating with the Riverside County Flood Control and Water Conservation District (RCFCWCD) for the development of a Watershed Management Area Analysis (WMAA) of the upper Santa Margarita River watershed which is under the jurisdiction of the San Diego Regional Water Quality Control Board (RWQCB). An exhibit that displays these jurisdictional boundaries as they relate to the Santa Margarita River watershed is provided as Figure 1.

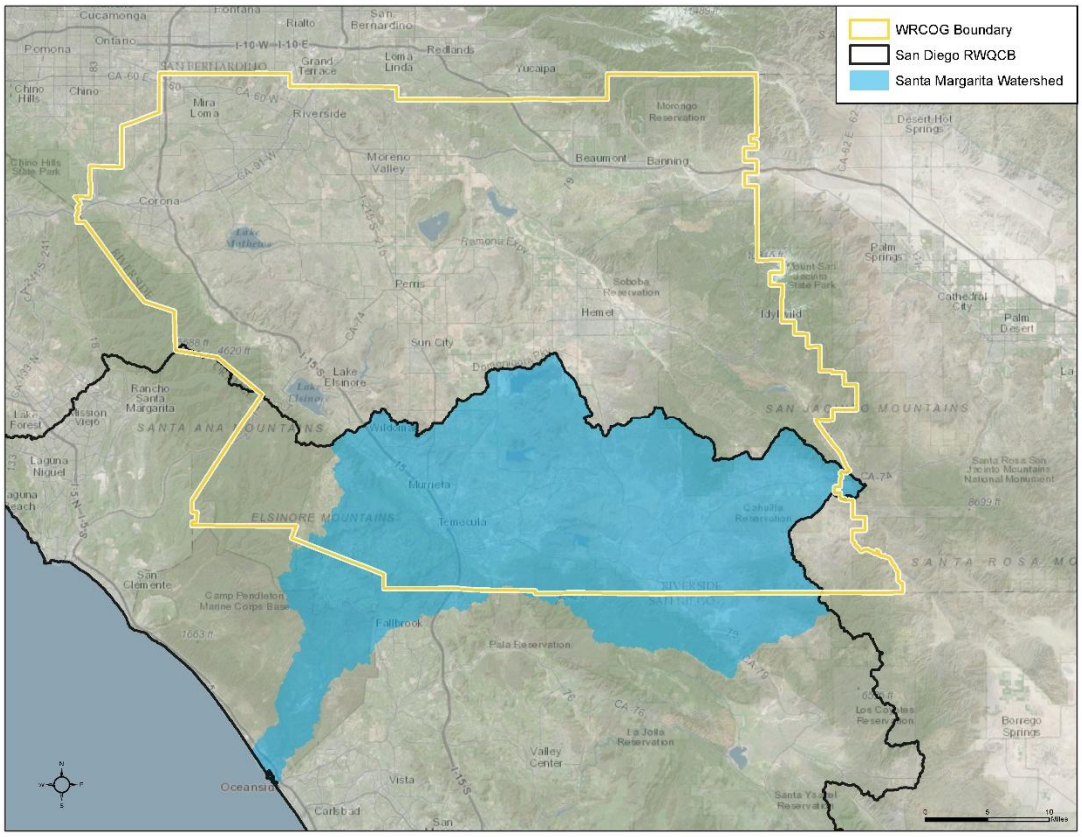

Figure 1. Jurisdictions Associated with the Santa Margarita River Watershed

This report documents the results of two macro scale, regional mapping elements developed by WRCOG. Specifically, WRCOG is evaluating potential changes in runoff and sediment discharge using a geographic information system (GIS)-based watershed-scale analysis of the upper Santa Margarita River watershed (SMR). This report includes a description of the

[1] http://www.wrcog.cog.ca.us/DocumentCenter/View/151

GIS data inputs that were utilized to determine the hydrologic response unit (HRU), the dominant hydrologic process and the potential coarse sediment yield for the SMR.

1.1 BACKGROUND

This report is being developed in response to the National Pollutant Discharge Elimination System (NPDES) Permit and Waste Discharge Requirements for Discharges from the Municipal Separate Storm Sewer Systems (MS4s) Draining the Watersheds within the San Diego Region, (MS4 Permit), which was adopted on May 8, 2013, became effective on June 27, 2013 and was amended by Order No. R9-2015-0001 and Order No. R9-2015-0100. The MS4 Permit requires a Water Quality Improvement Plan (WQIP) for each of the Watershed Management Areas under the jurisdiction of the San Diego RWQCB. The purpose of the WQIP is to further the Clean Water Act's objective to protect, preserve, enhance, and restore the water quality and designated beneficial uses of waters of the state (San Diego RWQCB 2015). A WQIP is required for each Watershed Management Area and therefore requires a Watershed Management Area Analysis (WMAA). A WMAA is a watershed-scale analysis that identifies important characteristics, such as hydrologic processes, sediment yield and stream descriptions. The WMAA is specific to the Santa Margarita Region which includes the County of Riverside, the RCFCWCD, the City of Wildomar, City of Murrieta and the City of Temecula (Copermittees). By working together and sharing resources for development of the SMR WMAA, RCFCWCD is evaluating and summarize existing streams; flood control structures; and current and anticipated land use in the SMR. As part of their contribution to the SMR WMAA, WRCOG is evaluating dominant hydrologic processes and potential coarse sediment yield. The final output of the analyses includes GIS layers to identify candidate projects as alternative compliance options. The SMR WMAA will also provide information to support exemptions from the on-site hydromodification management requirements (RCFCWCD, 2017).

The GIS analysis described herein includes two subtasks which will support development of the SMR WMAA. The SMR WMAA elements described herein leverage and build upon work and mapping already conducted, including but not limited to Technical Report 605 (Booth et al. 2010), the 2014 Santa Margarita Hydromodification Management Plan (HMP)[2] and the 2015 San Diego County Regional WMAA (SD WMAA)[3]. The SD WMAA already includes a preliminary analysis of the lower Santa Margarita River. Therefore, given that the analysis of the upper SMR will be integrated with the analysis of the lower SMR, to maintain a consistent, standardized approach among the lower and upper SMR analyses, the methodology described in in this report is the same methodology developed for the SD WMAA (Geosyntec Consultants and Rick Engineering Company, 2015).

2 HYDROLOGIC RESPONSE UNIT

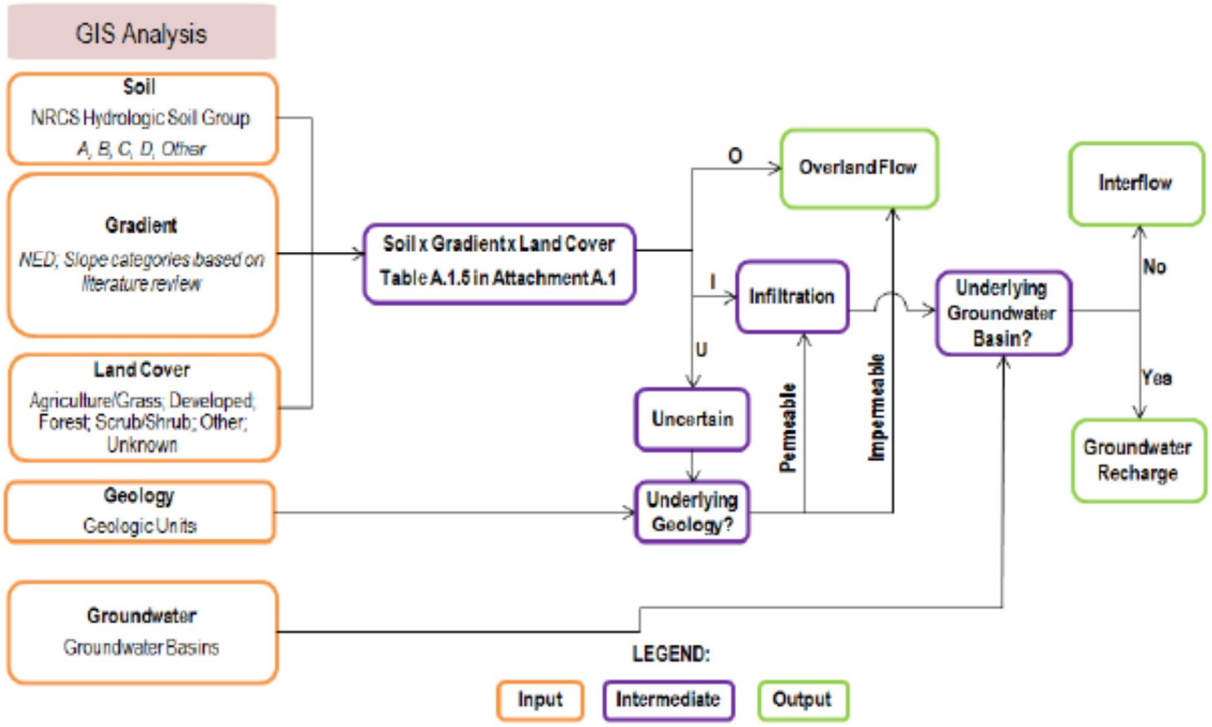

Figure 2. Hydrologic Response Unit and Hydrologic Process Flow Chart

2.1 HYDROLOGIC RESPONSE UNIT END POINTS

The MS4 Permit requires that the WMAA analysis includes a description of dominant hydrologic processes, such as areas where groundwater recharge, interflow or overland flow likely dominate (San Diego RWQCB, 2015). An evaluation of dominant hydrologic processes in the SMR watershed, however, should also consider evapotranspiration (ET). ET is the quantity of water transpired by plants, retained in plant tissues, and evaporated from plant tissues and surrounding soil surfaces (Department of Water Resources, 2005). A comparison of the estimated mean annual precipitation, (4 – 10 inches), over a thirty-year timespan in the Riverside-area watersheds with the estimated fraction of precipitation lost to evapotranspiration (90 – 99 percent) in the same area and over the same time frame, suggests that ET is the dominant hydrologic process in Riverside-area watersheds (Sanford and Selnick, 2013). Therefore, theoretically, if all the annual precipitation for the Riverside-area watersheds remained stationary where it fell and did not either infiltrate or runoff to downstream receiving waterbodies, then the precipitation would be loss to ET. Rain events, however, often produce runoff in these watersheds, especially in the urbanized areas, where the topography and land cover tend to accelerate the runoff rate downstream rather than allowing the runoff to be stored or collected and thus maximizing ET.

This analysis, however, is focused on developing information and mapping to gain an understanding of the macro-scale opportunities for locating projects that take advantage of either capturing overland flow for treatment or for supplementing the groundwater regime (Figure 2). Therefore, after considering the effects of ET and an intermediate category of infiltration,

the predicted fate of runoff within the SMR was evaluated based on the hydrologic process endpoints - overland flow, interflow[4], or groundwater recharge.

The hydrologic response endpoint (i.e., overland flow, infiltration, interflow or groundwater recharge) was derived by first integrating soil, gradient and land cover datasets into hydrologic response units (HRUs). The HRUs were then incorporated as a layer onto a basemap and the data were grouped into several discrete categories and ultimately classified across the SMR. This process is summarized as Figure 2 (Geosyntec Consultants and Rick Engineering Company, 2015).

2.2 DATA TYPES AND ACQUISITION

GIS data were acquired from public-domain sources as indicated below.

- United States Department of Agriculture/National Resources Conservation Service (USDA/NRCS) Web Soil Survey: https://websoilsurvey.sc.egov.usda.gov/App/HomePage.htm and USDA/NRCS Digital General Soil Map of the United States: https://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/survey/geo/?cid=nrcs142p2_053629
- USGS National Elevation Data Set (NED) 1/3 arc-second DEM: https://catalog.data.gov/dataset/usgs-national-elevation-dataset-ned
- https://viewer.nationalmap.gov/basic/
- Land Cover/Vegetation: https://gis.countyofriverside.us/arcgis_public/rest/services/OpenData/NaturalFeaturesAndHazards/MapServer/4
- Soils - National Resource Conservation Service: http://www.ncgc.nrcs.usda.gov/products/datasets/ssurgo/
- Geologic Units: http://www.conservation.ca.gov/cgs/information/geologic_mapping
- Groundwater: Metropolitan Water District of Southern California. 2007. Groundwater assessment study

2.2.1 UPPER SANTA MARGARITA RIVER WATERSHED

The San Diego Association of Governments (SANDAG) Hydrologic Basins Layer was utilized to delineate the SMR. A vector dataset (shapefile) with basin and sub-basin delineations organized by the 8-digit hydrologic unit code from the USGS Hydrologic Unit Maps was available from CalWater. After the SMR was extracted, an examination of its boundaries was compared against a 10-m DEM hillshade. In cases where the boundary seemed inadequate, the DEM was used to improve the watershed delineation with ArcInfo Hydrology routines. After the area of analysis was sufficiently well-defined, the analysis layers were 'clipped' to its boundaries and re-projected to a common coordinate system.

2.2.2 HYDROLOGIC SOIL GROUPS

Soil categories were based on NRCS Hydrologic Soil Group (HSG) classifications, which are commonly used to describe runoff/infiltration potential of soils on a regional scale. There are four HSGs: A, B, C, and D and three dual groups: A/D, B/D and C/D. HSGs are based on the rate of water infiltration, with Group A having the highest rates and Group D having the lowest rates. In the dual groups, the first letter is for drained areas and the second letter is for undrained areas. The following describes the methodology used to assign a single HSG rating for each of the dual groups identified.

Over two hundred polygons, equating to an area of approximately 7,000 acres in the SMR watershed GIS were rated with a dual HSG. Dual HSG ratings were evaluated based on the mapped geologic unit as determined by published geologic mapping information, a desktop evaluation and soils laboratory results. Specifically, the mapped geologic units were compiled into similar categories and then referenced with a geologic unit name. Geologic units were then categorized as either "coarse" or "fine" based on typical weathering characteristics for the bedrock unit or primary grain size of the

[4] Interflow takes place following storm events as shallow subsurface flow (usually within 3 to 6 feet of the surface) occurring in a more permeable soil layer above a less permeable substrate (Geosyntec Consultants and Rick Engineering Company 2015).

sedimentary unit. For example, some geologic units weather to a coarse material such as silty sand and were therefore classified as “coarse”. Geologic units that weather to a sandy clay were classified as “fine”. Regarding sedimentary formations that are usually associated with variable amounts of coarse and fine units, the final classification was based on the predominating composition, i.e., sandstone/silty sand versus claystone. Finally, given that silty sands drain very quickly, any geologic unit identified as coarse was considered drained and was identified as either HSG A, B, or C. Whereas, geologic units classified as “fine” were considered undrained and were rated as HSG D in the GIS database.

For HRUs considered uncertain (U), the underlying regional geology was used to evaluate whether overland flow or infiltration were dominant, consistent with the San Diego County WMAA analysis (Geosyntec Consultants and Rick Engineering Company, 2015). For HRUs considered uncertain (U), the underlying regional geology (Department of Conservation 2015) was used to evaluate whether overland flow or infiltration were dominant. If the underlying geology was considered impermeable, then these uncertain areas were considered to have overland flow as its dominant hydrologic process. If the underlying geology was considered permeable, then these uncertain areas were dominated by infiltration. The determination of whether a geologic unit is impermeable or permeable was based on desktop evaluation and the best professional judgment of a Geotechnical Engineer. This analysis was performed in GIS.

2.2.3 SLOPE CLASSES

The hillslope digital elevation model (DEM) was analyzed to produce a grid of slope values, which were subsequently classified into discrete categories. Based on the SD WMAA, the following percentage categories were used to group hillslope gradients: 0 - 2 percent; 2 - 6 percent; 6 - 10 percent; and greater than 10 percent. According to Technical Report 605 (Booth et al. 2010), the 10 percent slope threshold was used because it was determined that slopes steeper than 10 percent are assumed to be dominated by overland flow.

2.2.4 LAND COVER

Land cover categories were defined using the ecology vegetation GIS map layers developed for Western Riverside County in the Santa Margarita region. The vegetation categories in the GIS layer were grouped to match the following land cover categories used in SD WMAA: Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other and Other (Water) (see Table A.1, Appendix A). Land cover categories for Agriculture/Grass, Forest, Scrub/Shrub, Unknown Other and Other (Water) were then related to land use categories using Table A.2 in Appendix A. A land use category for the Developed land cover category was not determined because this land cover was assumed to have overland flow as its dominant hydrologic process. Table A.3 in Appendix A displays the results showing how the land cover categories related to land use.

HYDROLOGY CHARACTERISTICS BASED ON LAND COVER

For each of the land cover/land use categories the ratio of precipitation lost to evapotranspiration (i.e. an evapotranspiration coefficient) was estimated using the process described below as provided in the SD WMAA (Geosyntec Consultants and Rick Engineering Company, 2015). Since precipitation is considered as the sum of the resulting runoff, infiltration, and evapotranspiration, the coefficients for these three hydrologic pathways sum to one using Equation (Eq) 1.

Runoff Coefficient + Infiltration Coefficient + Evapotranspiration Coefficient = 1 (Eq. 1)

EVAPOTRANSPIRATION ESTIMATE

To estimate the evapotranspiration (ET) coefficient for each land cover, the runoff coefficient was identified by evaluating the highest runoff potential for the most common storm conditions. Using this, the ET coefficient was calculated as the difference (i.e., ET Coefficient = 1 –Runoff Coefficient). The ET coefficient calculated for the highest runoff potential was then applied to all soil types and slopes within each land use category.

INFILTRATION ESTIMATE

The infiltration coefficient for each applicable HRU (i.e., combination of soil, gradient, and land cover) was estimated by subtracting both the runoff coefficient, and the ET coefficient, from one (i.e., Infiltration Coefficient = 1 – Runoff Coefficient – ET Coefficient).

RUNOFF ESTIMATE

For each applicable HRU, the runoff coefficient was divided by the infiltration coefficient to obtain a ratio representing the potential for runoff or infiltration. The higher the ratio, the greater the potential for runoff to be a more dominant hydrologic process than infiltration. Similarly, the lower the ratio, the greater the potential for infiltration to be a more dominant hydrologic process than runoff.

ASSOCIATE RUNOFF AND INFILTRATION HRUS

The following designations were assigned to each applicable HRU based on the runoff to infiltration ratio (i.e., runoff coefficient/infiltration coefficient). These designations were based on best engineering judgment with the underlying assumption that if a runoff or infiltration coefficient is more than 50 percent greater than its counterpart, then the prevailing process is considered dominant.

- HRUs with runoff to infiltration ratios greater than 1.5 (3:2 ratio) were assumed to have relatively high runoff and overland flow was considered its dominant hydrologic process. These HRUs are designated by the letter “O” (Overland flow is dominant process). Table A.4 in Appendix A summarizes these findings in tabular format.
- HRUs with runoff to infiltration ratios less than 0.67 (2:3 ratio) were assumed to have relatively high infiltration and its dominant hydrologic process was either interflow or groundwater recharge, based on analysis described in subsequent steps. These HRUs are designated by the letter “I” (Interflow is dominant process) in Table A.4, Appendix A.
- For HRUs with runoff to infiltration ratios ranging from 0.67 to 1.5, it was uncertain whether it was dominated by overland flow or infiltration. These HRUs are designated by the letter “U” (Dominant process is uncertain) in Table A.4, Appendix A.
- For HRUs that have a Developed land cover or a gradient greater than 10 percent, the runoff to infiltration ratios were not calculated because these HRUs were assumed to have overland flow as the dominant hydrologic process. These HRUs are designated by the letter “O” (Overland flow is dominant process) and are summarized in Table A.5, Appendix A.

2.2.5 GEOLOGIC UNIT

The geology layer was categorized based on rock types, the predominant sediment size generated upon erosion, and their associated erodibility (Booth, et al., 2010). The attribution (and thus the naming) of the geology classes included the following categories:

- Coarse Bedrock (CB),
- Coarse Sedimentary Impermeable (CSI),
- Coarse Sedimentary Permeable (CSP),
- Fine Bedrock (FB),
- Fine Sedimentary Impermeable (FSI),
- Fine Sedimentary Permeable (FSP), and
- Other (O).

The underlying geology was then evaluated to determine if it was permeable or impermeable. This determination was based on a desktop evaluation using the best professional judgment of a Certified Engineering Geologist. All geologic units identified as permeable were considered to have infiltration as the hydrologic endpoint. All impermeable layers were considered to have overland flow as the hydrologic endpoint. The Certified Engineering Geologist also performed a desktop evaluation of any HRUs that were identified as uncertain. Again, if the underlying geology was considered permeable, then

these uncertain areas were considered to be dominated by infiltration. Likewise, if the underlying geology was considered impermeable, then these uncertain areas were considered to be dominated by overland flow.

2.2.6 GROUNDWATER BASINS

For HRUs with relatively high infiltration the presence or absence of a regional groundwater basin underlying these areas determined whether the dominant hydrologic process was designated as interflow or groundwater recharge. The groundwater recharge hydrologic process was assigned as dominant for those applicable areas which have an underlying groundwater basin. The interflow hydrologic process was assigned as dominant for those applicable areas which did not have an underlying groundwater basin.

2.2.7 DOMINANT HYDROLOGIC PROCESS RESULTS

The resulting GIS map displaying the spatial distribution of dominant hydrologic processes (i.e., overland flow, interflow and groundwater recharge) within the SMR is provided in Appendix B. Based on this analysis, overland flow, is the predominant hydrologic process in the SMR, which was verified by the Copermittees as part of their review process.

3 CRITICAL COARSE SEDIMENT YIELD ANALYSIS

The Critical Coarse Sediment Yield analysis predicts the potential critical coarse sediment yield areas and is based on the Geomorphic Landscape Unit (GLU) methodology presented in Technical Report 605 (Booth et al. 2010) and the SD WMAA (Geosyntec Consultants and Rick Engineering Company, 2015). The GLU methodology characterizes the magnitude of sediment production from areas using three factors judged to exert the greatest influence on the variability of sediment-production rates: geology types, hillslope gradient, and land cover. The GLU layer was derived by overlaying hillslope, land cover, and geology, and then assigning a relative sediment-production rate (i.e., Low, Medium, and High) to each of the resulting categories. The GLU approach provided a useful, rapid framework to identify sediment-delivery attributes of the SMR. The process to integrate these factors into GLUs is indicated as a flow chart in Figure 3 (Geosyntec Consultants and Rick Engineering Company 2015).

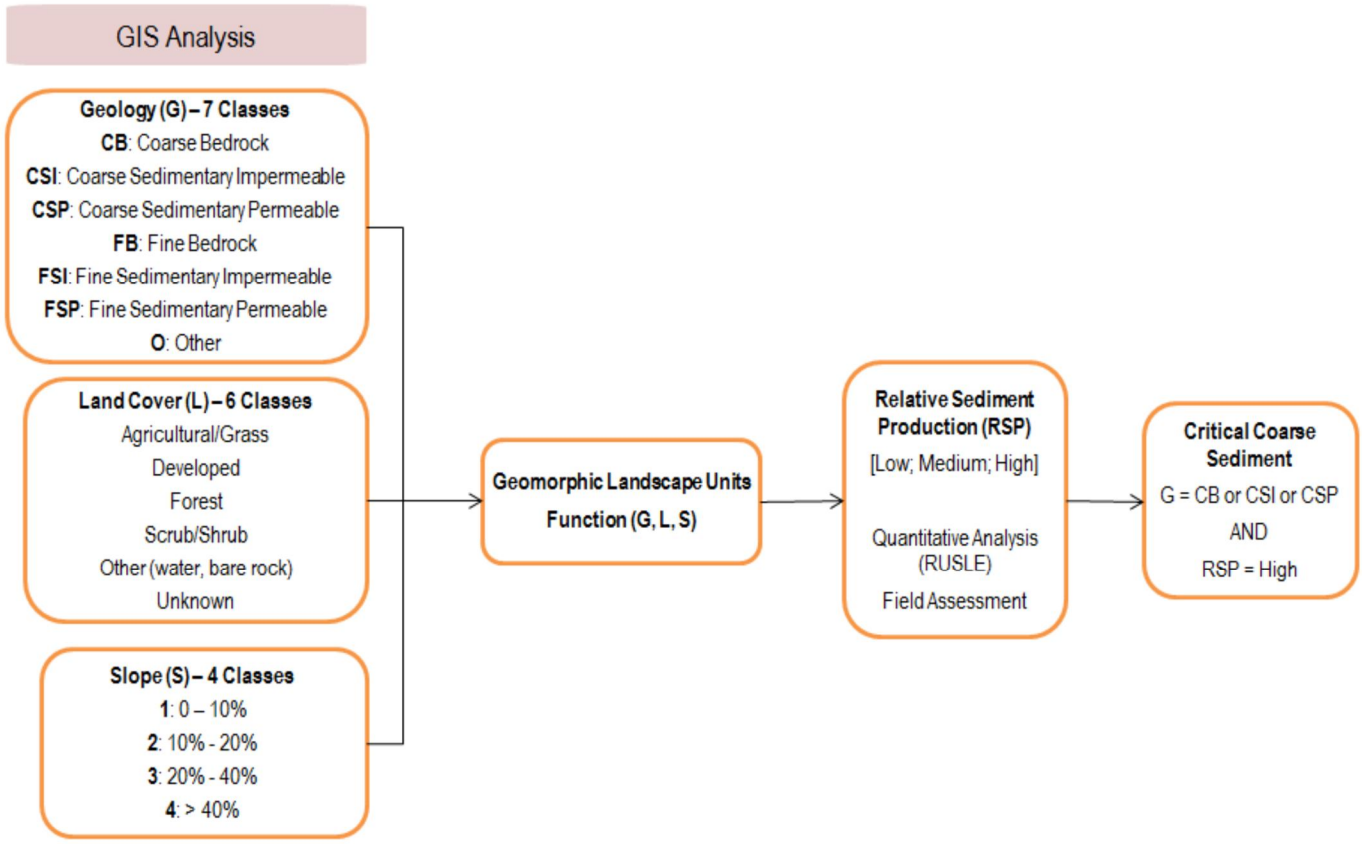

Figure 3. Potential Critical Coarse Sediment Yield Analysis

3.1 DATA TYPES AND ACQUISITION

GIS data were acquired from public-domain sources as indicated below.

- Geologic Units: http://www.conservation.ca.gov/cgs/information/geologic_mapping
- Land Cover/Vegetation: https://gis.countyofriverside.us/arcgis_public/rest/services/OpenData/NaturalFeaturesAndHazards/MapServer/4

- USGS National Elevation Data Set (NED) 1/3 arc-second DEM: https://catalog.data.gov/dataset/usgs-national-elevation-dataset-ned
- https://viewer.nationalmap.gov/basic/

3.1.1 GEOLOGIC UNITS

The geology layer was categorized based on rock types, the predominant sediment size generated upon erosion, and their associated erodibility. The attribution (and thus the naming) of the geology classes included the following categories:

- Coarse Bedrock (CB),
- Coarse Sedimentary Impermeable (CSI),
- Coarse Sedimentary Permeable (CSP),
- Fine Bedrock (FB),
- Fine Sedimentary Impermeable (FSI),
- Fine Sedimentary Permeable (FSP), and
- Other (O).

Of the 34 Geologic Units, 20 required a desktop evaluation by a Geotechnical Engineer to determine if the geologic units would weather to a coarse material such as silty sand or to a fine sandy clay. The desktop evaluation yielded results for all of the geologic units except two, Qsu and Qw. Given that these two units represented approximately 4 percent of the data, a site visit, including soil sample collection, was conducted to verify the grain size of the weathered material.

At the Qw site, the soils were classified as a yellowish brown Silty Sand with little (7 percent) gravels. The grain size of the sand varied between fine to coarse. It was determined that the sediment production from this geologic unit is considered medium to high due to its coarseness and looseness. In addition, this material is considered permeable with a hydrologic soil group rating of A.

At the Qsu site, the soils were classified as a yellowish brown Silty Sand with trace (2 percent) gravels. It was determined that the sediment production from this geologic unit is considered medium to high due to its coarseness and looseness. In addition, this material is considered permeable with a hydrologic soil group rating of A. The field and laboratory report documenting the confirmed results are provided in Appendix C. Table D.1 in Appendix D summarizes how each of the map units related to a geologic grouping.

3.1.2 LAND COVER

Land cover categories were defined using the ecology vegetation GIS map layers developed for Western Riverside County in the Santa Margarita region. The vegetation categories in the GIS layer were grouped to match the following categories used in the SD WMAA: Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other (Water), and Unknown.

3.1.3 SLOPE CLASSES

The hillslope DEM was analyzed to produce a grid of slope values, which were subsequently classified into discrete categories. Based on the SD WMAA, the following category percentages were used to categorize hillslope gradients: 0 to 10 percent; 10 to 20 percent; 20 to 40 percent; and greater than 40 percent.

GLU RESULTS

The result of evaluating geology, land cover and slope equated to approximately 130 GLUs within SMR. These GLUs were then evaluated to determine their relative sediment production.

3.1.4 GEOLOGIC GROUPS

Per the SD WMAA, the geologic groups considered to have the potential to generate coarse sediment are: Coarse Bedrock (CB); Coarse Sedimentary Impermeable (CSI); and Coarse Sedimentary Permeable (CSP). An exhibit showing the regional geologic groupings is presented in Appendix E.

3.1.5 GLU AND SEDIMENT PRODUCTION

Relative sediment production was estimated for each GLU using the Revised Universal Soil Loss Equation (RUSLE) (see Eq. 2).

A = R x K x LS x C x P (Eq. 2), where

A = estimated average soil loss in tons/acre/year
R = rainfall-runoff erosivity factor
K = soil erodibility factor
LS = slope length and steepness factor
C = cover-management factor
P = support practice factor; assumed 1 for this analysis

Datasets used to estimate the average soil loss were acquired from public-domain sources as indicated below.

- RUSLE R Factor: ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_R_Factor/5
- RUSLE K Factor: State Water Resources Control Board: ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_K_Factor/
- RUSLE LS Factor: State Water Resources Control Board: ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_LS_Factor/
- RUSLE C Factor: US EPA, EMAP West Metric Browser: https://archive.epa.gov/esd/archive-nerl-esd1/web/html/wemap_download.html

GIS analysis was used to calculate the area weighted estimate of R, K, LS and C factors using the datasets listed above. For the developed land[6] cover the C factor was adjusted to 0 for the regional estimate to account for management actions implemented on developed sites (e.g., impervious surfaces). The estimated average annual soil loss ranged from 0 to 23 tons/acre/year.

To assess the amount of relative risk to stream channels resulting from watershed-scale changes in sediment yield and/or water delivery, the following opinions included in Technical Report 605 (Booth et al. 2010) were considered:

> *"The challenge in implementing this step is that presently we have insufficient basis to defensibly identify either low-risk or high-risk conditions using these metrics. For example, channels that are close to a threshold for geomorphic change may display significant morphological changes under nothing more than natural year-to-year variability in flow or sediment load.*
>
> *Acknowledging this caveat, we nonetheless anticipate that changes of less than 10 percent in either driver are unlikely to instigate, on their own, significant channel changes. This value is a conservative estimate of the year-to-year variability in either discharge or sediment flux that can be accommodated by a channel system in a state of dynamic equilibrium. It does not "guarantee," however, that channel change may not occur—either in response to yet modest alterations in water or sediment delivery, or because of other urbanization impacts (e.g., point discharge of runoff or the trapping of the upstream sediment flux; see Booth 1990) that are not represented with this analysis.*
>
> *In contrast, recognizing a condition of undisputed "high risk" must await broader collection of regionally relevant data. We note that >60 percent reductions in predicted sediment production have resulted in both minimal*

[5] R-Factor database provided by Geosyntec, January 2017.
[6] Developed (i.e., impervious) area data layer provided by WRCOG, January 2017.

(McGonigle) and dramatic (Agua Hedionda) channel changes, indicating that "more data" may never provide absolute guidance. At present, we suggest using predicted watershed changes of 50 percent or more in either runoff (as indexed by change in impervious area) or sediment production as provisional criteria for requiring a more detailed evaluation of both the drivers and the resisting factors for channel change, regardless of other screening-level assessments. Clearly, however, only more experience with the application of such "thresholds," and the actual channel conditions that accompany them, will provide a defensible basis for setting numeric standards."

Considering the thresholds indicated above, the relative sediment production rating for each GLU followed the criterion indicated below:

- Low: Soil Loss < 3.4 tons/acre/year (GLUs that have a soil loss of 0 to 3.39 tons/acre/year produce approximately 10 percent of the total potential coarse sediment soil loss from the SMR)
- Medium: 3.4 tons/acre/year < Soil Loss <9.6 tons/acre/year (GLUs that have a soil loss ranging from 3.40 to 9.55 tons/acre/year produce approximately 50 percent of the total potential coarse sediment soil loss from the SMR)
- High: >9.6 tons/acre/year (GLUs that have a soil loss greater than 9.57 tons/acre/year produce approximately 40 percent of the total potential coarse sediment soil loss from the SMR)

Results from the quantitative analysis along with GLUs that were rated as critical coarse sediment yield areas are summarized in tabular format in Appendix E.

The resulting GIS map showing the spatial distribution of the potential critical coarse sediment yield areas within the SMR is provided in Appendix G. Based on this analysis it was estimated that 28 percent of the of the SMR study area is a potential coarse sediment yield area and 9 percent of the SMR study area is a potential critical coarse sediment yield area. The majority of the potential critical coarse sediment yield areas were identified to be in the Scrub/Shrub land cover areas with hillslope gradients ranging from 20 to 40 percent.

As a result of the regional-scale datasets, and commensurate data resolution, used to map the potential critical coarse sediment yield areas, some areas may have been mapped that in reality do not produce critical coarse sediment as they are existing developed areas. As such, an opportunity for Copermittees to incorporate more refined data into the preliminary SMR WMAA GIS dataset based on local knowledge and review of current aerial images was provided. The City of Temecula, the City of Wildomar, the City of Murrietta, and RCFCWCD evaluated the data for their respective jurisdictional areas during the review process.

4 SITE ASSESSMENT

After developing the GIS that related the GLUs to a relative sediment production, WSP conducted a series of site visits within the SMR to compare GIS-based predictions with field-based observations. Forty-three sites were selected (see Figure F.1, Appendix F) for the assessment based on their accessibility and their distribution according to the following criteria:

- Geologic grouping
- Land cover
- Slope category

The following section includes a discussion of the protocol utilized for the site assessment and is based on the field assessment strategy described in the SD WMAA (Geosyntec Consultants and Rick Engineering Company, 2015).

4.1 PRE-FIELD ACTIVITIES

Prior to conducting field activities, the consultant team reviewed available published geologic information at each site location and prepared satellite imagery of each site using Google Earth. Pre-field activities consisted of evaluating site access at each location using aerial imagery and logistics were coordinated based on regional site locations to maximize field efficiency.

4.2 SITE RECONNAISSANCE

The WSP geology team performed site reconnaissance at forty-three locations on 9 and 10 May 2017. The reconnaissance consisted of:

- Visual soil classification,
- Assessing existing vegetative cover (0-100 percent),
- Qualitative assignment of existing sediment production (low, medium, and high) [based on existing vegetative cover],
- Qualitative assignment of potential sediment production (low, medium, and high) [assuming there is 0 percent vegetative cover], and
- Identifying existing erosional features.

Descriptions and visual classifications of the surficial materials were based on the Unified Soil Classification System (USCS). Underlying geologic units were confirmed where exposed formations were observed within the individual site limits.

4.3 SITE AND GEOLOGIC CONDITIONS

Site condition knowledge was developed from a review of available geologic literature, previous geologic and geotechnical investigations by the WSP team in the study region, professional experience and site reconnaissance.

4.3.1 SURFACE CONDITIONS

Site locations were selected in areas with open space with the exception of sites 1, 21, 22, 30 and 31 which were situated within developed areas with paved streets and sidewalks. The surface conditions at the site locations were typically characterized by relatively flat terrain (< 5 percent) with a few instances where slope gradients ranged from 10 to 40 percent. At the time of the site visit the natural hillsides along the areas of interest were covered by varying degrees of moderate to dense growth scrub brush, low grasses, and scattered trees. The only observed erosional feature included potential erosional gullies at Site 64 within the access road to the site where no ground cover existed. No geomorphic features were observed

and the only sources of ground disturbance were noted as active construction at Sites 54 and 55 and active construction 100-200 feet south and east of Site 59. An evaluation of the existing and potential sediment production for each site was determined based on surface conditions. Sediment production was assigned as “high, medium, or low” based on the existing conditions and the geology team’s professional experience.

4.3.2 SURFICIAL DEPOSITS

Surficial deposits observed included alluvium, colluvium, and debris (e.g., silt, sand, silty sand and fine gravel). The composition and grain size of these materials were variable (fine to medium grained; fine to coarse grained) depending on the age, parent sources, and mode of deposition. Granite boulders were also observed in portions of the study area.

4.3.3 GEOLOGIC CONDITIONS

Knowledge of the subsurface conditions at the site locations was based on a review of available published geologic information, professional experience, site reconnaissance, previous explorations and geotechnical investigations performed by the team in the study region.

4.4 RESULTS

The results of the site assessment along with photographic documentation are provided in Appendix F. Overall, there were 133 GLU’s associated with the SMR and the field team was tasked with evaluating GLUs at 43 sites. The 43 sites represented 25 unique GLUs which equated to verifying approximately 20 percent of the entire GLU dataset. Of the 129 GIS-based predictions (e.g., 43 GLUs with 3 characteristics per GLU), 116 GIS-based predictions (or 90 percent) matched the field-based observations for land cover, geologic grouping and slope category. Of the 13 GIS-based predictions that resulted in mismatches, 2 of the sites (Sites 54 and 55) were within active construction areas, making verification of the GLU impossible. Nine of the mismatches were attributed to the assignment of the geologic grouping. Specifically, 8 sites were classified as a Granitic (gr) geologic unit, whereas in the field, the geologists determined that the geologic units represented Alluvial deposits or fill. There were a few instances, (Sites 49, 53 and 58), where large granitic boulders were adjacent to the site and the field team indicated that this may have been the reason why the site was classified as granitic. For the final mismatch at Site 51, the geologic unit was classified as Granitic and the field team classified the geologic unit as Qvoa or fill. It should be noted that the Qvoa geologic unit weathers as a coarse grain which is similar to the granitic geologic unit that also weathers to a coarse grain (see Table D.1 in Appendix D). In general, these mismatches may be attributed to a function of the public domain data used which does not reflect changes to particular areas that have occurred since the underlying data was developed. The relatively high agreement (90 percent) between the GIS-based predictions and the field-based observations may be attributed to scrutinizing the land cover data by comparing some of the land cover areas with aerial images and having to concentrate the locations to ensure ease of access. Therefore, the GLU assignments were considered valid for estimating relative sediment production.

5 POTENTIAL SEDIMENT SOURCE AREA

5.1 SAN DIEGO RWQCB COMMENTS

A comparison between the potential critical coarse sediment yield areas within the Upper SMR and within the San Diego County portion of the Santa Margarita watershed management area was conducted as a response to San Diego Regional Water Quality Control Board (San Diego RWQCB) comments. Differences in potential critical coarse sediment yield areas along the county line were noted in the eastern portion of the watershed along with a lack of potential critical coarse sediment areas within the northeastern portion of the watershed management area.

To verify these differences, the San Diego RWQCB requested an evaluation of United States Geological Survey mineral resource maps online (USGS 2018). Along the border, it was noted that sand and gravel deposits were absent within a 2-mile radius north and south of the border. Sand and gravel deposits, however, were noted in areas generally downstream of CB, CSI, and CSP geologic units. These deposits were therefore considered as an area that may be a potential sediment source area and it was decided that further evaluation was warranted.

The identification of potential sediment source areas was determined using the following process:

- Overlay sand/gravel deposits onto Geology Grouping GIS layer
- Using USGS quad maps, identify the tributary drainage area for each deposit located in a CB, CSI or CSP area
- Exclude the following areas:
  - Agricultural Land
  - Developed Land
  - Non Permittee Area
    - Camp Pendleton
  - Protected Lands

The resulting GIS map showing the spatial distribution of the potential critical coarse sediment yield areas along with potential sediment source areas within the SMR is provided in Appendix H.

6 CONCLUSIONS

6.1 UPPER SANTA MARGARITA RIVER WMAA

The SMR WMAA will be developed by integrating the mapping results of the HRU and coarse sediment analyses provided in this report with the mapping results of existing streams, future land uses and physical structures developed by RCFCWCD. Under the conditions of the NPDES MS4 Permit, the Copermittees may use the integrated analyses and information provided in the SMR WMAA to support exemptions from the on-site hydromodification BMP requirements. Moreover, the Copermittees may also use the results of the SMR WMAA to identify and compile a list of candidate projects that Priority Development Projects may use as an alternative compliance option. (RCFCWCD 2017). Opportunities being considered as candidate projects are provided in the Santa Margarita Watershed Management Area Analysis dated June 2018.

C EVALUATION OF Qw AND Qsu GEOLOGIC UNITS

Memorandum

Project #: 12853

Date: March 17, 2017

To: Veronica Seyde

From: S. V. (Jag) Jagannath, PhD, PE, GE and Ian Lau, PE

Subject: WSP I PB Site Visit Observation for SMR WMAA

Previously, we had provided geologic / geotechnical desktop study of about 20 Geologic Units within the Santa Margarita River Watershed study area with respect to nature of anticipated grain size of weathered material from these geologic units and to aid the GIS team in determination of Hydrologic Units. Based on that study, you had identified following two Geologic Units that required further evaluation.

- Qw - Wash deposits (late Holocene)-Unconsolidated boulders to sandy alluvium of active and recently active washes
- Qsu - Undifferentiated Surficial Deposits; includes colluvium, slope wash, talus deposits, and other surface deposits of all ages; mostly consolidated

Purpose of this memo is to summarize the findings of the field reconnaissance / observation conducted on March 8, 2017 for these Geologic Units, collection of soil samples and soil classification based on laboratory testing. Site maps showing the sample locations, field notes, photographs during site visit and laboratory test results of representative samples are provided in the attachments.

Field Observation:

On March 8, 2017, WSP I PB engineers conducted field observation to evaluate the above two geologic units (Qw and Qsu). The two locations were determined using aerial imagery, site access and available geologic maps. Two bulk bags of near-surface representative soil samples (one each from these Geologic Units) were collected for initial visual classification in the field and laboratory testing for grain size distribution.

Sample S-1 is selected to evaluate geologic unit Qw. The site is located west of the intersection of De Portola Road and Belle Chaine Loop (approximate latitude / longitude: N33º29'50.3", W117º2'1.5"). General topography of the site is relatively flat and is located within a developed ranch and agricultural farmland area. Minimal existing vegetation (<5%) is observed adjacent to the sampling location, although scattered trees and scrubs can be seen within several privately owned parcels nearby.

Based on the visual and laboratory test result, the soil is classified as yellowish brown Silty Sand with little (7%) gravels. Grain size of sand varies between fine to coarse. It is determined that the sediment production from this geologic unit when without ground cover is considered medium to high due to its grain coarseness and looseness. In addition, this material is considered as permeable with a Hydrologic Unit A.

Sample S-2 is selected to evaluate geologic unit Qsu. The site is generally located in the walking trails, generally southwest of the paved Butterfield Stage Road (dirt path towards Morgan Hill Trail) (approximate latitude / longitude: N33°28'11.5", W117°3'40.9"). The site is near the bottom of foothill and general topography of the site varies from relatively flat to fairly-sloped (20-30%). Majority of the area is currently covered with low lying vegetation (except the dirt covered walkways connecting to the southeasterly trails). A concrete V-ditch separated the trail area from the existing track homes development to the west of the sample location..

Based on the visual and laboratory test result, the soil is classified as yellowish brown Silty Sand (consist of mostly fine to medium sand) with trace (2%) gravels. It is determined that the sediment production from this geologic unit when without ground cover is considered medium to high due to its grain coarseness and looseness. In addition, this material is considered as permeable with a Hydrologic Unit A.

Distribution: n/a

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 1

GLU Classification: FSI-DEVELOPED-1

Photo ID: 1 looking SE; 2 looking SE

GPS (Lat/Long):

33.49632207 -117.3111578

Geologic Unit: QIs

Surficial Material Type: Asphalt covered cul-de-sac bounded with dark brown silty SAND colluvium, covered with cobbles/boulders and shallow vegetation.

Existing Vegetative Cover Estimate (Percent): 20%

Existing Sediment Risk (High, Med, Low): Low to Med

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 2

GLU Classification: FSI-FOREST-3

Photo ID: 1 looking NE; 2 looking SE

GPS (Lat/Long):

33.49680079 -117.3105827

Geologic Unit: gr

Surficial Material Type: Granitic boulders covered with old tree branches and brushes

Existing Vegetative Cover Estimate (Percent): 75-80%

Existing Sediment Risk (High, Med, Low): Med (steepness)

Potential Sediment Risk (High, Med, Low): Low to Med

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 3

GLU Classification: CB-SCRUB/SHRUB-3

Photo ID: 1 looking NE; 2 looking NW

GPS (Lat/Long):

33.49618209 -117.3100543

Geologic Unit: gr

Surficial Material Type: Light yellowish brown colluvium / Qls debris with granite boulders 4 to 5 feet in size. Flat area with little vegetation cover.

Existing Vegetative Cover Estimate (Percent): <10%

Existing Sediment Risk (High, Med, Low): Med

Potential Sediment Risk (High, Med, Low): Med to High

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 4

GLU Classification: FSI-Scrub/Shrub-3

Photo ID: 1 looking NE; 2 looking NW

GPS (Lat/Long):

33.49616612 -117.3104793

Geologic Unit: Qls

Surficial Material Type: Light yellowish brown colluvium / Qls debris with granite boulders 4 to 5 feet in size. Flat area with little vegetation cover.

Existing Vegetative Cover Estimate (Percent): <10%

Existing Sediment Risk (High, Med, Low): Med

Potential Sediment Risk (High, Med, Low): Med to High

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/10/2017

Field Team: Paulina Chilingar & Dario Leekam

Location ID: 18

GLU Classification: CSI-OTHER-1

Photo ID: 1 looking S; 2 looking SW

GPS (Lat/Long):

33.58540235 -117.1255313

Geologic Unit: Qvoa Alluvium, possible shallow granite

Surficial Material Type: large boulders 20 feet south. Large group of trees south west. Brown silty SAND, fine to medium grained, covered by grass.

Existing Vegetative Cover Estimate (Percent): 10 to 15%

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/10/2017

Field Team: Paulina Chilingar & Dario Leekam

Location ID: 19

GLU Classification: CB-OTHER-1

Photo ID: 1 looking SW; 2 looking N

GPS (Lat/Long):

33.58507168 -117.1264493

Geologic Unit: Alluvium

Surficial Material Type: large boulders/granite 200 feet West. Actual site on brown silty SAND, very moist, fine to medium grained, covered by shallow brushes (some dry, some green). Depression 20 feet North, possible creek. Slope 1% South to North

Existing Vegetative Cover Estimate (Percent): 10%. 25% in creek

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes: Large Trees 100 feet NorthWest

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 20

GLU Classification: CSI-OTHER-WATER-1

Photo ID:

GPS (Lat/Long):

33.58430838 -117.122567

Geologic Unit: Qvoa (filled with at least 5 feet of water)

Surficial Material Type: Water filled area with lots of vegetation growth. Banks are well covered with brown vegetation and trees

Existing Vegetative Cover Estimate (Percent): None but with water

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 21

GLU Classification: CSI-DEVELOPED-1

Photo ID: 1 looking SW

GPS (Lat/Long):

33.58307841 -117.1221918

Geologic Unit: Asphalt

Surficial Material Type: Pavement. Parking Lot

Existing Vegetative Cover Estimate (Percent): None

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Location ID: 22

GLU Classification: CB-DEVELOPED-1

Photo ID: 1 looking SW

GPS (Lat/Long):

33.58279133 -117.1203132

Geologic Unit: Qvoa (Asphalt / Parking Lot)

Surficial Material Type: Pavement

Existing Vegetative Cover Estimate (Percent): None

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes:

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/10/2017

Field Team: Paulina Chilingar & Dario Leekam

Location ID: 23

GLU Classification: CB-FOREST-1

Photo ID: 1 looking NE; 2 looking E

GPS (Lat/Long):

33.599266 -117.1418295

Geologic Unit: Alluvium or fill

Surficial Material Type: light brown silty SAND, moist, fine to coarse grained. Lots of brushes, trees and branches. Located in divet/depression

Existing Vegetative Cover Estimate (Percent): 50%

Existing Sediment Risk (High, Med, Low): Med to High

Potential Sediment Risk (High, Med, Low): High

100% Vegetative Cover Sediment Risk (High, Med, Low): Med to High

Notes: Line of trees on a dried up creek

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/10/2017

Field Team: Paulina Chilingar & Dario Leekam

Location ID: 24

GLU Classification: CSP-FOREST-1

Photo ID: 1 looking NW

GPS (Lat/Long):

33.5992614 -117.1420466

Geologic Unit: qyf

Surficial Material Type: light bron silty SAND, fine to medium grained, covered with shallow brushes and tree branches. Boulders in the south west direction. 1-2% slope west to east. 2% slope south to north

Existing Vegetative Cover Estimate (Percent): 20-30%

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low-Med

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes: Line of trees 40 feet East; located in divet/depression

Upper Santa Margarita River Watershed

Photo ID: 1 looking N; 2 looking N (close up view)

GPS (Lat/Long):

33.55416725 -117.0982825

Geologic Unit: Qss

Surficial Material Type: 2 to 3% slopes easterly. Covered by 2 to 3 feet tall grassy brushes. Light brown silty SANDSTONE, med to fine grained, potential erosional gullies visible in access road to site where no ground cover exist.

Existing Vegetative Cover Estimate (Percent): 75 to 80%

Existing Sediment Risk (High, Med, Low): Low to Med

Potential Sediment Risk (High, Med, Low): Med to High

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes: ***Site may not be accessible.***

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 65

GLU Classification: CSP-AGRICULTURAL/GRASS-3

Photo ID: 1 looking N; 2 looking NE

GPS (Lat/Long):

33.55446283 -117.0978426

Geologic Unit: Qss

Surficial Material Type: 3 to 5% westerly slope. Ground covered by 2 to 3 feet tall brushes/grass. Light brown silty SANDSTONE, medium to fine grained.

Existing Vegetative Cover Estimate (Percent): 80%

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low to Med (steepness)

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes: ***Site may not be accessible.***

Upper Santa Margarita River Watershed
Coarse Sediment Yield Analysis

Date: 5/9/2017

Field Team: Jag Jagannath & Dario Leekam

Location ID: 66

GLU Classification: FB-AGRICULTURAL/GRASS-1

Photo ID: 1 looking N; 2 looking SW

GPS (Lat/Long):

33.56286659 -117.0713212

Geologic Unit: pKm (unit questionable)

Surficial Material Type: On either side of sandy GRAVEL access road, the ground is covered with 2 to 3 feet tall grassy brown brushes. Light brown silty SANDSTONE, trace gravel, 3 to 5% ground gradient in N-S direction.

Existing Vegetative Cover Estimate (Percent): 80%

Existing Sediment Risk (High, Med, Low): Low

Potential Sediment Risk (High, Med, Low): Low to Med

100% Vegetative Cover Sediment Risk (High, Med, Low): Low

Notes: Low point of N-S drainage crosses sandy Gravel covered access road.

1. Introduction

1.1. Background

On May 8, 2013 the California Regional Water Quality Control Board, San Diego Region adopted Order No. R9-2013-0001; NPDES No. CAS 0109266, National Pollutant Discharge Elimination System (NPDES) Permit and Waste Discharge Requirements for Discharges from the Municipal Separate Storm Sewer Systems (MS4s) Draining the Watersheds within the San Diego Region (Regional MS4 Permit). The Regional MS4 Permit, which became effective on June 27, 2013, replaces the previous MS4 Permits that covered portions of the Counties of San Diego, Orange, and Riverside within the San Diego Region. There were two main goals for the Regional MS4 Permit:

1. To have more consistent implementation, as well as improve inter-agency communication (particularly in the case of watersheds that cross jurisdictional boundaries), and minimize resources spent on the permit renewal process.
2. To establish requirements that focused on the achievement of water quality improvement goals and outcomes rather than completing specific actions, thereby giving the Copermittees more control over how their water quality programs are implemented.

To achieve the second goal, the Regional MS4 Permit requires that Water Quality Improvement Plans (WQIPs) be developed for each Watershed Management Area (WMA) within the San Diego Region. As part of the development of WQIPs, the Regional MS4 Permit provides Copermittees an option to perform a Watershed Management Area Analysis (WMAA) through which watershed-specific requirements for structural BMP implementation for Priority Development Projects can be developed for each WMA. This report presents the Copermittees' approach and results for the regional elements of the WMAA developed for the San Diego County area.

1.2. Watershed Management Area Analysis (WMAA)

The Regional MS4 Permit, through inclusion of the WMAA, provides an optional pathway for Copermittees to develop an integrated approach for their land development programs by promoting evaluation of multiple strategies for water quality improvement and development of watershed-scale solutions for improving overall water quality in the watershed. The WMAA comprises the following three components as indicated in the Regional MS4 Permit:

1. Perform analysis and develop Geographic Information System (GIS) layers (maps) by gathering information pertaining to the physical characteristics of the WMA (referred to herein as WMA Characterization). This includes, for example, identifying potential areas of coarse sediment supply, present and anticipated future land uses, and locations of physical structures within receiving streams and upland areas that affect the watershed hydrology (such as bridges, culverts, and flood management basins).
2. Using the WMA Characterization results, compile a list of candidate projects that could potentially be used as alternative compliance options for Priority Development Projects. Such projects may include, for example, opportunities for stream or riparian area

rehabilitation, opportunities for retrofitting existing infrastructure to incorporate storm water retention or treatment, or opportunities for regional BMPs, among others. Prior to implementing these candidate projects the Copermittees must demonstrate that implementing such a candidate project would provide greater overall benefit to the watershed than requiring implementation of the onsite structural BMPs. Note, compilation or evaluation of potential projects was not performed as part of this regional effort. Identification and listing of candidate projects will be performed for each WMA through the WQIP process for WMAs that elect to submit the optional WMAA as part of the WQIP.

3. Additionally, using the WMA Characterization maps, identify areas within the watershed management area where it is appropriate to allow for exemptions from hydromodification management requirements that are in addition to those already allowed by the Regional MS4 Permit for Priority Development Projects. The Copermittees shall identify such cases on a watershed basis and include them in the WMAA with supporting rationale to support claims for exemptions.

1.3. Scope of Work for Regional WMAA

In July 2013, the Copermittees elected to fund a regional effort to develop elements of the regional WMAA for the 9 San Diego-area WMAs within the County of San Diego that are currently subject to the Regional MS4 Permit, which include:

- Santa Margarita River (for portion in San Diego County)
- San Luis Rey River
- Carlsbad
- San Dieguito River
- Los Peñasquitos
- Mission Bay & La Jolla Watershed
- San Diego River
- San Diego Bay
- Tijuana River (for portion in San Diego County)

The regional-level information developed through this effort is intended to provide consistency across WMAs and serve as the foundation for developing watershed-specific information for each WMA to be developed through the WQIP process. The regional effort scope of work included:

1. Development of GIS map layers that characterize the WMAs using data previously collected, readily available, and provided by the Copermittees, including:
    a. Description of dominant hydrologic processes, such as areas where infiltration or overland flow likely dominates;
    b. Description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral;

c. Current and anticipated future land uses;

d. Potential coarse sediment yield areas; and

e. Locations of existing flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins.

2. Development of a Microsoft® Excel (Excel) template for use by Copermittees to compile lists of candidate projects for an optional alternative compliance program.
3. Development of additional criteria and analyses to support reinstating the following proposed exemptions that were originally developed in the approved 2011 Final Hydromodification Management Plan but not included in the Regional MS4 Permit unless provided by the Copermittees in the WMAA. In addition, development of the associated Hydromodification Applicability/Exemption Mapping.
    a. Exempt River Reaches including:
        i. San Diego River;
        ii. Otay River;
        iii. San Dieguito River;
        iv. San Luis Rey River; and
        v. Sweetwater River
    b. Stabilized Conveyance Systems Draining to Exempt Water Bodies
    c. Highly Impervious/Highly Urbanized Watersheds and Urban Infill, and
    d. Tidally Influenced Lagoons (where data/study provided)

The scope of work for the regional effort excluded performing analysis within the following areas unless data was readily available, as Copermittees do not have jurisdiction over these areas:

1. State Lands;
2. U.S. Departments of Defense land;
3. U.S. National Forest land;
4. U.S. Department of Interior land and
5. Tribal land

Additional description of excluded areas, for the purposes of the Regional WMAA, is indicated in Section 2.3 Land Uses.

1.4. Project Process

The process for developing the Regional WMAA included close coordination with the Land Development Workgroup (LDW) at key points during the project. The LDW is composed of the 21 San Diego-area Copermittees and serves to develop and implement regional land development plans and programs necessary to support the requirements of the Regional MS4 Permit. The consultant team (Geosyntec Consultants and Rick Engineering Company) presented

preliminary project assumptions and methodologies proposed to be used to develop the Regional WMAA to meet the requirements of the Regional MS4 Permit in December 2013. The consultant team incorporated workgroup feedback from this meeting and subsequently presented the preliminary Regional WMAA project results to the LDW in March 2014, again to receive direction and incorporate input on the preliminary results. Subsequently, the draft report was released to the public in July 2014, by a public workshop that included Consultation Panel members from each of the WMAs on July 29, 2014. This version of the report including all of the input described above is being issued for optional inclusion into the respective WQIP Provision B.3 submittals to the SDRWQCB in December 2014.

1.5. Report Organization

This report is organized as follows:

- Chapter 1 provides the project background and purpose;
- Chapter 2 describes the technical basis for characterizing the WMAs;
- Chapter 3 describes the template that can be used by Copermittees to compile the list of candidate projects;
- Chapter 4 summarizes the analyses performed to support reinstating select exemptions from hydromodification control requirements for PDPs;
- Chapter 5 presents the Regional WMAA conclusions;
- Chapter 6 presents the references used for the Regional WMAA;
- Attachment A presents the exhibits and additional supporting information for watershed management area characterization;
- Attachment B presents the exhibits and additional supporting information for hydromodification management applicability/exemptions;
- Attachment C expands on the structure of the geodatabase that hosts the GIS data developed by the WMAA; and
- Attachment D provides a crosswalk between the Regional MS4 Permit requirements for WMAA and this report.

1.6.Terms of Reference

The work described in this report was conducted by Geosyntec Consultants (Geosyntec) and Rick Engineering Company (RICK) on behalf of the County of San Diego and the regional Copermittees.

2. Watershed Management Area Characterization

Watershed health and function are strongly influenced by hydrological and geomorphological processes occurring in the watershed. Both hydrological response and geomorphological response of the watershed are dependent on a variety of physical characteristics of the watershed. To this end, the Regional MS4 Permit specifies a set of data that is required to adequately characterize overall watershed processes as a foundation to enhancing integration and effectiveness of watershed management and water quality programs. The following GIS map layers were developed to characterize the hydrological and geomorphological processes within the 9 WMAs:

- Dominant Hydrologic Processes: A description of dominant hydrologic processes, such as areas where infiltration or overland flow likely dominates;
- Stream Characterization: A description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral;
- Land Uses: Current and anticipated future land uses;
- Potential Critical Coarse Sediment Yield Areas; and
- Physical Structures: Locations of existing flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins.

These GIS layers can be used to:

- Identify the nature and distribution of key macro-scale watershed processes;
- Identify potential opportunities and constraints for regional and sub-regional storm water management facilities that can play a critical role in meeting water quality, hydromodification, water supply, and/or habitat goals within the watershed;
- Assist with determining the most appropriate management actions for specific portions of the watershed; and
- Suggest where further study is appropriate.

2.1. Dominant Hydrologic Processes

The Regional MS4 Permit identifies in the provisions related to the WMAA that a description of dominant hydrologic processes within the watershed must be developed, with GIS layers (maps) as output. The Permit specifically calls for processes "*such as areas where infiltration or overland flow likely dominates*." These particular aspects of the hydrological mechanics of watersheds are particularly important when attempting to understand the macro-scale opportunities for locating projects that take advantage of either capturing overland flow for treatment or for infiltration.

Investigation of the dominant hydrologic processes in the San Diego-area watersheds indicates that evapotranspiration (ET) is the most dominant hydrologic process for the region based on review of a published study (Sanford and Selnick, 2013). ET is the sum of evaporation and plant transpiration in the hydrologic cycle that transports water from land surfaces to the atmosphere. This is conclusion is supported by comparing the 30-year average annual rainfall for the study area (San Diego County east of the peninsular divide) of between 15 and 18 inches per year (San Diego County, 2005) to the average annual ET rates. According to the California Irrigation Management Information System (CIMIS) Reference Evapotranspiration Map (CIMIS, 1999), the study area (within Zones 4, 6, and 9) experiences annual reference ET of 46.6, 49.7 and 59.9 inches, respectively. Therefore, theoretically, if all of the annual precipitation for the San Diego-area watersheds remained stationary where it fell and did not either infiltrate or runoff to local waterbodies where it would be conveyed downstream ultimately to the ocean, it all would be consumed by ET. As such, the effect of ET on the overall hydrologic processes within the San Diego watersheds is a function of the temporal scale over which it acts. Precipitation events often produce runoff in these watersheds, particularly in the urbanized portions, based on the topography and land cover that tend to accelerate the conveyance of runoff downstream rather than collecting, storing, or spreading out that then would maximize the effect of ET.

Because this study is focused on developing information and mapping for the portion of the hydrologic process that informs watershed management decisions, i.e., locating beneficial projects in areas of greatest opportunity, the next tier of dominant hydrologic processes are studied and mapped by this project. As such, the study area was characterized, based on the methodology described in the following section, according to the predicted fate of runoff within the watersheds being either overland flow or infiltration after considering the effects of ET (as well as an intermediate category of interflow). Areas that were mapped as overland flow do not necessarily preclude infiltration but rather indicate the dominant expected process that runoff would experience if not intercepted for the express purpose of infiltrating storm water runoff. The Model BMP Design Manual will provide more detailed guidance and procedures for determining the potential for infiltrating captured storm water at the project level irrespective of the mapping produced in the WMAA. To reiterate, the WMAA mapping is to provide macro-scale processes for high-level analysis and to inform decisions affecting regional scales. Furthermore, the Model BMP Design Manual will indicate the degree to which site-scale BMPs can expect to benefit from ET or how ET is considered in the sizing of BMPs. In brief, typical storm water BMPs only store water for a few days and therefore are not really capable of significant volume disposal through ET. However, pervious area dispersion (i.e., directing storm water runoff to flat areas for spreading and infiltration) has appreciable benefits with regard to ET and is a practice promoted in the BMP Design Manual.

The processes of interest are further defined as follows:

Overland flow: This process can be thought of as the inverse of infiltration; precipitation reaching the ground surface that does not immediately soak in must run over the land surface (thus, "overland" flow). It reflects the relative rates of rainfall intensity and the soil's infiltration capacity: wherever and whenever the rainfall intensity exceeds the soil's infiltration capacity, some overland flow will occur. Most uncompacted, vegetated soils have infiltration capacities of one to several inches per hour at the ground surface, which exceeds the rainfall intensity of even unusually intense storms. In contrast, pavement and hard surfaces reduce the effective infiltration capacity of the ground surface to zero, ensuring overland flow regardless of the meteorological attributes of a storm, together with a much faster rate of runoff relative to vegetated surfaces.

Infiltration and groundwater recharge: These closely linked hydrologic processes are most apparent near ephemeral and perennial conveyances in the San Diego region. Their widespread occurrence is expressed by the common absence of surface-water channels on even steep (undisturbed) hillslopes. Thus, on virtually any geologic material on all but the steepest slopes (or bare rock), infiltration of rainfall into the soil is inferred to be widespread, if not ubiquitous. With urbanization, changes to the process of infiltration are also quite simple to characterize: some (typically large) fraction of that once infiltrating water is now converted to overland flow.

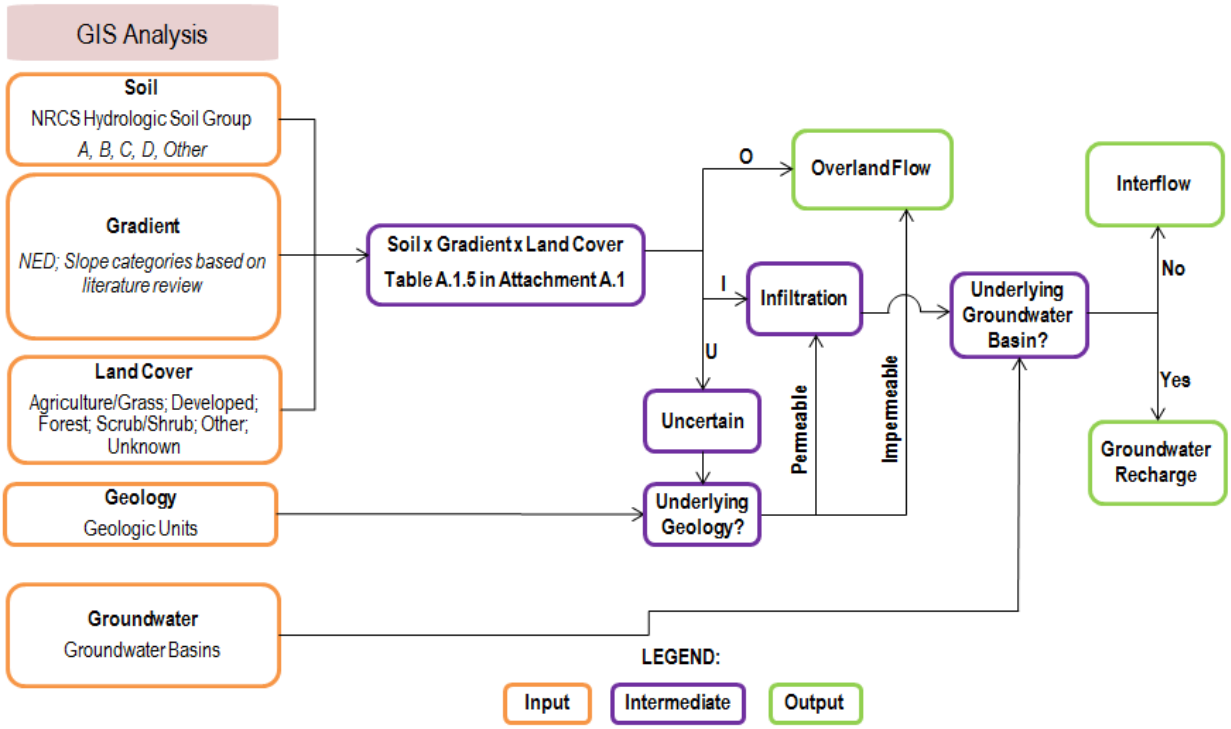
Interflow: Interflow takes place following storm events as shallow subsurface flow (usually within 3 to 6 feet of the surface) occurring in a more permeable soil layer above a less permeable substrate. In the storm response of a stream, interflow provides a transition between the rapid response from surface runoff and much slower stream discharge from deeper groundwater. In some geologic settings, the distinction between "interflow" and "deep groundwater" is artificial and largely meaningless; in others, however, there is a strong physical discrimination between "shallow" and "deep" groundwater movement. Development reduces infiltration and thus interflow as discussed previously, as well as reducing the footprint of the area supporting interflow volume.

The datasets used, methodology for creating the dominant hydrologic processes maps, and the results are described in the sections below.

2.1.1. Datasets Used for identifying dominant hydrologic processes

The following datasets were used in the analysis:

Dataset	Source	Year	Description
Elevation	USGS	2013	1/3rd Arc Second (~10 meter cells) digital elevation model for San Diego County
Soils Data	SanGIS	2013	NRCS (SSURGO) Database for San Diego County downloaded from SanGIS
Land Cover	SanGIS	2013	Ecology-Vegetation layer for San Diego County downloaded from SanGIS



Dataset	Source	Year	Description
Geology	Kennedy, M.P., and Tan, S.S.	2002	Geologic Map of the Oceanside 30'x60' Quadrangle, California, California Geological Survey, Regional Geologic Map No. 2, 1:100,000 scale.
	Kennedy, M.P., and Tan, S.S.	2008	Geologic Map of the San Diego 30'x60' Quadrangle, California, California Geological Survey, Regional Geologic Map No. 3, 1:100,000 scale.
	Todd, V.R.	2004	Preliminary Geologic Map of the El Cajon 30'x60' Quadrangle, Southern California, United States Geological Survey, Southern California Aerial Mapping Project (SCAMP), Open File Report 2004-1361, 1:100,000 scale.
	Jennings et al.	2010	"Geologic Map of California," California Geological Survey, Map No. 2 – Geologic Map of California, 1:750,000 scale
Groundwater Basins	SanGIS	2013	Groundwater Basins in San Diego County downloaded from SanGIS

2.1.2. Methodology/Assumptions/Criteria for identifying dominant hydrologic processes

The methodology used to describe dominant hydrologic processes is based on recommendations included in the Southern California Coastal Water Research Project's (SCCWRP) Technical Report 605 titled "Hydromodification Screening Tools: GIS-Based Catchment Analyses of Potential Changes in Runoff and Sediment Discharge" (SCCWRP, 2010). The foundation for this analysis was to incorporate the Report's concept of grouping common hydrologic attributes into Hydrologic Response Units (HRUs). The report states the following:

> *"Grouping common hydrologic attributes across a watershed into a tractable number of Hydrologic Response Units (HRUs: a term first used by England and Holtan 1969) has become a well-established approach for condensing the near-infinite variability of a natural watershed into a tractable number of different elements. The normal procedure for developing HRUs is to identify presumptively similar rainfall–runoff characteristics across a watershed by combining spatially distributed climate, geology, soils, land use, and topographic data into areas that are approximately homogeneous in their hydrologic properties (Green and Cruise 1995, Becker and Braun 1999, Beven 2001, Haverkamp et al. 2005). As noted by Beighley et al (2005), this process of merging the landscape into discrete HRUs is a common and effective method for reducing model complexity and data requirements. Using watershed characteristics to predict runoff is the explicit task of hydrologic models, and there is a host of such models available for application to hydromodification evaluation. For purposes of "screening," however, the goal is simplicity and ease of application even if the precision of the resulting analysis is crude."*

The following process describes the methodology used to define Hydrologic Response Units (HRUs) and then relate the HRUs to the dominant hydrologic processes (i.e., overland flow, interflow, and groundwater recharge) in the 9 WMAs in San Diego County.

The first step is to define the HRUs. Once these are defined, the remaining steps determine the dominant hydrologic process.

1. **Integrate data sets used to determine HRU**: Categories for soil type, gradient, and land cover were defined based on readily available GIS datasets for the region and classifications found in relevant literature, as indicated below. The different combinations of these three categories comprise the distinct HRUs.

    - **Soil Categories**: based on National Resource Conservation Service (NRCS) Hydrologic Soil Group (HSG) classifications, which are commonly used to describe runoff/infiltration potential of soils on a regional scale. These categories include: A, B, C, and D. HSG A soils have the lowest runoff potential, while HSG D soils have the highest runoff potential.

    - **Gradient Categories**: based on slope ranges found in a review of relevant literature identified in Chapter 6. The spatial processing of the slope categories utilized the United States Geologic Survey (USGS) National Elevation Dataset (NED). Slopes were grouped (bins) into the following ranges: 0% to 2%; 2% to 6%; 6% to 10%; and greater than 10%. The 2% and 6% slope thresholds were based on slope ranges included in Table A.1.1 (McCuen, 2005) presented in Attachment A.1. This table provides runoff coefficients as a function of slope, soil group, land cover, and return period and was used for subsequent steps in the mapping effort. The 10% slope threshold was used in SCCWRP's Technical

Report 605 (SCCWRP, 2010) and is a logical cutoff since slopes steeper than 10% are assumed to be dominated by overland flow.

- **Land Cover Categories**: were defined using the Ecology Vegetation GIS map layer developed by the City of San Diego, the County of San Diego and SANDAG and downloaded from SanGIS (2013). The vegetation categories in the GIS layer were grouped (Table A.1.2 in Attachment A.1) to match the following categories used in SCCWRP's Technical Report 605 (SCCWRP, 2010): Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other (Water), and Unknown.

2. **Evaluate Land Cover**: Land cover categories for Agriculture/Grass, Forest, Scrub/Shrub and Other were related to land use categories defined in Table A.1.1 as shown in Table A.1.3 in Attachment A.1. Relating a land use category for the Developed land cover category was not necessary because all Developed cover was assumed to have overland flow as its dominant hydrologic process.
3. **Determine Hydrology Characteristics for Land Covers**: For each of the land cover/land use categories listed in Table A.1.3, the ratio of precipitation lost to evapotranspiration (i.e. an evapotranspiration coefficient) was estimated using Table A.1.1 using the process described below. Since precipitation is considered to be the sum of the resulting runoff, infiltration, and evapotranspiration, the coefficients for these three hydrologic pathways sum to one, as indicated below.

   Runoff Coefficient + Infiltration Coefficient + Evapotranspiration Coefficient = 1

   i) **Estimate Evapotranspiration**: To estimate the evapotranspiration (ET) coefficient for each land cover, first the runoff coefficient was identified in Table A.1.1 for the highest runoff potential (i.e., Group D soil and 6%+ slope) and most common storm conditions (i.e., storm recurrence intervals less than 25 years). The infiltration for these high runoff conditions was assumed to be negligible, resulting in an infiltration coefficient of zero. Since the sum of the three coefficients should sum to one, the ET coefficient was assumed to be the remaining difference (i.e., ET Coefficient = 1 – Runoff Coefficient). The ET coefficient calculated for the highest runoff potential was then applied to all soil types and slopes within that land use category. The calculated ET coefficient for each applicable HRU is provided in Table A.1.4 in Attachment A.1. The ET coefficient for HRUs that have a Developed land cover or a gradient greater than 10% were not calculated since these HRUs were assumed to have overland flow as the dominant hydrologic process.

   ii) **Estimate Infiltration**: The infiltration coefficient for each applicable HRU (i.e., combination of soil, gradient, and land cover) was estimated by subtracting both the runoff coefficient, provided in Table A.1.1, and the ET coefficient, calculated in step 3(i), from one (i.e., Infiltration Coefficient = 1 – Runoff Coefficient – ET Coefficient). The calculated infiltration coefficient for each applicable HRU is provided in Table A.1.4 in Attachment A.1.

   iii) **Estimate Runoff**: For each applicable HRU, the runoff coefficient was divided by

the infiltration coefficient to obtain a ratio representing the potential for runoff or infiltration. The higher the ratio, the greater the potential for runoff to be a more dominant hydrologic process than infiltration. Similarly, the lower the ratio, the greater the potential for infiltration to be a more dominant hydrologic process than runoff. The calculated runoff to infiltration ratios are provided in Table A.1.4 in Attachment A.1.

4. **Associate Runoff and Infiltration to HRUs**: The following designations were assigned to each applicable HRU based on the runoff to infiltration ratio (i.e., runoff coefficient/infiltration coefficient). These designations were based on best engineering judgment with the underlying assumption that if a runoff or infiltration coefficient is more than 50% greater than its counterpart, then the prevailing process is considered dominant.

    - HRUs with runoff to infiltration ratios greater than 1.5 (3:2 ratio) were assumed to have relatively high runoff and overland flow was considered its dominant hydrologic process. These HRUs are designated by the letter "O" (Overland flow is dominant process) in Tables A.1.4 and A.1.5 in Attachment A.1.

    - HRUs with runoff to infiltration ratios less than 0.67 (2:3 ratio) were assumed to have relatively high infiltration and its dominant hydrologic process was either interflow or groundwater recharge, based on analysis described in subsequent steps. These HRUs are designated by the letter "I" (Interflow is dominant process) in Tables A.1.4 and A.1.5.

    - For HRUs with runoff to infiltration ratios between, and including, 1.5 and 0.67 it was uncertain whether it was dominated by overland flow or infiltration. These HRUs are designated by the letter "U" (Dominant process is uncertain) in Tables A.1.4 and A.1.5.

    - For HRUs that have a Developed land cover or a gradient greater than 10%, the runoff to infiltration ratios were not calculated because these HRUs were assumed to have overland flow as the dominant hydrologic process. These HRUs are designated by the letter "O" (Overland flow is dominant process) in Table A.1.5.

5. **Uncertain HRUs Assignment**: For HRUs with an uncertain designation ("U") in Table A.1.5 in Attachment A.1, the underlying regional geology (Kennedy and Tan, 2002 & 2008; Todd, 2004 and Jennings et al., 2010) was used to evaluate whether overland flow or infiltration were dominant. If the underlying geology was considered impermeable, then these uncertain areas were considered to have overland flow as its dominant hydrologic process. If the underlying geology was considered permeable, then these uncertain areas were considered to be dominated by infiltration. The determination of whether a geologic unit is impermeable or permeable was based on desktop evaluation and the best professional judgment of a Certified Engineering Geologist (CEG). This analysis was performed in GIS and is illustrated in the flowchart above.

6. **Associate Infiltration HRUs with Known Groundwater Basins**: For HRUs with relatively high infiltration and have a designation of "I" in Table A.1.5 in Attachment A.1, the presence or absence of a regional groundwater basin (SanGIS, 2013) underlying these areas determined whether the dominant hydrologic process was designated as interflow or groundwater recharge. The groundwater recharge hydrologic process was assigned as dominant for those applicable areas which had an underlying groundwater basin. The interflow hydrologic process was assigned as dominant for those applicable areas which did not have an underlying groundwater basin directly below it. This analysis was performed in GIS and is illustrated in the flowchart above.
7. **Resulting HRU Data:** The resulting GIS map of dominant hydrologic processes was reviewed by engineering professionals familiar with the hydrology in the County of San Diego to confirm that the mapping is consistent with their experience working in the region.

2.1.3. Results for identifying dominant hydrologic processes

The resulting GIS map showing the spatial distribution of dominant hydrologic processes (i.e., overland flow, interflow, and groundwater recharge) within the 9 WMAs is provided in Attachment A.1. An ArcMap document which presents the results from each step of the methodology is included in Attachment C, as well as a Google Earth KMZ file. Based on this analysis, overland flow is the predominant hydrologic process in all 9 WMAs, which is consistent with the experience of engineering professionals familiar with the hydrology of the County of San Diego.

Summary of Deliverables for Dominant Hydrologic Processes

Format	Item	Description	Location
Report	Figure	"Dominant Hydrologic Processes"	Attachment A.1
GIS	Map Group Title	Hydrologic Processes	Attachment C
	Map Layer Title	Soil Land Cover Slope Hydrologic Response Unit Initial Rating Permeability Groundwater Basin Dominant Hydrologic Processes	
	Geodatabase Feature Dataset	HydrologicProcesses	
	Geodatabase Feature Class	HRUAnalysis	
	Geodatabase Geometry Type	Polygon	
KMZ [1]	KMZ File Name	Dominant Hydrologic Processes	Attachment C

[1] To enhance the utilization of this data, the Dominant Hydrological Processes map is provided in both traditional GIS file format (ESRI software license purchase required) and as a Google Earth KMZ (Keyhole Markup Language/Zipped) file that can be viewed with the free download version of Google Earth (http://www.google.com/earth/).

2.1.4. Limitations for identifying dominant hydrologic processes

The resulting GIS map layer only lists the dominant hydrological process (i.e., an HRU assigned a dominant process of overland flow can also experience small amounts of infiltration) and provides a useful, rapid framework to perform screening-level analysis that is appropriate for watershed-scale planning studies. When more precise estimates are required for a particular site and subarea it is recommended that this analysis be augmented with site-specific analysis.

2.2.Stream Characterization

For the purpose of WMAA, the Regional MS4 Permit requires a description of existing streams in the watershed, including bed material and composition, and if they are perennial or ephemeral. This analysis was prepared for 27 streams throughout the San Diego Region agreed upon by the consultant team and Copermittees. The 27 streams are listed below and are identified on the exhibit titled "Watershed Management Area Streams" located in Attachment A.2. Streams were selected to provide at least one in each WMA and at least one in each jurisdiction. There is no numeric threshold defining a "stream" for the purpose of the Regional WMAA. Throughout the Regional WMAA, the term "stream" is used as a general term to call out any of the reaches selected for analysis, regardless of watershed area, stream order, flow rate, channel size, length, or designation of "Creek" or "River" within the name.

Regional WMAA Streams:

1. Santa Margarita River
2. San Luis Rey River
3. Buena Vista Creek
4. Agua Hedionda Creek
5. San Marcos Creek
6. Encinitas Creek
7. Cottonwood Creek (Carlsbad WMA)
8. Escondido Creek
9. San Dieguito River – Reach 1
10. San Dieguito River – Reach 2
11. Lusardi Creek
12. Los Peñasquitos/Poway Creek
13. Rattlesnake Creek
14. Carroll Canyon Creek
15. Rose Creek
16. San Diego River
17. Sycamore Creek
18. Woodglen Vista Creek
19. San Vicente Creek
20. Forrester Creek
21. Chollas Creek
22. Sweetwater River – Reach 1
23. Sweetwater River – Reach 2
24. Otay River
25. Jamul/Dulzura Creek
26. Tijuana River
27. Cottonwood Creek (Tijuana WMA)

2.2.1. Datasets Used for stream characterization

The following data were referenced for the purpose of stream characterization:

- USGS National Hydrography Dataset, downloaded from USGS November 2013

- USGS 7.5-minute quadrangles, compiled image of quadrangles covering San Diego County, various dates
- Floodplains: "National Flood Hazard Layer," provided by Federal Emergency Management Agency October 2012
- Various datasets provided by Copermittees depicting existing storm water conveyance infrastructure within their jurisdictions.
- Aerial photography by Digital Globe dated 2012

2.2.2. Methodology/Assumptions/Criteria for stream characterization

The analysis was prepared by digitizing each of the 27 streams based on review of data listed above. Within the pre-existing datasets depicting streams, floodplains, or infrastructure, no single dataset included a complete, accurate alignment of each stream. Digitizing the streams based on review of all of the data listed above allowed creation of GIS linework with a continuous corrected alignment for each stream. The following data were recorded as GIS attributes for each stream as the stream was digitized:

- River name
- Reach type (engineered or natural, constrained or un-constrained)
- Bed material
- Bank material
- Hydrographic category (perennial or intermittent)

The attributes listed above were collected manually based on interpretation of the reference data. Assumptions used in making the interpretations are listed below. The ***Hydrographic Category*** section below will provide the rationale as to why perennial and intermittent were the hydrographic categories chosen for this WMAA and not perennial and ephemeral.

Note that stream classification was not prepared within areas of Federal/State/Indian lands unless data was readily available. Stream lines were prepared within these areas for continuity, but some data fields were not populated within these areas.

Reach Type

Streams were classified as either engineered or natural, and either constrained or un-constrained. See the exhibit titled, "Watershed Management Area Streams by Reach Type" in Attachment A.2. The purpose of this exercise was to identify whether the stream has been modified by human activity within the stream itself, which may include addition of crossing structures, stabilization of banks, dredging, or any other human activity. This aids the identification of physical structures including stream armoring, constrictions, grade control, and other modifications as required by the Regional MS4 Permit.

Classification of the streams as either "**engineered"** or **"natural"** was based on the following criteria:

<u>Engineered</u>

- A classification of "engineered" was assigned where the stream itself has been modified by human activity.
- All culvert/bridge/pipe crossings either provided in the Copermittees' storm water conveyance system data or clearly visible on the aerial photo have been assigned as engineered within the limits of the crossing.
- If the Copermittees did not provide storm water conveyance system data for the dirt road crossings/dip sections the streams have been assigned as engineered within the limits of the crossing. These crossings may or may not have culverts.
- If the Copermittees' storm water conveyance system data stated the facility is a detention or desilting basin, they were assigned as engineered.
- Golf courses have been assigned as engineered.
- If aerial photography showed large water bodies (lake, pond, irrigation pond, etc.) they were assigned as engineered.
- If the storm water conveyance system data provided by the Copermittees has identified the stream as "rockbs", the assumption has been made that these streams have rocks on their bottom and the sides ("bs"), and have been assigned as engineered.
- Sand mining operations have been assigned as engineered. Sand mining is an operation that is in continuous flux and does not typically result in a discrete, engineered geometry in any given channel cross section until restoration is implemented at the conclusion of the sand mining operation. It is assigned as engineered to acknowledge human alteration of the stream.

Natural

- Streams that have no apparent alteration within the stream itself by human activity have been assigned as natural.

Classification of the streams as either **"constrained"** or **"un-constrained"** was based on the following criteria:

Constrained

- All culvers/bridge/pipe crossings either provided in the Copermittees' storm water conveyance system data or clearly visible on the aerial photo have been assigned as constrained.
- If the Copermittees did not provide storm water conveyance system data for the dirt road crossings/dip sections the streams have been assigned as constrained. These crossings may or may not have culverts.
- If the Copermittees' storm water conveyance system data stated the facility is a detention or desilting basin, they were assigned as constrained.
- Golf courses have been assigned as constrained if located within the Federal Emergency Management Agency (FEMA) floodway based on the "National Flood Hazard Layer" data.

- The USGS National Hydrographic Dataset in their hydrographic category had assigned some reaches as artificial paths. In these situations and if the aerial photography shows large water bodies (lake, pond, irrigation pond, etc.) these streams have been assigned as constrained.
- Sand mining operations located within the FEMA floodway based on the "National Flood Hazard Layer" have been assigned as constrained.

Un-constrained

- Golf courses have been assigned as un-constrained if not located within the FEMA floodway based on the "National Flood Hazard Layer" data.
- Sand mining operations not located within the FEMA floodway based on the "National Flood Hazard Layer" data have been assigned un-constrained.
- If the stream is located within the FEMA floodway based on the "National Flood Hazard Layer" and there is available land in the floodway fringe (the area between the floodway and the 100-yeaer floodplain) the area has been assigned un-constrained. Note that there may be only one side or both sides of the stream with available land in the floodway fringe therefore a note was added as to which side of the stream is constrained and un-constrained.
- If the stream is located within a FEMA 100-year floodplain based on the "National Flood Hazard Layer" data with no floodway and the FEMA floodplain width is not within an existing development or bordered by roads have been assigned as un-constrained.

Bed Material and Bank Material

The following bed and bank materials were identified:

- Concrete
- Riprap
- Pipe / culvert
- Earth

The assumptions made to identify the streams bed and bank materials were based on the following criteria:

- If the data provided by the Copermittees provided information about the stream bed and bank material, the provided data was used for the bed and bank material.
- Generally the data provided by the Copermittees did not identify the crossing type (pipe, box culvert, bridge with or without piers, etc.) or the material (RCP, RCB, earth, riprap, concrete, etc.). In that case, all culvert/bridge/pipe crossings were assigned as pipe/culvert for the bed and bank material.
- If the Copermittees did not provide data for the dirt road crossings/dip sections the bed and bank material have been assigned as pipe/culvert. These crossings may or may not have culverts.

- If the Copermittees' storm water conveyance system data stated the facility is a detention or desilting basin, the bed and bank material have been assigned as earth.
- If aerial photography showed large water bodies (lake, pond, irrigation pond, etc.) they were assigned as earth bed and bank material. The USGS National Hydrographic Dataset in their hydrographic category had assigned some of these types of reaches as artificial paths.
- Sand mining operations within the stream have been assigned as earth for bed and bank material.
- If the Copermittees did not provide data for the stream material the bed and bank material have been assigned based on the aerial photography.

See exhibits titled, "Watershed Management Area Streams by Bed Material" in Attachment A.2.

After stream bed and bank material was classified, earthen reaches were further classified by geologic group. This was accomplished by intersecting the streams with the geologic group layer that had been prepared for use in the dominant hydrologic process and potential coarse sediment yield analyses. The result is displayed in exhibits titled, "Watershed Management Area Streams by Geologic Group" in Attachment A.2.

Hydrographic Category

Streams were classified as "perennial" or "intermittent." See exhibits titled, "Watershed Management Area Streams by Hydrographic Category" in Attachment A.2. Classification was obtained from the USGS National Hydrography Dataset (NHD). The definitions of these categories in the USGS National Hydrography Dataset are:

- **Perennial**: Contains water throughout the year, except for infrequent periods of severe drought.
- **Intermittent**: Contains water for only part of the year, but more than just after rainstorms and at snowmelt.

While the specific Regional MS4 Permit language requested classification of perennial or ephemeral, rather than perennial or intermittent, the data that was referenced in order to classify streams did not include "ephemeral" streams. For reference, the USGS National Hydrography Dataset definition of "ephemeral" is: "contains water only during or after a local rainstorm or heavy snowmelt." None of the stream reaches in the study were classified as ephemeral in the NHD dataset, therefore none are classified as ephemeral in the WMAA product. The City of San Diego provided a map titled "City of San Diego Stream Survey" dated April 3, 2013 prepared by AMEC that shows streams that are "dry" and streams that are "flowing". This information in conjunction with the other parameters listed in this section was used to determine if a stream was perennial or intermittent.

USGS NHD includes hydrographic category classification for many of the streams. However data was not available for all reaches of all streams. In order to classify reaches of streams that did not already contain this data in NHD, these assumptions were made:

- The USGS NHD information for the stream hydrographic category has been used when available.
- When USGS NHD has "artificial paths" for portions of the stream, the hydrographic category of the upstream portion of the stream have been assigned to the stream unless other assumptions took precedence.
- If aerial photography shows large waterbody (lake, pond, irrigation pond, etc.) perennial has been assumed for the hydrographic category.
- For ponded areas shown on the aerial photography and if the USGS 7.5-minute quadrangles shows cross hatching for the area, intermittent has been assigned unless the upstream portion of the stream was assigned as perennial pursuant to the USGS National Hydrography Dataset then assigned perennial for the ponded area.
- USGS has a dashed line for intermittent streams. USGS has a solid line for perennial streams. In some situations this information was used to assist in the determination of assigning perennial or intermittent to a stream.

2.2.3. Results for stream characterization

The 27 streams and data are contained in a GIS file titled "SD_Regional_WMAA_Streams" located in Attachment C. The streams are shown in watershed maps included in Attachment A.2.

Summary of Deliverables for Stream Characterization

Format	Item	Description	Location
Report	Title of Figures	• "Watershed Management Area Streams" • "Watershed Management Area Streams by Hydrographic Category" • "Watershed Management Area Streams by Bed Material" • "Watershed Management Area Streams by Geologic Group" • "Watershed Management Area Streams by Reach Type"	Attachment A.2
GIS	Map Group Title	Not Grouped	Attachment C
	Map Layer Title	SD_Regional_WMAA_Streams	
	Geodatabase Feature Dataset	Streams	
	Geodatabase Feature Class	SD_Regional_WMAA_Streams	
	Geodatabase Geometry Type	Line	
KMZ [1]	KMZ File Name	SD_Regional_WMAA_Streams	Attachment C

[1] To enhance the utilization of this data, the Stream Characterization map is provided in both traditional GIS file format (ESRI software license purchase required) and as a Google Earth KMZ (Keyhole Markup Language/Zipped) file that can be viewed with the free download version of Google Earth (http://www.google.com/earth/).

In addition to the 27 streams that were subject of detailed analysis, NHD streams have been included on maps and within the geodatabase for reference. The NHD stream alignments have not been corrected and in some cases may be inconsistent with the existing infrastructure. The NHD streams are contained in a GIS file titled, "SD_NHD_Streams."

2.2.4. Limitations for stream characterization

- Only a desktop analysis was performed and no field verification was conducted.
- Infrastructure is only based on storm water conveyance system data provided by Copermittees or clearly visible on aerial photography. If the Copermittee used a numbering or lettering system for describing bed and bank material for example, since the metadata was not provided the bed and bank material could not be verified.
- In some instances concrete channels cannot be identified on aerial photography if it is filled with sediment and/ or vegetation.

2.3.Land Uses

For the purpose of the WMAA, the Regional MS4 Permit requires a description of current and anticipated future land uses. This is presented in the final GIS deliverable as "Land Use Planning" and includes the following representations of land uses in the watersheds: existing land uses, planned land uses, developable lands, redevelopment and infill areas, floodplains, Multiple Species Conservation Program (MSCP) designated areas, and areas not within the Copermittees' jurisdictions (tribal lands, state lands, and federal lands).

2.3.1. Datasets Used for land uses

The following existing regional datasets were referenced to meet this requirement:

- Municipal boundaries: "Municipal_Boundaries" dated August 2012, available from SanGIS/SANDAG
- Ownership: "Parcels" dated December 2013, available from SanGIS/SANDAG
- Existing land use: "SANGIS.LANDUSE_CURRENT" dated December 2012, available from SanGIS/SANDAG (existing land use)
- Planned land use: "PLANLU" (Planned Land Use for the Series 12 Regional Growth Forecast (2050)), dated December 2010, available from SanGIS/SANDAG
- Developable land: "DEVABLE" (Land available for potential development for the Series 12 Regional Growth Forecast), dated December 2010, available from SanGIS/SANDAG
- Redevelopment and infill areas: "REDEVINF" (Redevelopment and infill areas for the Series 12 Regional Growth Forecast), dated December 2010, available from SanGIS/SANDAG
- Floodplains: "National Flood Hazard Layer" provided by Federal Emergency Management Agency October 2012
- Multiple Species Conservation Program (MSCP), total of four datasets available from SanGIS/SANDAG: "MHPA_SD," dated 2012, (Multiple Habitat Planning Areas for City of San Diego); "MSCP_CN," dated 2009 (designations of the County of San Diego's Multiple Species Conservation Program South County Subregional Plan); "MSCP_EAST_DRAFT_CN," dated 2009 (draft East County MSCP Plan); and "Draft_North_County_MSCP_Version_8.0_Categories," dated 2008 (draft North County MSCP Plan)

2.3.2. Methodology/Assumptions/Criteria for land uses

The existing regional datasets for existing land use, planned land use, developable land, redevelopment and infill areas, floodplains, and MSCP designated areas were referenced with no modifications. Areas not within the Copermittees' jurisdictions (tribal lands, state lands, and federal lands) were compiled from SanGIS parcel data (December 2013) based on the "ownership" value. The owners listed below were excluded from the Copermittees jurisdictions and represent the "Federal/State/Indian" layer, which is displayed on various maps included in Attachment A.2.

- Bureau of Land Management
- California Department of Fish and Game
- Indian Reservations
- Military Reservations

- Other Federal
- State
- State of California Land Commission
- State Parks
- U.S. Fish and Wildlife Service
- U.S. Forest Service

When available, relevant data from these areas was included in analyses (e.g., developable land areas within Federal/State/Indian areas). Stream lines were prepared within these areas for continuity. However, stream classification (e.g., bed and bank material) was not prepared within these areas unless data was readily available (e.g., hydrographic category data available from NHD)

2.3.3. Results for land uses

The existing regional datasets are compiled into the Geodatabase in a group titled, "Land Use Planning." Current and anticipated future land uses are depicted in watershed maps included in Attachment C. Federal/State/Indian Lands are also referenced on all other map exhibits included in Attachment A.2.

Summary of Deliverables for Land Uses

KMZ [1]	KMZ File Name	Municipal Boundaries Federal/State/Indian Lands Floodplains Due to file size limitations, SanGIS land use datasets were not converted to KMZ.	Attachment C

[1] To enhance the utilization of this data, the Land Uses map is provided in both traditional GIS file format (ESRI software license purchase required) and as a Google Earth KMZ (Keyhole Markup Language/Zipped) file that can be viewed with the free download version of Google Earth (http://www.google.com/earth/).

2.3.4. Limitations

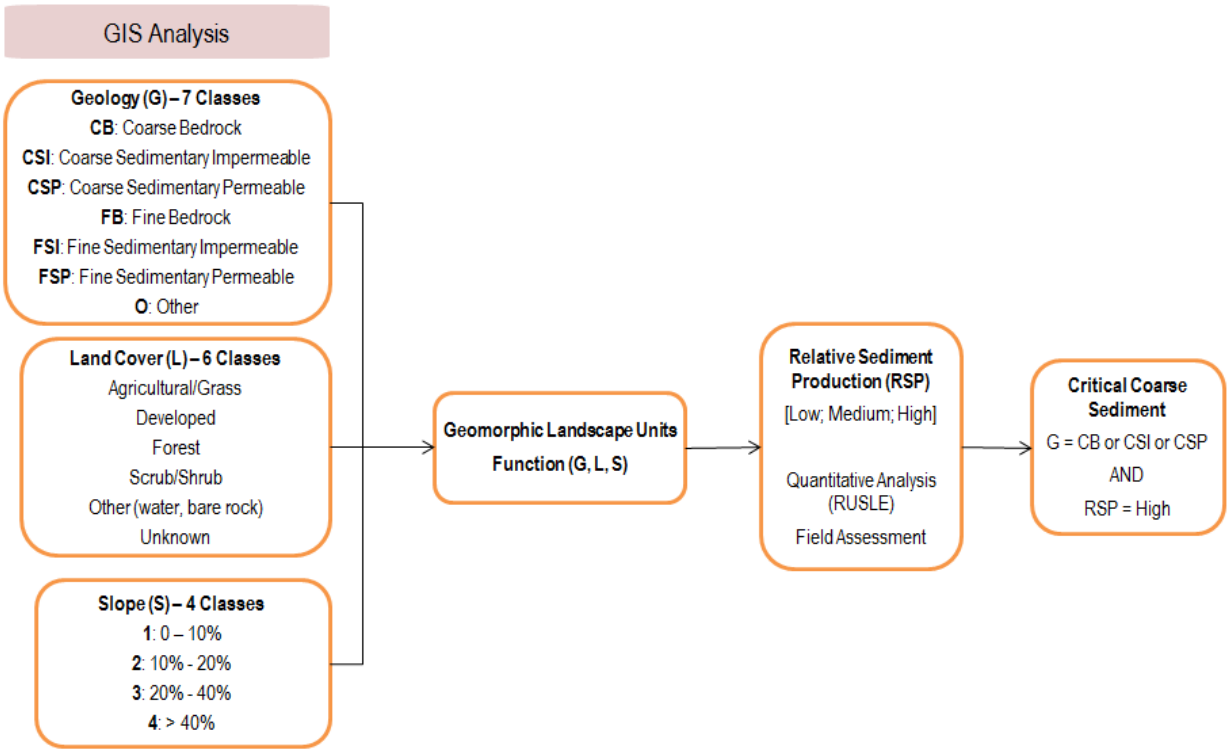
Some jurisdictions may have compiled GIS land use layers that include more detailed or more current information than the regional datasets available from SanGIS. SanGIS layers were selected for the Regional WMAA to provide consistent land use characterization region-wide, and to provide for repeatability of GIS analyses when a land use layer is required for input data. The definition of non-Copermittee areas identified in this document as "Federal/State/Indian Lands" is for the Regional WMAA. Some WQIPs may define non-Copermittee areas differently.

2.4.Potential Critical Coarse Sediment Yield Areas

The Regional MS4 Permit identifies in the provisions related to the WMAA that potential coarse sediment yield areas within the watershed be identified, with GIS layers (maps) as output. With regard to the function and importance of coarse sediment, SCCWRP Technical Report 667 titled "Hydromodification Assessment and Management in California" states the following:

"Coarse sediment functions to naturally armor the stream bed and reduce the erosive forces associated with high flows. Absence of coarse sediment often results in erosion of in-channel substrate during high flows. In addition, coarse sediment contributes to formation of in-channel habitats necessary to support native flora and fauna."

This report identifies the potential critical coarse sediment yield areas for the 9 WMAs in compliance with this permit provision. The applied datasets and methodologies for identifying the coarse sediment yield areas, along with their respective results, are described in the sections below.



2.4.1. Datasets Used for identifying potential critical coarse sediment yield areas

The following datasets were used in the analysis

Dataset	Source	Year	Description
Elevation	USGS	2013	1/3rd Arc Second (~10 meter cells) digital elevation model for San Diego County
Land Cover	SanGIS	2013	Ecology-Vegetation layer for San Diego County downloaded from SanGIS
Geology	Kennedy, M.P., and Tan, S.S.	2002	Geologic Map of the Oceanside 30'x60' Quadrangle, California, California Geological Survey, Regional Geologic Map No. 2, 1:100,000 scale.
	Kennedy, M.P., and Tan, S.S.	2008	Geologic Map of the San Diego 30'x60' Quadrangle, California, California Geological Survey, Regional Geologic Map No. 3, 1:100,000 scale.
	Todd, V.R.	2004	Preliminary Geologic Map of the El Cajon 30'x60' Quadrangle, Southern California, United States Geological Survey, Southern California Areal Mapping Project (SCAMP), Open File Report 2004-1361, 1:100,000 scale.
	Jennings et al.	2010	"Geologic Map of California," California Geological Survey, Map No. 2 – Geologic Map of California, 1:750,000 scale

2.4.2. Methodology/Assumptions/Criteria for identifying potential critical coarse sediment yield areas

The methodology used to identify coarse sediment yield areas is based on Geomorphic Landscape Unit (GLU) methodology presented in the SCCWRP Technical Report 605 titled "Hydromodification Screening Tools: GIS-Based Catchment Analyses of Potential Changes in Runoff and Sediment Discharge" (SCCWRP, 2010). Geomorphic Landscape Units characterize the magnitude of sediment production from areas through three factors judged to exert the greatest influence on the variability on sediment-production rates: geology types, hillslope gradient, and land cover. The GLU approach provides a useful, rapid framework to identify sediment-delivery attributes of the watershed. The process to integrate these factors into GLUs is indicated in the flow chart below.

The following steps were used to define Geomorphic Landscape Units (GLUs), which were then related to the coarse sediment and critical coarse sediment yield areas in the 9 WMAs in San Diego County.

1. **Integrate data sets used to determine GLU:** Categories for geology, gradient, and land cover were defined based on readily available GIS datasets for the region and classifications found in relevant literature listed in Chapter 6. The different combinations of these categories make up distinct GLUs.

    - **Geologic Categories**: based on methodology listed in Attachment A.4.1 of Attachment A.4. Resulting geologic categories from this analysis are: Coarse Bedrock (CB), Coarse Sedimentary Impermeable (CSI), Coarse Sedimentary Permeable (CSP), Fine Bedrock (FB), Fine Sedimentary Impermeable (FSI), Fine Sedimentary

Permeable (FSP), and Other (O). An exhibit showing the regional geology groupings is presented in Attachment A.4.

- **Land cover categories**: defined using the Ecology Vegetation GIS map layer developed by the City of San Diego, the County of San Diego and SANDAG which were downloaded from SanGIS (2013). The vegetation categories in the GIS layer were grouped (Table A.1.2 in Attachment A.1) to match the following categories used in SCCWRP's Technical Report 605 (SCCWRP, 2010): Agriculture/Grass; Developed; Forest; Scrub/Shrub, Other (Water) and Unknown.
- **Gradient Categories**: based on slope ranges found in a review of relevant literature (GLU methodology applied in California) listed in Chapter 6. The spatial processing of the slope categories utilized the USGS National Elevation Dataset (NED). Slope ranges used include: 0% to 10%, 10% to 20%, 20% to 40%, and greater than 40%.

2. **GLU Union Results**: GIS mapping exercise for the study area resulted in 166 GLUs within the 9 WMAs in San Diego County. Table A.4.2 in Attachment A.4 provides the list of the 166 GLUs.

For implementing hydromodification management performance standards in the Regional MS4 Permit, the Copermittees need to identify Critical Coarse Sediment Yield areas in the study region. To provide information on the identification of Critical Coarse Sediment yield, the study assumed that critical coarse sediment would be generated from GLUs that are composed of geologic units likely to generate coarse sediment (based on the methodology listed in Step 3) and have the potential for high relative sediment production (as estimated using the methodology listed in Step 4).

3. **Define Pertinent Geologic groups**: the geologic groups (Attachment A.4.1) considered in this study to have the potential to generate coarse sediment are Coarse Bedrock (CB), Coarse Sedimentary Impermeable (CSI), and Coarse Sedimentary Permeable (CSP). An exhibit showing the regional geologic grouping is presented in Attachment A.4.
4. **Relate GLU to Sediment Production**: For assigning GLUs with a relative sediment production, the following methodology was utilized:
    - Conducted quantitative analysis to assign relative sediment production. Analysis was performed based on the assumption that sediment production from an area is proportional to the soil loss from the area, as evaluated using standard soil loss equation. Detailed analysis steps are documented in Attachment A.4.2;
    - To validate the quantitative assignment above, a qualitative field assessment was conducted for 40 sites. Site selection and findings from the field assessment is documented in Attachment A.4.3.
    - The result of the field assessment indicated a 65% match between field conditions and the quantitative assignments. The mismatches are attributed to differences in percent land cover as assumed for the quantitative analysis and those observed in the field. As such, the quantitative assignments were considered to be valid for the purposes of assigning relative sediment production.

2.4.3. Results for identifying potential critical coarse sediment yield areas

The resulting GIS maps showing the spatial distribution of geologic grouping and critical coarse sediment yield areas within the 9 WMAs in San Diego Region are provided in Attachment A.4. An ArcMap document which presents the results from each step of the methodology is included in Attachment C. Based on this analysis it was estimated that 82% of the study area is a potential coarse sediment yield area and 20% of the study area is a potential critical coarse sediment yield area. The majority of the potential critical coarse sediment yield areas were identified to be on slopes greater than 25% and/or on federal/state lands.

As a result of the regional-scale datasets, and commensurate data resolution, used to map the potential critical coarse sediment yield areas, some areas may have been mapped that in reality do not produce critical coarse sediment as they are existing developed areas. As such, an opportunity for jurisdictions to incorporate more refined data into the preliminary WMAA GIS dataset based on local knowledge and review of current aerial images was provided. The City of Escondido, the City of Encinitas, the City of Del Mar, the City of Poway, National City, and the County of San Diego provided augmented data in their respective jurisdictional areas.

Summary of Deliverables for Potential Critical Coarse Sediment Yield Areas

Format	Item	Description	Location

	Map Layer Title	Geologic Grouping Land Cover Slope Category Geomorphic Landscape Unit Potential Coarse Sediment Yield Area Relative Sediment Production Potential Critical Coarse Sediment Yield Area	
	Geodatabase Feature Dataset	PotentialCoarseSedimentYield	
	Geodatabase Feature Class	GLUAnalysis PotentialCoarseSedimentYieldAreas PotentialCriticalCoarseSedimentYieldAreas	
	Geodatabase Geometry Type	Polygon	
KMZ [1]	KMZ File Name	Potential Critical Coarse Sediment Yield Areas	Attachment C

[1] To enhance the utilization of this data, the Geomorphic Landscape Unit Analysis is provided in both traditional GIS file format (ESRI software license purchase required) and as a Google Earth KMZ (Keyhole Markup Language/Zipped) file that can be viewed with the free download version of Google Earth (http://www.google.com/earth/).

2.4.4. Limitations for identifying potential critical coarse sediment yield areas

The resulting GIS layers were developed using regional datasets and provide a useful, rapid

framework to perform screening-level analysis that is appropriate for watershed-scale planning studies. The methodology used to identify potential coarse sediment yield areas does not account for instream sediment supply and sediment production from mass failures like landslides which are difficult to estimate on a regional scale without performing extensive field investigation. This data set also does not account for potential existing impediments that may hinder delivery of coarse sediment to receiving waters or downstream locations within the watershed as this was beyond the scope of a regional study. Where more precise estimates are required for a particular site or subarea it is recommended that this analysis be augmented with site-specific analysis. It is also recognized that this regional data set is a function of the inherent data resolution and therefore may not conform to all site conditions, or does not reflect changes to particular areas that have occurred since the underlying data was developed. As such, the Regional WMAA data for the potential critical coarse sediment yield areas should be verified in the field according to the procedures outlined in the Model BMP Design Manual and/or jurisdiction specific BMP Design Manual.

2.5.Physical Structures

The Regional MS4 Permit requires the Copermittees to identify information regarding locations of existing flood control structures and channel structures, such as stream armoring, constrictions, grade control structures, and hydromodification or flood management basins with GIS layers (maps) as output, for each WMA being analyzed for the purpose of developing watershed-specific requirements for structural BMP implementation. This study identified the physical structures using a desktop-level analysis for the 27 streams identified in Section 2.2 in the 9 WMAs in compliance with this permit provision.

2.5.1. Approach for identifying physical structures

The intent of this portion of the WMAA project was to provide an initial assessment of the structures of interest for the 27 river reaches identified in Section 2.2. This desktop-level analysis was conducted primarily as a visual survey of aerial imagery and FEMA flood insurance study (FIS) profiles where available. The collected information was entered into a GIS layer for inclusion into the overall WMAA geodatabase containing the characterization layers required by the Regional MS4 Permit. To support overall WMA characterization, the information derived in this task provides insight into water and sediment movement through the watershed (SCCWRP, 2012), the opportunities and limitations for infrastructure retrofits and also informs efforts to identify appropriate locations for habitat or riparian area rehabilitation in relation to proximate infrastructure. Specific information regarding how the survey was performed and the attributes of the generated data is presented in Attachment A.5. Note that concrete channels, pipes/culverts, riprap or other artificial stream armoring, and basins have also been identified in the linework generated for the 27 streams (see Section 2.2).

2.5.2. Results for identifying physical structures

The resulting GIS maps showing the spatial locations of the physical structures within the 9 WMAs are provided in Attachment A.5.

Summary of Deliverables for Physical Structures

	Geodatabase Feature Class	ChannelStructures	
	Geodatabase Geometry Type	Point	
KMZ [1]	Kmz File Name	ChannelStructures	Attachment C

[1] To enhance the utilization of this data, the Physical Structures map is provided in both traditional GIS file format (ESRI software license purchase required) and as a Google Earth KMZ (Keyhole Markup Language/Zipped) file that can be viewed with the free download version of Google Earth (http://www.google.com/earth/).

3. Template for Candidate Project List

The Regional MS4 Permit requires each WMA to use the results from the WMA characterization to compile a list of candidate projects that could potentially be used as alternative compliance options for Priority Development Projects should an agency or jurisdiction opt to develop an alternative compliance program. Copermittees must first conclude that implementing such a candidate project would provide greater overall benefit to the watershed than requiring implementation of structural BMPs onsite prior to implementing these candidate projects as alternative compliance projects.

The Copermittees elected to identify potential candidate projects as a separate effort from this regional project, and therefore the process for identifying candidate projects is not documented in this report. Instead, this project only developed a template, in a spreadsheet format, for use by the Copermittees to compile lists of potential candidate projects. The template is intended to enhance regional consistency of the information that is gathered for candidate projects. The template spreadsheet file was distributed to the Copermittees on January 28, 2014. A table of the template components is indicated below:

Column	Primary Heading	Secondary Heading	Guidance for Completing the Project List
A	Project Identifier	-	Unique identifier for the project.
B	Watershed Management Area	-	Dropdown menu to select the watershed management area the project is located in
C	Hydrologic Area (HA)	-	Dropdown menu to select the hydrologic area the project is located in Select a WMA in column B for HA (Column C) dropdown menu to activate.
D	Hydrologic Subarea (HSA)	-	Dropdown menu to select the hydrologic subarea the project is located in. Select a HA in column C for HSA (Column D) dropdown menu to activate.
E	Jurisdiction	-	Dropdown menu to select the jurisdiction the project is located in. Select a HSA in column D for Jurisdiction (Column E) dropdown menu to activate.
F	Project Name	-	Indicate the name of the project.
G	Ownership	Type	Dropdown menu to select if the project is a public project, private project, or public-private partnership.
H	Ownership	Ownership Information	List the details for the owner.
I	Project Location	Address	List the address of the project site.
J	Project Location	APN	List the APN of the parcel.
K	Project Location	Latitude	List the latitude of the project site.
L	Project Location	Longitude	List the longitude of the project site.

Column	Primary Heading	Secondary Heading	Guidance for Completing the Project List
M	Project Origination/ Originator	Name	List the name of the report/organization/individual that provided the idea for the project. Potential origination sources: WQIP, WMAA, JURMPs, WURMPs, CLRPs, IRWM, MSCP, MHPA, Other.
N	Project Origination/ Originator	Contact Information	Link or report title if the proposed project is from a report [or] contact information if from an organization/individual.
O	Project Category	-	Drop Down menu to select the project category; In addition to the 6 project categories explicitly listed in the Regional MS4 Permit, the drop down menu also has a category "Other project types allowed by the MS4 Permit". Example for “Other” project types are agency CIP programs such as Green Streets, LID conversions (medians, parks), agency filter installation, etc.
P	Specific Project Type	-	List the subcategory of the project; for example, list Regional BMP type (i.e. infiltration basin, wetland, etc.).
Q	Potential Pollutant	-	Identify the potential pollutant(s) that can be treated by the proposed project.
R	Project Size & Parameters	Contributing Drainage Area (acres)	List the contributing drainage area to the project.
S	Project Size & Parameters	Parcel Size (acres)	List the size of the parcel the project is located on.
T	Project Size & Parameters	Project Footprint (acres)	List the size of the project footprint.
U	Project Size & Parameters	Parameters (with units as necessary)	Parameters needed to quantify benefits from the project; i.e. for an infiltration basin, list the water quality volume, long-term infiltration rate, depth of the basin, etc.
V	Regulatory Requirement	-	Indicate if the project is proposed to meet particular regulatory requirement such as TMDL, etc.
W	Project Timeline	-	Indicate if a project must be implemented by certain date to meet a grant deadline or other time commitment.
X	Other Notes	-	List any other relevant notes; for example, when retrofitting existing infrastructure project category is selected, input parameters needed to quantify benefits from existing infrastructure into this column as these will be needed to estimate additional benefits that can be used for alternative compliance. If N/A is selected in any dropdown menus, add additional explanation in here

4. Hydromodification Management Applicability/Exemptions

Hydromodification, which is caused by both altered storm water flow and altered sediment flow regimes, is largely responsible for degradation of creeks, streams, and associated habitats in the San Diego Region. The purpose of the hydromodification management requirements in the Regional MS4 Permit is to maintain or restore more natural hydrologic flow regimes to prevent accelerated, unnatural erosion in downstream receiving waters.

The Regional MS4 Permit allows exemptions at the discretion of the local agencyfor priority development projects that discharge runoff to receiving waters that are not susceptible to erosion (e.g., a reservoir, lake, enclosed embayment, or the Pacific Ocean) either directly or via hardened systems including concrete-lined channels or existing underground storm drain systems.

The March 2011 Final Hydromodification Management Plan (HMP) identified certain exemptions from hydromodification management requirements by presenting "HMP applicability criteria." The Regional MS4 Permit maintains some of these HMP applicability criteria. However, some of the applicability criteria are not included under the Regional MS4 Permit unless the area or receiving water is mapped in the WMAA. The intent of this Section is to provide supporting technical analyses for exemptions that are recommended by the WMAA, and to provide mapping of areas exempt from hydromodification management requirements.

4.1.Additional Analysis for Hydromodification Management Exemptions

This section documents additional analysis performed to further evaluate the following exemptions that were already approved by the San Diego Regional Board with the 2011 Final HMP. This study only provides additional analysis, data, and rationale for supporting or eliminating the following existing exemptions and does not propose or study any new exemptions.

- Exempt River Reaches
- Stabilized Conveyance Systems Draining to Exempt Water Bodies
- Highly Impervious Watersheds and Urban Infill and
- Tidally Influenced Lagoons

4.1.1. Exempt River Reaches

4.1.1.1. History

The March 2011 Final HMP, approved by the SDRWQCB under the 2007 MS4 Permit, provided a potential exemption from hydromodification management requirements for projects discharging runoff directly to certain major river reaches, provided that the outlet elevation of the project's outfall(s) to an identified exempt river reach are between the river bottom elevation and the 100-year floodplain elevation, and properly sized energy dissipation is provided at the outfall(s).

Exempt river systems/reaches from the 2011 Final HMP:

River	Downstream Limit	Upstream Limit
Otay River	Outfall to San Diego Bay	Lower Otay Reservoir Dam
San Diego River	Outfall to Pacific Ocean	Confluence with San Vicente Creek
San Dieguito River	Outfall to Pacific Ocean	Lake Hodges Dam
San Luis Rey River	Outfall to Pacific Ocean	Upstream river limit of Basin Plan subwatershed 903.1 upstream of Bonsall and near Interstate 15
Sweetwater River	Outfall to San Diego Bay	Sweetwater Reservoir Dam

Exemptions related to runoff discharging directly to the above river reaches were based on the flow duration analysis performed for the San Diego River in the Final HMP and the Technical Advisory Committee (formed to provide input on the development of the Final HMP) members' opinion (based on field observations and years of historical perspective) that the above river reaches have very low gradients, were depositional (aggrading), have very wide floodplain areas when in the natural condition and that the effects of cumulative watershed impacts to these reaches is minimal provided that properly sized energy dissipation is provided at outfalls to the rivers.

4.1.1.2. Status under 2013 Regional MS4 Permit

Under the Regional MS4 Permit, exempt river reaches would not qualify for exemption from hydromodification management controls unless the optional WMAA is developed with additional rationale/analyses to support reinstating exemptions to these river reaches. Additional analysis performed as part of the WMAA to evaluate hydromodification management control exemptions to the previously exempt reaches is presented below.

4.1.1.3. Research, Approach and Results

Hydromodification impacts can be caused due to increase in flows, changes in sediment transport capacity and changes in sediment supply to the streams (SCCWRP, 2012). In order to evaluate the cumulative impacts due to development and determine if hydromodification management control exemptions can be reinstated for the river reaches that were exempt in the previous permit term, erosion potential (Ep) analysis was used to evaluate the increase in flows and changes in sediment transport capacity. In addition, sediment supply potential (Sp) analysis was used to evaluate the changes in sediment supply in this study. In regards to Ep analysis

SCCWRP Technical Report 667 "Hydromodification Assessment and Management in California" states:

> *"The underlying premise of the erosion potential approach advances the concept of flow duration control by addressing in-stream processes related to sediment transport. An erosion potential calculation combines flow parameters with stream geometry to assess long term (decadal) changes in the sediment transport capacity. The cumulative distribution of shear stress, specific stream power and sediment transport capacity across the entire range of relevant flows can be calculated and expressed using an erosion potential metric, Ep (e.g., Bledsoe, 2002)."*

The approach used in this study is explained in detail in Attachment B.1.1.1. The following WMA characterization maps developed in Section 2 were used to select inputs for the exempt river reach analysis:

- Planning land use layers from Section 2.3 were used to estimate the existing impervious area and identify the developable parcels in each watershed. A GIS exercise was performed to identify the developable parcels in each watershed that will be exempt from hydromodification management requirements if the exemption is granted.
- Stream type classification analysis from Section 2.2 was used to select a conservative cross section (segments that are assigned naturally constrained) to be used in analysis for each watershed.
- GLU analysis and its associated quantitative analysis described in Section 2.4 were used to determine Sp metric for each watershed. In this study coarse sediment supply changes were limited to changes in hill slope erosion between existing condition and future condition (for parcels that are proposed to be exempt from hydromodification management) of the watershed. It was assumed that the changes in instream sediment supply between existing and future condition for these large depositional river systems are very minimal.

Selection of inputs for the analysis is explained in detail in Attachment B.1.1.2 and results from the analysis are presented in Attachment B.1.1.3 in tabular format. The Ep analysis performed in this study does not account for the following Regional MS4 permit requirements as a conservative assumption. If accounted for, it will result in a smaller Ep than what is currently reported in Attachment B.1.1.3:

- New development priority development projects including projects that are proposed to be exempt from hydromodification management requirements through this WMAA study must implement retention BMPs to the extent feasible if alternative compliance option is not selected or not available.
- Redevelopment priority development projects must mitigate to the pre-developed condition.

4.1.1.4. Recommendation

Based on the results from this study reported in Attachment B.1.1.3, the flow duration analysis performed in the Final HMP, and the Technical Advisory Committee (TAC) recommendations provided during the Final HMP development, it is recommended that hydromodification

management exemption be reinstated for projects discharging runoff directly to the following exempt river reaches:

River	Downstream Limit	Upstream Limit
Otay River	Outfall to San Diego Bay	Interstate 805
San Diego River	Outfall to Pacific Ocean	Confluence with San Vicente Creek
San Dieguito River	Upstream edge of the railroad crossing	Lake Hodges Dam
San Luis Rey River	Outfall to Pacific Ocean	Upstream river limit of Basin Plan subwatershed 903.1 upstream of Bonsall and near Interstate 15
Sweetwater River	Outfall to San Diego Bay	Sweetwater Reservoir Dam

Each municipality must define/approve "direct discharge" based on the project site conditions. To qualify for the potential exemption, the outlet elevation must be between the river bottom elevation and the 100-year floodplain elevation and properly designed energy dissipation must be provided. Mapping of these exempt river reaches is presented in Attachment B.2.

Additional studies to establish a site-specific allowable Ep metric for the Otay River from east of Interstate 805 to Lower Otay Reservoir Dam, more closely representing actual measured and observed characteristics of this river system, may result in allowing hydromodification management exemptions not currently supported by this desktop assessment which was based on an allowable Ep metric from literature. However, any future proposed HMP exemptions would need to be approved through the WQIP Annual Update process (Regional MS4 Permit Section F.1.2.c.).

4.1.1.5. Limitations

The analysis and associated recommendations as presented above were based on instream erosion as the primary consideration to support reinstatement of exemptions from hydromodification management controls for discharges directly to these river reaches. While it is recognized that other factors contribute to adverse impacts (e.g., salinity imbalance, pollutants) to instream habitat and resulting biotic integrity, hydromodification management control has traditionally been considered an "umbrella process" that encompasses most of the highest risk stressors (percent sands and fines present, channel alteration, and riparian disturbance) to physical habitat. Beyond demonstrating that instream erosion is not anticipated as a result of reinstating hydromodification management control exemptions for discharges to these river reaches, a focused method for correlating physical and biotic integrity to modified hydrological conditions has not been performed in this analysis, as an assessment method has not yet been developed.

The current assessment methods may yield inconclusive results when attempting to identify causal relationships between degraded instream habitat solely due to increased flows and erosive force from hydromodification. A causal assessment recently conducted in the lower reaches of the San Diego River, conducted as a partnership between the Southern California Coastal Water

Research Project (SCCWRP), the City of San Diego, the County of San Diego, and the San Diego RWQCB, focused on stressors potentially responsible for known biological impairment of the river. Once the data of the causal assessment become available, it may be useful in classifying the potential stressors such as altered physical habitat as likely, unlikely, or an uncertain cause to biological impairment.

With respect to adverse impacts to habitat as a result of pollutants entrained in storm water discharges, these areas will still be subject over time to the pollutant control requirements of the Regional MS4 Permit as areas develop or redevelop. The current requirements obligate development to maximize retention of the design storm volume which will mitigate a portion of the volume that would otherwise be controlled with hydromodification management BMPs. In some cases, this offsetting of volume reduction through pollutant control BMPs may exceed the HMP volumes. In addition, the development that occurs within the exempted watershed areas is still required to provide any applicable flood control measures. Risk of flooding as a result of exemption from hydromodification controls is unlikely as the control thresholds are significantly lower (order of magnitude) than flood control requirements implemented to protect life and property.

4.1.2. Stabilized Conveyance Systems Draining to Exempt Water Bodies

4.1.2.1. History

The March 2011 Final HMP, approved by the SDRWQCB under the 2007 MS4 Permit, provided a potential exemption from hydromodification management requirements for projects discharging runoff directly to hardened or rehabilitated systems that extend to exempt receiving waters. As described in the HMP, hardened or rehabilitated systems could include existing storm drain systems, existing concrete channels, or stable engineered unlined channels. To qualify for this exemption, the existing hardened or rehabilitated conveyance system must continue uninterrupted to the exempt system. In other words, the hardened or rehabilitated conveyance system cannot discharge to an unlined, non-engineered channel segment prior to discharge to the exempt system. Additionally, the project proponent must demonstrate that the hardened or rehabilitated conveyance system has capacity to convey the 10-year ultimate condition flow through the conveyance system. The 10-year flow should be calculated based upon single-event hydrologic criteria as detailed in the San Diego County Hydrology Manual.

This exemption was consistent with 2007 MS4 Permit language allowing exemption for discharges into "channels that are concrete-lined or significantly hardened (e.g., with rip-rap, sackrete, etc.) downstream to their outfall in bays or the ocean." The HMP language also allowed for channels stabilized by soft methods such as turf reinforcement mat or vegetation to be considered for exemption. Under these criteria, an engineered channel that is stabilized with riprap, turf reinforcement mat, vegetation, or other materials other than concrete could be determined to be exempt from hydromodification management requirements, pending demonstrating that it has capacity to convey the 10-year ultimate condition flow.

4.1.2.2. Status under 2013 Regional MS4 Permit

A significant change under the Regional MS4 Permit is the requirement that exempt systems draining to exempt water bodies either be "existing underground storm drain systems," or "conveyance channels whose bed and banks are concrete lined" all the way to exempt water bodies. The Regional MS4 Permit language does not include engineered channels that are stabilized with materials other than concrete, such as riprap, turf reinforcement mat, or vegetation. However, areas identified by Copermittees as appropriate for an exemption may be identified in the optional WMAA incorporated into the WQIP.

4.1.2.3. Research and Results

To provide a process for engineered channels that are stabilized with materials other than concrete, such as riprap, turf reinforcement mat, or vegetation to be identified in the WMAAs, an example study was prepared for an existing engineered channel stabilized with vegetation. The study demonstrates that a channel stabilized with materials other than concrete can be stable or have minimal potential for erosion. In order to allow for other channels that are stabilized with materials other than concrete to be identified in each WMAA, criteria for defining what is "stable" or "minimal potential for erosion" was determined.

Forrester Creek in the City of Santee was selected for the sample channel analysis. Forrester Creek is stabilized with vegetation from its confluence with the San Diego River downstream to Prospect Avenue upstream. For the purpose of this discussion, the confluence is the location where the floodplain of Forrester Creek meets the San Diego River floodplain, just west of

Gorge Avenue and Willowgrove Avenue, at the eastern side of the Carlton Oaks Golf Course. Stabilization occurred in two separate projects. The reach from the San Diego River confluence downstream to Mission Gorge Road upstream was constructed in 1990. The reach from Mission Gorge Road downstream to Prospect Avenue upstream is known as the Forrester Creek Improvement Project and was constructed in 2006-2007. Forrester Creek includes energy dissipators stabilized with riprap, concrete, and articulated concrete block at Mission Gorge Road undercrossing and Prospect Avenue undercrossing. Other than at bridge crossings, the engineered un-lined reach of Forrester Creek is stabilized with native vegetation. There is dense growth of trees in the channel.

Vegetation in Forrester Creek Downstream of Mission Gorge Road

Vegetation in Forrester Creek Upstream of Mission Gorge Road between Mission Gorge Road and State Route 52

Vegetation in Forrester Creek between State Route 52 and Olive Lane

Upstream of Prospect Avenue, Forrester Creek is a concrete-lined channel serving an urban area that is almost fully built out and served by existing underground storm drain systems and concrete-lined channels. Because of the vegetated reaches of Forrester Creek extending to the San Diego River, the concrete-lined portion of Forrester Creek and tributary underground storm drain systems and concrete-lined channels are not exempt from hydromodification management requirements unless the vegetated reaches of Forrester Creek are identified in the optional WMAA incorporated into the WQIP.

An erosion potential analysis was prepared for the vegetated reaches of Forrester Creek. An erosion potential analysis compares cumulative excess shear stress over all flows capable of transporting the channel-bed material from post-development to pre-development condition. The analysis used the same methods for determining erosion potential as presented in Section 4.1.1 and Attachment B.1.1 for the major river reaches.

For the purpose of determining flow rates and durations (hydrologic analysis), a regional scaling procedure developed by Hawley & Bledsoe in 2011 was used, the same method as presented in Section 4.1.1 and Attachment B.1.1 for the major river reaches. The method uses Duration Density Functions (DDFs) presented in the 2011 paper, "How do flow peaks and durations change in suburbanizing semi-arid watersheds? A southern California case study," to estimate cumulative durations for geomorphically-effective flows in a logarithmically-binned histogram format. Using these flows, long-term sediment transport can be subsequently estimated. The

analysis requires the following data, summarized below.

Summary of Input Data for Hydrologic Calculations for Forrester Creek Erosion Potential Analysis

Data	Units	Forrester Creek Watershed Existing Condition	Forrester Creek Watershed Future Condition
Tributary Area, A	square miles (mi^2)	23.36	23.36
Mean Annual Precipitation, MAP	inches	14	14
Length of Daily Flow Record	Years	30	30
Minimum Flow Rate	cubic feet per second	0.01	0.01
Number of Flow Bins	--	25	25
Impervious Cover	mi^2/ mi^2	0.4634	0.4792

Impervious cover for the Forrester Creek watershed was determined by assigning land-use specific imperviousness values to the land use categories presented in the SanGIS land use data sets (existing land use in 2012 and planned land use, described in Chapter 2.3). The composite imperviousness of the watershed was then calculated based on the existing condition and future condition land use distribution within the watershed. The Forrester Creek watershed is nearly fully built out therefore there is little change in imperviousness from existing to future condition. Impervious area calculations for the Forrester Creek watershed are provided in Attachment B.1.2.

For the purpose of determining shear stress in the channel (hydraulic analysis), normal depth calculations for the binned flow rates determined from the DDF analysis were prepared for two channel cross sections. One cross section was taken in the reach constructed in 1990, and one cross section in the Forrester Creek Improvement Project reach. For each reach, the cross section expected to experience the greatest shear stress was selected, based on channel width and slope. The analysis requires the following data, summarized below.

Summary of Input Data for Hydraulic Calculations for Forrester Creek Erosion Potential Analysis

Data	Units	Forrester Creek Watershed Cross Section 1300	Forrester Creek Watershed Cross Section 2475
Channel Bottom Width, b	feet	84	155
Channel Side Slopes, z1 and z2	Horizontal:Vertical	z1 = 1.5:1 z2 = 2:1	z1 = z2 = 2:1
Channel Slope	foot/foot	0.006	0.003
Channel Roughness (Manning's n)	--	0.100	0.100
Critical Shear Stress	pounds per square foot (lb/ft^2)	2.1	2.1

Critical shear stress for the reaches was estimated to be greater than or equal to 2.1 pounds per square foot (lb/ft2), based on review of permissible shear stress values presented in "Stability Thresholds for Stream Restoration Materials" (Fischenich 2001) and "Streambank Soil Bioengineering Considerations for Semi-Arid Climates" (Hoag and Fripp 2005). Based on Fischenich 2001, permissible shear stress for "live willow stakes" is approximately 2.10 to 3.10 lb/ft2.

The analysis results, presented in Attachment B.1.2, show that for both the existing and future condition, the shear stress for all geomorphically-effective flows based on the DDF analysis is less than the estimated critical shear stress of 2.1 lb/ft2. This means that no excess shear stress or "work" occurs in the channel in either the existing or future condition. Therefore, there is no increase in the duration of "work" (cumulative work), in the future condition, and erosion potential is 1.0.

Note that while the flow rates are the same in both the existing and future condition analyses, the duration of each flow rate is increased in the future condition. The flow rates in the flow bins are based on the watershed area, mean annual precipitation, and length of the synthetic record. These do not change from existing to future condition. The duration for each flow bin is related to the watershed area, mean annual precipitation, length of the synthetic record, and the impervious area. The duration increases in the future condition based on the increased impervious area. The increase in duration would result in increased cumulative work in the future condition if any of the flow rates resulted in shear stress greater than the estimated critical shear stress (excess shear stress, or "work"), because cumulative work is the product of work times duration.

The scenario that occurred in the Forrester Creek analysis, in which no work occurred in the expected range of geomorphically-effective flow rates, is a potential scenario for engineered channels because engineered conveyance systems are typically engineered for flood flows much greater and less frequent than the geomorphically-effective flows. For example, Forrester Creek is engineered to convey a 100-year single-storm event flow rate of approximately 12,450 to 13,840 cubic feet per second (cfs) within the channel. ForresterThe maximum geomorphically-effective flow rate for Forrester Creek based on the DDF analysis is 836 cfs.

4.1.2.4. Recommendation

Based on the study that was prepared for this Regional WMAA, the vegetated reaches of Forrester Creek from its confluence with the San Diego River downstream to Prospect Avenue upstream are recommended to be exempt from hydromodification management requirements. The analysis has shown that future increases in impervious area within the watershed are not expected to increase the erosion potential in Forrester Creek. The concrete-lined portion of Forrester Creek and existing storm drain systems draining directly to the concrete-lined portion of Forrester Creek should also be exempt. Storm drain systems draining directly to the vegetated reaches of Forrester Creek would also be exempt if there is no evidence of localized erosion issues at the storm drain outfall.

Because engineered conveyance systems are typically engineered to convey flood flows much greater than the geomorphically-effective flows, some engineered conveyance systems may be capable of conveying all geomorphically-effective flows at very low depths with shear stress less than critical shear stress, as was the case for Forrester Creek. Based on this, other engineered conveyance systems that are stabilized with materials other than concrete, such as riprap, turf reinforcement mat, or vegetation, including rehabilitated stream systems, and/or existing natural

stream systems that appear stable based on visual inspection may be studied using the exemption methodology presented in Attachment E. Systems evaluated using this methodology and that meet the criteria presented below, may be recommended as exempt systems in the optional WMAA incorporated into the WQIP. However, any future proposed HMP exemptions would need to be approved through the WQIP Update process (Regional MS4 Permit Section F.2.c.).

The following are additional requirements and criteria for the qualifying for potential exemption:

- To qualify for exemption, the studied conveyance system must discharge to an exempt system (i.e., an exempt water body, an exempt river reach, or an existing storm drain system or concrete-lined channel that extends all the way to an exempt water body or exempt river reach). In other words, the studied conveyance system cannot discharge to a non-exempt channel segment prior to discharge to the exempt system.
- The river reach exemptions were established based on assumptions that certain stabilized conveyance systems were exempt and associated tributary developments were exempt from hydromodification management flow control requirements. Therefore if a conveyance system that is being studied for exemption is tributary to an exempt river reach, exemption of the studied conveyance system is only feasible if the conveyance system was included in the analysis of the exempt river reach (see Attachment B.1.1), or pending submittal of an updated analysis for the exempt river reach to include the additional stabilized conveyance system.
- Channel cross section(s) must be selected to represent the condition where the greatest shear stress is expected in the channel(s).

4.1.3. Highly Impervious/Highly Urbanized Watersheds and Urban Infill

4.1.3.1. History

The March 2011 Final HMP, approved by the SDRWQCB under the 2007 MS4 Permit, provided a potential exemption from hydromodification management requirements for projects discharging runoff to a highly urbanized watershed (defined as an existing, pre-project impervious percentage greater than 70 percent) (herein "highly impervious / highly urbanized watersheds exemption") and another potential exemption for urban infill projects discharging runoff to an existing hardened or rehabilitated conveyance system, where the existing impervious area percentage in the watershed exceeds 40 percent (herein "urban infill exemption").

To qualify for the highly impervious / highly urbanized watersheds exemption, watershed impervious area calculations must be measured between the project site discharge location and the connection to a downstream exempt system. If a tributary area connects with the main line drainage path between the project site and the exempt system, then the entire watershed area contributing to the tributary shall be included in the calculation.

To apply the urban infill exemption for a project, the domain of analysis must be determined and the existing hardened or rehabilitated conveyance system must extend beyond the downstream terminus of the domain of analysis. The hardened or rehabilitated conveyance system must discharge to a receiving channel with a Low potential for channel susceptibility for this exemption to be granted (channel susceptibility determined using SCCWRP tool). Additionally, the exemption could only be granted if the potential future development impacts in the watershed would increase the watershed's impervious area percentage by less than 3 percent (as compared to the existing condition in the year 2010). If the potential future cumulative impacts in the watershed could increase the impervious area percentage by more than 3 percent (as compared to existing condition), then no exemption could be granted based on this item. Watershed impervious area calculations for this potential exemption must be measured upstream from the outfall of the urban conveyance system (to a non-concrete, non-riprap-lined or non-engineered channel) to the contributing watershed boundary (the entire watershed contributing to the discharge outfall).

4.1.3.2. Status under 2013 Regional MS4 Permit

Under the Regional MS4 Permit, highly impervious / highly urbanized watersheds and urban infill areas would fall under the category of areas identified by Copermittees as appropriate for an exemption. These areas may be identified in the optional WMAA incorporated into the WQIP.

4.1.3.3. Research and Results

The highly impervious / highly urbanized watersheds exemption was based on 2007 MS4 Permit language that exempted "construction of projects where the sub-watersheds below the projects' discharge points are highly impervious (e.g., >70%) and the potential for single-project and/or cumulative impacts is minimal." No modeling was prepared in support of this exemption during development of the March 2011 Final HMP – the exemption was provided by the 2007 MS4 Permit.

The urban infill exemption was based on a sensitivity analysis presented in Appendix F of the March 2011 Final HMP. The analysis was prepared using continuous simulation modeling of synthetic unit watersheds. The level of imperviousness was progressively increased for each synthetic unit watershed to simulate infill development. The flow duration statistics were examined to determine at what level of increased development the statistics became noticeably altered. Based on the study it was determined that urban infill projects have a relatively minor effect on the overall watershed's flow duration curve if the future cumulative additional impacts have the potential to increase the existing watershed impervious area by less than 3 percent. "Relatively minor effect" was not defined with a numeric threshold in Appendix F of the March 2011 Final HMP.

The sensitivity analysis prepared for the urban infill exemption examined synthetic unit watersheds with 40, 50, and 60 percent imperviousness. The extent of the spread in the results of the 40, 50, and 60-percent models demonstrated that unchecked development within urbanized watershed would have a noticeable effect on the peak flows and flow durations observed within the receiving waters. While watersheds 70% impervious and above were not modeled, unchecked development within these "highly impervious / highly urbanized watersheds" may also have a noticeable effect on the peak flows and flow durations observed within the receiving waters.

Since the adoption of the March 2011 Final HMP, a study titled, "Channel Enlargement in Semiarid Suburbanizing Watersheds: A Southern California Case Study," prepared by R.J. Hawley and B.P. Bledsoe, was published in Journal of Hydrology 496 (2013). The study presented a numeric threshold at which channel enlargement could be expected. In the study, "the threshold corresponding to the presence/absence of headcutting varied based on substrate type, and was roughly quantified as a sediment-transport ratio greater than ~1.20 in systems with a median grain size > 16 mm, and Lr ~1.05 when d50 < 16 mm." Sediment-transport ratio or Lr is the ratio of the cumulative excess shear stress over all flows capable of transporting the channel-bed material from post-development to pre-development condition. This is also known as "effective work index" or "erosion potential."

Using thresholds of 1.20 for systems with a median grain size > 16 mm, and 1.05 for systems with a median grain size < 16 mm, Geosyntec Consultants prepared a study in support of the Ventura County Hydromodification Control Plan (Ventura County HCP) to evaluate thresholds for additional impervious cover, from existing conditions (at the time of the HCP effective date) to build-out conditions, for the area tributary to a susceptible receiving water below which the risk of hydromodification impacts is considered negligible for that channel. The study is titled, "Basis for Designating Negligible Risk Based on Cumulative Future Buildout," and is presented in Appendix D of the Ventura County HCP (Final Draft dated September 2013). A copy of Appendix D of the Ventura County HCP (Final Draft dated September 2013) is provided in Attachment B.1.3. The following are the results of the study, presented as a function of a susceptible channel's tributary area (A) and median grain size (D50):

- If A > 1 square mile and D50 < 16 mm, then the threshold of additional imperviousness is evaluated using a nomograph that is based on empirical flow duration equations (Hawley and Bledsoe, 2011), empirical channel geometry relationships (Coleman et al, 2005 and County of San Diego, 2009), and Erosion Potential analyses. The results range

from 0.46% to 1.00% additional imperviousness, depending on watershed size and mean annual precipitation (MAP).

- If A < 1 square mile and D50 < 16 mm, then the threshold of additional imperviousness is 0.44%.
- If D50 > 16 mm, then the threshold of additional imperviousness is 1.65%.

The thresholds of additional imperviousness presented in the Ventura County HCP (ranging from 0.44% to 1.65%) are lower than the 3% allowable limit presented in the San Diego County Final HMP dated March 2011.

4.1.3.4. Recommendation

Based on evaluation of the exemptions presented in the March 2011 Final HMP and comparison with more recent research prepared for the Ventura County HCP, resurrection of the highly impervious / highly urbanized and urban infill exemptions from the March 2011 Final HMP is not recommended. The research prepared in support of the Ventura County HCP determined lower thresholds of additional impervious area (ranging from 0.44% to 1.65%) than the limit presented in the San Diego County Final HMP dated March 2011 (3%).

4.1.4. Tidally Influenced Lagoons

4.1.4.1. History

The March 2011 Final HMP, approved by the SDRWQCB under the 2007 MS4 Permit, provided a potential exemption from hydromodification management requirements for projects discharging runoff directly to a tidally-influenced lagoon. To qualify for the potential exemption, additional analysis would be required to assess the effects of the freshwater / saltwater balance and the resultant effects on lagoon-system biology. This assessment, which would be required by other permitting processes such as the Army Corps of Engineers, California Department of Fish and Game, etc., must be provided by a certified biologist or other specialist as approved by the governing municipality. Additionally, project discharges must include an energy dissipation system (riprap, etc.) designed to mitigate 100-year outlet velocities based upon a free outfall condition.

4.1.4.2. Status under 2013 Regional MS4 Permit

The Regional MS4 Permit language discussing exemptions from hydromodification management does not specifically include the terminology that was used in the Final HMP including, "tidally influenced lagoons" or "tidally influenced areas." The Permit does indicate that exemptions from hydromodification management may be granted for discharges from existing underground storm drains and concrete lined conveyance channels to “enclosed embayments” (lagoons). However, other drainage systems not meeting the above definition may be identified by Copermittees as appropriate for an exemption in the optional WMAA incorporated into the WQIP.

4.1.4.3. Recommendation

Engineered conveyance systems discharging to lagoons that are stabilized with materials other than concrete, such as riprap, turf reinforcement mat, or vegetation, including rehabilitated stream systems, and/or existing natural stream systems that appear stable based on visual inspection may be studied using the exemption methodology presented in Attachment E. Systems evaluated using this methodology and that meet the criteria presented below, may be recommended as exempt systems in the optional WMAA incorporated into the WQIP. However, any future proposed HMP exemptions would need to be approved through the WQIP Update process (Regional MS4 Permit Section F.2.c.).

The following are additional requirements and criteria for the qualifying for potential exemption:

- To qualify for exemption, the studied conveyance system must discharge to an exempt system (i.e., an exempt water body, an exempt river reach, or an existing storm drain system or concrete-lined channel that extends all the way to an exempt water body or exempt river reach). In other words, the studied conveyance system cannot discharge to a non-exempt channel segment prior to discharge to the exempt system.
- Channel cross section(s) must be selected to represent the condition where the greatest shear stress is expected in the channel(s)

5. Conclusions

5.1. Watershed Management Area Characterization

The WMA Characterization data was developed using available regional data to further understand the macro-scale watershed characteristics and processes in the San Diego permit region. The Regional MS4 Permit allows for flexibility in complying with land development requirements when using the information developed in the WMAA to improve water quality planning and implementation associated with land development. This dataset will assist with identifying the opportunities and constraints for projects and management decisions based on a watershed-scale (rather than piecemeal project identification without context within the watershed) and provides Copermittees the ability to exercise the option to create an alternative compliance program that offers the opportunity to develop watershed-specific alternatives to universal onsite structural BMP implementation. The characterization data includes:

Characterization Data	Utilization Potential
Dominant Hydrologic Process: • Overland flow • Infiltration • Interflow	• Identify areas for enhanced infiltration or collection of storm water for treatment • Implement management measures that correspond to pre-development conditions – promotes long-term channel stability and health • Increases understanding of the natural functioning of the watershed and what has been (or is at risk of being) altered by urbanization.
Stream Characterization: • Reach type • Bed material • Bank material • Hydrographic category • Channel infrastructure	• Preliminary dataset that can be used to conduct stream power evaluations • Identify channel systems for preservation or restoration • Identification of appropriate space for channel processes to occur (e.g., flood plain connectivity) • Insight to sensitivity of receiving stream reach • Indicates the features within channels that affect water and sediment movement through the watershed

Characterization Data	Utilization Potential
Land Use: • Existing • Future	• Foresight (identifies relative risks, opportunities, or constraints) in comparing future to existing land uses, i.e., areas that may be more/less vulnerable to adverse impacts to changes in storm water runoff associated with development • Encourage infill development
Potential Critical Coarse Sediment Yield Areas	• Preservation of areas or function that contributes critical sediment within the watershed to stream armoring/stability • Assist with identifying potentially susceptible stream reaches that require uninterrupted coarse sediment supplies to remain stable • Dual goal of open space conservation

Regarding the identification of the potential critical coarse sediment yield areas in the Regional WMAA using readily available regional datasets, it is anticipated that when more precise estimates for potential critical coarse sediment yield areas are required for a particular site or subarea that this regional study will be augmented with site-specific analysis. Development projects must avoid critical sediment yield areas or implement measures that allow critical coarse sediment to be discharged to receiving waters, such that there is no net impact to the receiving water to meet the requirements of the Regional MS4 permit. As such, projects should consult the Model BMP Design Manual and/or jurisdiction specific BMP Design manual for options to meet the Regional MS4 permit requirements. It is anticipated that the data will not be static but will be enhanced over time through future studies or field assessments that will refine what is currently a macro-level data set.

5.2. Template for Candidate Project List

It is anticipated the Copermittees that elect to develop alternative compliance programs will conduct a separate exercise to nominate potential candidate projects for inclusion into the WQIPs using the template developed for this project.

5.3. Hydromodification Management Exemptions

Attachment B.2 presents hydromodification management applicability/exemption mapping. The mapping includes receiving waters that are exempt based on the Regional MS4 Permit or recommended exempt based on studies.

Receiving waters that are **exempt** based on the Regional MS4 Permit include:

- The Pacific Ocean
- San Diego Bay
- Mission Bay
- Lakes and Reservoirs
- Existing underground storm drains or concrete-lined channels draining directly to bays or the ocean

Receiving waters or conveyance systems that are recommended exempt based on studies that were prepared as part of the Regional WMAA or prepared by others and provided for this purpose include:

- Otay River from Outfall at San Diego Bay to Interstate 805
- San Diego River from Pacific Ocean to confluence with San Vicente Creek
- San Dieguito River from upstream edge of the railroad crossing to Lake Hodges Dam
- San Luis Rey River from Pacific Ocean to upstream river limit of Basin Plan subwatershed 903.1 upstream of Bonsall and near Interstate 15
- Sweetwater River from San Diego Bay to Sweetwater Reservoir Dam
- Forrester Creek stabilized reach from the confluence with the San Diego River to Prospect Avenue

ATTACHMENT A.4
POTENTIAL COARSE SEDIMENT YIELD AREAS

A.4.1 Geology Grouping

Geologic grouping was based on the mapped geologic unit as determined by published geologic mapping information. The following describes the methodology utilized to determine bedrock or sedimentary characteristics, anticipated grain size, and suitability for infiltration. A complete list of the various geologic maps used in this evaluation is listed in Chapter 6.

Due to the various mapped scales of the published data and differing mapped unit names, the geologic units were initially compiled into similar categories where possible. For example, the Lindavista Formation is mapped as unit Ql on geologic maps at a scale of 1:24,000 but correlates to the same unit Qvop8 on geologic maps at a scale of 1:100,000. Following the compilation of geologic unit names, the units were differentiated between crystalline bedrock and sedimentary formations based on geologic characterization and material behavior. The Point Loma Formation for example, is a Cretaceous-age sandstone, but it was classified as a "coarse bedrock" unit due to its indurated and resistant nature.

For each site location, the predominant geologic units were then described as "coarse" or "fine" based on typical weathering characteristics of the bedrock units, or primary grain size of the sedimentary units. For example, granodiorite or tonalite crystalline rock typically weathers to a coarse material such as a silty sand and therefore was classified as "coarse," compared to a gabbro which generally weathers to a sandy clay and was characterized as "fine." Sedimentary formations can be more variable, such as the Mission Valley Formation. In this case, the Mission Valley Formation was characterized as "coarse" since the unit is predominantly comprised of sandstone even if it does contain localities of siltstone and claystone within the unit.

To further characterize the sedimentary formations, these units were evaluated for suitability of infiltration. Since no field investigations were performed for this evaluation to determine permeability, the differentiation between impermeable and permeable were based on the age of the geologic unit with the assumption that relatively younger sedimentary units of Pleistocene-age or younger (<1.6 mya) would be more susceptible to surface water infiltration. Geology grouping of different map units is presented in Table A.4.1

A.4.2 Quantitative Analysis

Soil loss estimates for each Geomorphic Landscape Unit were estimated using the Revised Universal Soil Loss Equation (RUSLE; Renard et al. 1997) listed below:

$$A = R \times K \times LS \times C \times P$$

Where

A = estimated average soil loss in tons/acre/year

R = rainfall-runoff erosivity factor

K = soil erodibility factor

LS = slope length and steepness factor

C = cover-management factor

P = support practice factor; assumed 1 for this analysis

Regional datasets used to estimate the inputs required to estimate the soil loss from each GLU are listed in table below:

Dataset	Source	Download year	Description
RUSLE – R Factor	SWRCB	2014	Regional R factor map was downloaded from ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_R_Factor/
RUSLE – K Factor	SWRCB	2014	Regional K factor map was downloaded from ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_K_Factor/
RUSLE – LS Factor	SWRCB	2014	Regional LS factor map was downloaded from ftp://swrcb2a.waterboards.ca.gov/pub/swrcb/dwq/cgp/Risk/RUSLE/RUSLE_LS_Factor/
RUSLE – C Factor	USEPA	2014	Regional C factor map was downloaded from http://www.epa.gov/esd/land-sci/emap_west_browser/pages/wemap_mm_sl_rusle_c_qt.htm#mapnav

GIS analysis was used to calculate the area weighted estimate of R, K, LS and C factors using the regional datasets listed in the table above. For the developed land cover the C factor was then adjusted to 0 from the regional estimate to account for management actions implemented on developed sites (e.g. impervious surfaces). Soil loss estimates ranged from 0 to 15.2 tons/acre/year.

For evaluating the degree of relative risk to a stream solely arising from changes in sediment and/or water delivery SCCWRP Technical Report 605, 2010 states:

> *"The challenge in implementing this step is that presently we have insufficient basis to defensibly identify either low-risk or high-risk conditions using these metrics. For example, channels that are close to a threshold for geomorphic change may display significant morphological changes under nothing more than natural year-to-year variability in flow or sediment load.*

- *Acknowledging this caveat, we nonetheless anticipate that changes of less than 10% in either driver are unlikely to instigate, on their own, significant channel changes. This value is a conservative estimate of the year-to-year variability in either discharge or sediment flux that can be accommodated by a channel system in a state of dynamic equilibrium. It does not "guarantee," however, that channel change may not occur—either in response to yet modest alterations in water or sediment delivery, or because of other urbanization impacts (e.g., point discharge of runoff or the trapping of the upstream sediment flux; see Booth 1990) that are not represented with this analysis.*
- *In contrast, recognizing a condition of undisputed "high risk" must await broader collection of regionally relevant data. We note that >60% reductions in predicted sediment production have resulted in both minimal (McGonigle) and dramatic (Agua Hedionda) channel changes, indicating that "more data" may never provide absolute guidance. At present, we suggest using predicted watershed changes of 50% or more in either runoff (as indexed by change in impervious area) or sediment production as provisional criteria for requiring a more detailed evaluation of both the drivers and the resisting factors for channel change, regardless of other screening-level assessments. Clearly, however, only more experience with the application of such "thresholds," and the actual channel conditions that accompany them, will provide a defensible basis for setting numeric standards."*

The following criterion was developed using the suggestions listed above and then used to assign relative sediment production rating to each GLU:

- Low: Soil Loss < 5.6 tons/acre/year [GLUs that have a soil loss of 0 to 5.6 tons/acre/year produces around 10% of the total coarse sediment soil loss from the study area]
- Medium: 5.6 tons/acre/year < Soil Loss < 8.4 tons/acre/year
- High: > 8.4 tons/acre/year [GLUs that have a soil loss greater than 8.4 tons/acre/year produces around 42% of the total coarse sediment soil loss from the study area]

Results from the quantitative analysis are summarized in Table A.4.2.

Table A.4.2 Relative Sediment Production for different Geomorphic Landscape Units

Geomorphic Landscape Unit (GLU)	Area (acres)	K	LS	C	R	A	Relative Sediment Production	Critical Coarse Sediment
CB-Agricultural/Grass-1	52883	0.20	4.67	0.14	50	6.5	Medium	No

A4.3 Field Assessment

Site Selection:

Forty locations were selected from the study region for field assessment. Sites were selected such that they are accessible by existing road network based on review of satellite imagery and are uniformly distributed considering the following criteria:

- Geologic grouping
- Land cover
- Slope category
- WMA
- Jurisdiction

Yellow circles in the figure below shows the 40 locations for which field assessment was performed.

Pre-Field Activities

Prior to conducting field activities, the consultant team reviewed available published geologic information at each site location and prepared satellite imagery of each site using Google Earth™. Pre-field activities consisted of evaluating site access at each location using aerial imagery and logistics were coordinated based on regional site location to maximize field efficiency.

Site Reconnaissance

Site reconnaissance was performed at forty locations between 22 January and 7 February 2014 by a team of geologists. The reconnaissance consisted of:

- Visual soil classification,
- Assessing existing vegetative cover (0-100%),
- Qualitative assignment of existing sediment production (low, medium, and high) [based on existing vegetative cover],
- Qualitative assignment of potential sediment production (low, medium, and high)[assuming there is 0% vegetative cover], and
- Identifying existing erosional features.

Descriptions and visual classifications of the surficial materials were based on the Unified Soil Classification System (USCS). Underlying geologic units were confirmed where exposed formations were observed within the individual site limits.

SITE AND GEOLOGIC CONDTIONS

Our knowledge of the site conditions has been developed from a review of available geologic literature, previous geologic and geotechnical investigations by the consultant team in the study region, professional experience, site reconnaissance, and field investigations performed for this study.

Surface Conditions

Site locations were sited in open space with the exception of sites ID-27, -30, and -31 which were situated within developed areas with paved streets and sidewalks. The surface conditions at the site locations were characterized by sloping terrain varying from relatively flat (< 5%) to very steep slopes (> 40%). At the time of our reconnaissance the natural hillsides along the areas of interest were covered by varying degrees of moderate to dense growth scrub brush, low grasses, and scattered trees.

Existing erosional and geomorphic features at each site location were identified where possible. The observed erosional features included notable drainages, rilling, scour, and sediment accumulation. Observed geomorphic features included areas of minor slope instability and surficial slumping. Several sources of ground disturbance were identified during the site reconnaissance included active grading operations and bioturbation.

An evaluation of the existing and potential sediment production for each site was determined based on surface conditions. Sediment production was assigned as “high, medium, or low” based on the existing conditions and consultant team’s professional experience.

Surficial Deposits

Surficial deposits, including topsoil, alluvium, colluvium, slopewash, and residual soils are present in portions of the study area within the natural drainages and mantling the slope areas. The composition and grain size of these materials are variable depending on the age, parent sources, and mode of deposition.

Geologic Conditions

Our knowledge of the subsurface conditions at the site locations is based on a review of available published geologic information, professional experience, site reconnaissance, previous explorations and geotechnical investigations performed by the consultant team in the study region.

ATTACHMENT A.5
PHYSICAL STRUCTURES

A.5 Physical Structures

The desktop-level analysis to identify existing physical structures within the nine watershed management areas within the San Diego region utilized the following GIS data sources:

- ESRI ArcMap, Google Earth, and Google Maps products
- Federal Emergency Management Agency (FEMA) Flood Insurance Study (FIS) Flood Profiles and FEMA Flood Insurance Rate Map (FIRM)
- National Flood Hazard Layer (NFHL)
- Municipal master drainage plans (as provided)
- San Diego Geographic Information Source (SanGIS) Municipal Boundaries and Hydrologic Basins
- United States Geological Survey (USGS) National Hydrography Dataset (NHD) California data
- Stream data generated as indicated in Section 2.2

The following documents the process used to identify the physical structures along the reaches and the resulting GIS data:

- The process began by importing the data sources indicated above into a single ArcMap document that served as a master map file from which all further analysis proceeded.
- The data were screened and selected for inclusion as appropriate to the project scope.
- Point features were placed along river reach line segments to coincide with visually identified structures, utilizing different feature symbols according to the type of infrastructure.
- In the case of levees, the point was placed at the downstream-most end of the FEMA NFHL Shapefile. All point features generated in this task appear in the GIS shapefile.
- Municipal boundaries intersecting river reaches were identified to identify the applicable municipal drainage plan data.
- Point feature attributes and associated information for Physical Structures GIS shapefile is indicated in Table A.5.1 below.

Table A.5.1: Structure Identification Point Feature Attribute Development and Information

Attribute	Description
Struct_ID	The Structure ID field provides a six-digit identification number based upon the structure's specific location within a watershed. The first three digits in the code reflect the structure's Hydrologic Unit (HU) Basin number (ranging between 902-911 for Region 9, as defined in the Water Quality Control Plan for the San Diego Basin). The subsequent three digits reflect the structure's location along the reach, ascending along the channel from the headwaters to tailwaters (ranging between 001-999, beginning at the confluence and increasing in the upstream direction).

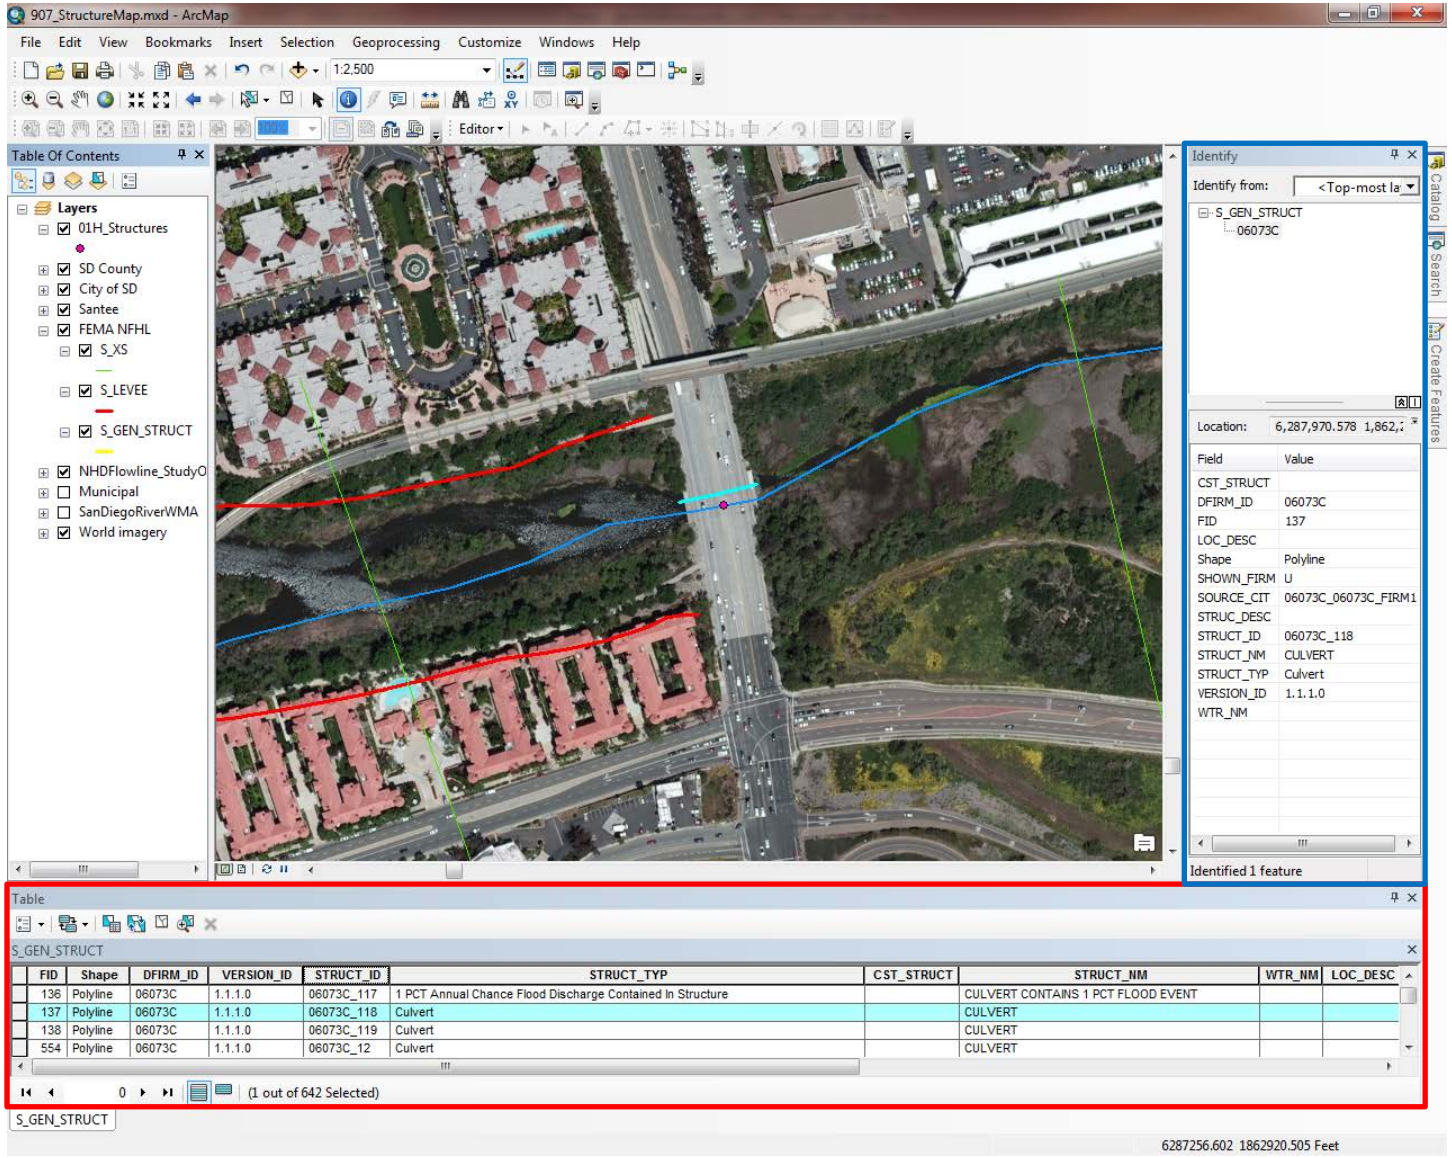
Attribute	Description
WMA	The Watershed Management Area field provides the name of the watershed in which the structure exists. The WMA corresponds with the HU identified in the first three digits in the Struct_ID (e.g., 911, Tijuana Watershed).
Channel_ID	The Channel ID field provides the name of the channel in which the structure exists.
Struct_Typ	The Structure Type field classifies known structures as one of the following types:, Bridge, Culvert, Dam, Energy Dissipater, Flood Management Basin, Flood Wall, Grade Control, Levee, Pipeline, Weir.
Struct_Dtl	The Structure Detail field provides known quantitative information for multi-section culverts.
Struct_Mtl	The Structure Material field provides known qualitative information for structure material composition.
Struct_Shp	The Structure Shape field provides known geometric information for culvert shapes, and is classified as one of the following types: Arch, Box, Pipe.
Jurisd_ID	The Jurisdiction ID field, when applicable, provides the known separate structure identification number developed and utilized by the jurisdiction or entity responsible for creating and distributing the coinciding structure Shapefile data used for this analysis. This number was copied from the coinciding external Shapefile data attribute field best representing a unique jurisdiction or entity-based identification number (external Shapefile data received from regional WMAA data call; for jurisdictional information, see "Other" attribute field). Coinciding external Shapefile data was used to determine various structure attributes.
Plan_ID	The Plan ID field, when applicable, provides the known structure plan number corresponding with the Jurisdiction ID. This number was copied from the coinciding external Shapefile data attribute field best representing a unique plan number received from the regional WMAA data call (external Shapefile data received from regional WMAA data call; for jurisdictional information, see "Other" field). Coinciding external Shapefile data was used to determine various structure attributes.
Diameter	The Diameter field, when applicable, provides the known diameter (in US feet) for culverts.
Length	The Length field, when applicable, provides the known length (in US feet) for select structure types. When lengths were determined using FEMA FIS Flood Profiles, the scaled horizontal distances along the indicated roadway or channel slope were used.
Width	The Width field, when applicable, provides the known width (in US feet) for select structure types.
Height	The Height field, when applicable, provides the known height (in US feet) for select structure types. When heights were determined using FEMA FIS Flood Profiles, the scaled vertical distances from channel bed to indicated roadway bottom were used.
US_Invert	The Upstream Invert field, when applicable, provides the known upstream invert elevation (in US feet) for select structure types.
DS_Invert	The Downstream Invert field, when applicable, provides the known downstream invert elevation (in US feet) for select structure types.

Attribute	Description
RD_EL_NAVD	The Roadway Elevation (NAVD) field, when applicable, provides the known roadway elevation (in US feet, NAVD) for select structure types. When roadway elevations were determined using FEMA FIS Flood Profiles, the horizontal projection onto the vertical grid scales were used.
Loc_Descr	The Location Description field, when applicable, provides information for structures crossing a known roadway. In nearly all cases, Google Earth imagery was used to determine the roadway name.
Other	The Other field is used to convey any information not present within the preceding fields. Typically, "other" information includes jurisdictional, plan, and supplemental dimensions for a given structure.

Example Structure Identification

The following example demonstrates the structure identification process for a discrete structure (ID 907029) along the San Diego River. The San Diego River is located in the San Diego River watershed (WMA 907). Scanning the river from lower to higher reached, a new point feature was placed at the road crossing over the San Diego River as indicated in Figure A.5.1. Select attributes of this particular structure were available from the FEMA NFHL as displayed in the highlighted boxes in Figure A.5.1. Additional attributes such as the culvert height, length, roadway elevation, and name were also determined from the FIS Flood Profile as indicated in Figure A.5.2. Satellite imagery (e.g., Google) was used to verify the existence of structure. In this case, the most current Google Map data indicated that the culvert still exists and that the roadway name has been changed to Qualcomm Way. When structures could not be verified with satellite imagery, the structure identification was based solely upon the information provided or readily available and was not physically verified in the field. Figure A.5.3 displays an example of imagery used to identify structures.

Figure A.5.1: Typical ArcMap Window



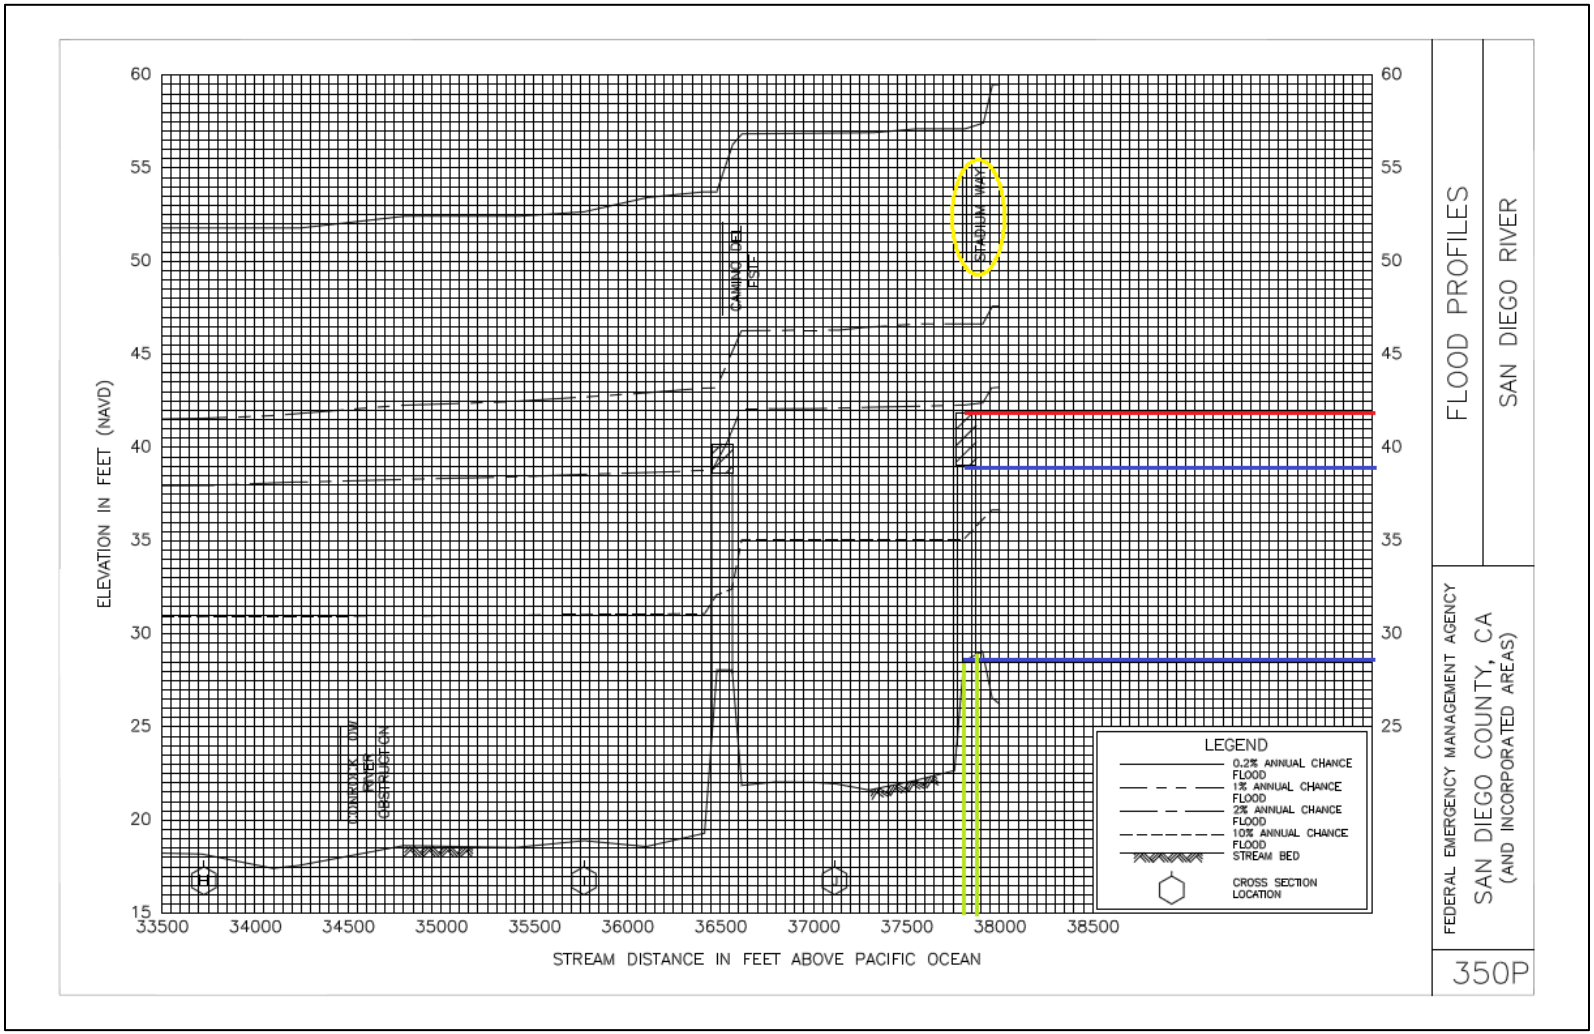


Figure A.5.2: Typical FEMA FIS Flood Profile

Legend: roadway elevation (red), roadway name (yellow), culvert height (blue), culvert width (green)

Figure A.5.3: Google Map Imagery for Structure Identification

The following bridge structure dimensional attributes were included in the point feature attributes:

- length 110 feet
- height 10 feet
- roadway elevation 41.9 feet

The attribute table associated with the identified structure included in the GIS shapefile is indicated in Table A.5.2.

ATTACHMENT B
HYDROMODIFICATION MANAGEMENT APPLICABILITY/EXEMPTIONS

ATTACHMENT B.1

ADDITIONAL ANALYSIS FOR HYDROMODIFICATION MANAGEMENT EXEMPTIONS

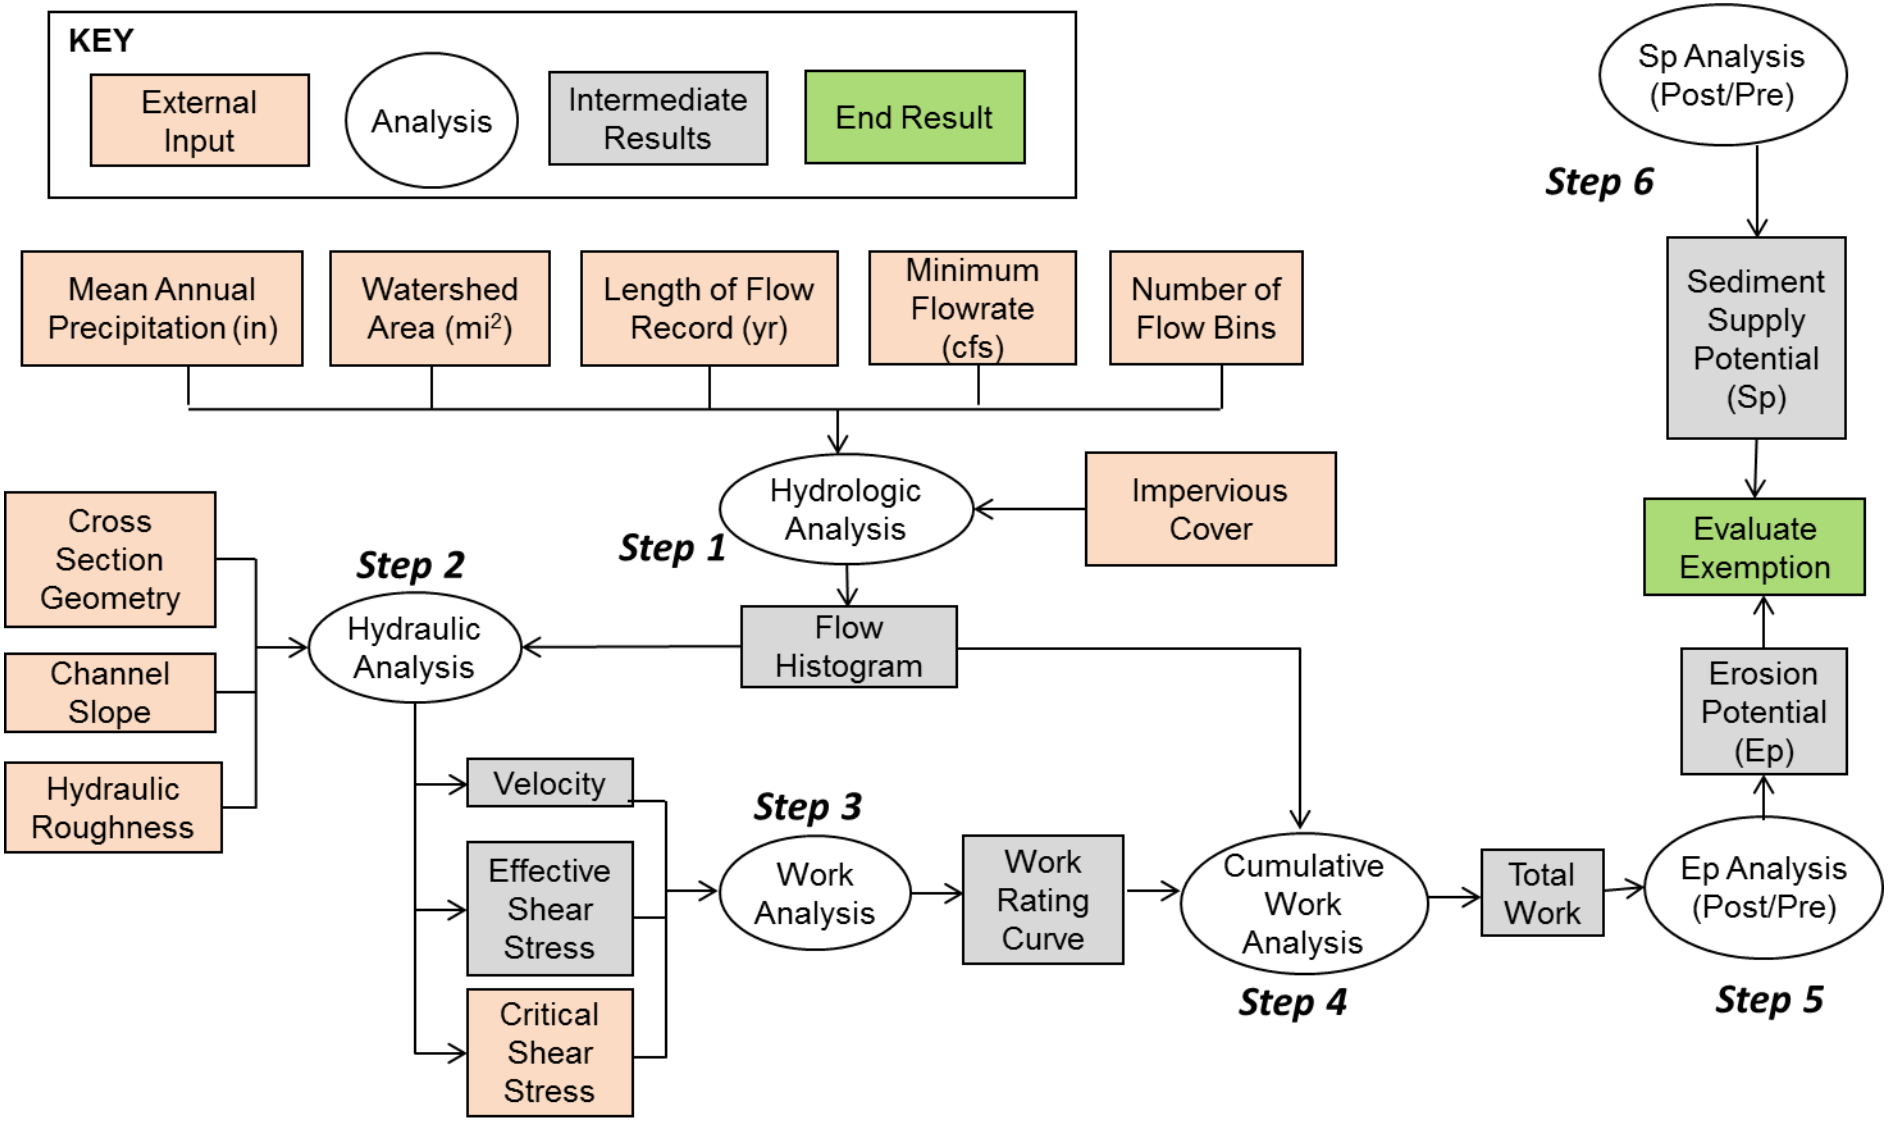
ATTACHMENT B.1.1
EXEMPT RIVER REACHES

B.1.1 Exempt River Reaches

B.1.1.1 Approach for Exempt River Reach Analysis

The approach selected in this cumulative hydromodification impacts study accounts for: (1) hydrology, (2) channel geometry, (3) bed and bank material, and (4) sediment supply. The selected approach compares long-term changes in sediment transport capacity, or in-stream work, and sediment supply for the existing and future development conditions. The ratio of future/existing condition transport capacity, or work, is termed Erosion Potential (Ep). The ratio of future/existing condition bed sediment supply is termed Sediment Supply Potential (Sp). To calculate Ep, the hydrology, channel geometry, and bed/bank materials are characterized for the existing and future conditions. To calculate Sp, the sediment supply factor is characterized for the existing and future conditions.

The findings in this study propose exemption for a given river reach if the analysis satisfies the following criteria:



- Ep < 1.05 when d50 < 16 mm or Ep < 1.20 when d50 > 16 mm, and;
- Sp > 0.90

The following bullet points provide basis for the criteria listed above:

- For Ep
    - According to the Journal of Hydrology article titled Channel Enlargement in Semiarid Suburbanizing Watersheds: A Southern California Case Study (Hawley and Bledsoe, 2013): "*The threshold corresponding to the presence/absence of headcutting varied based on substrate type, and was roughly quantified as a sediment-transport ratio greater than ~1.20 in systems with a median grain size > 16mm, and [Ep] ~ 1.05 when* $d_{50} < 16$ *mm"*
- For Sp
    - Soar and Thorne (2001) indicate that a greater than 10% reduction in sediment supply can have potentially significant effects on stream stability.
    - SCCWRP Technical Report 605, 2010 states that changes of less than 10% in either driver (Water delivery and sediment are the drivers in this report) are unlikely to instigate, on their own, significant channel changes.

The flow chart summarizing the analysis procedure is presented below.

Flowchart for Exempt River Reach Analysis

B.1.1.2 Selection of Inputs for Exempt River Reach Analysis

The following steps were implemented for each river reach:

- Step 1 – Hydrologic Analysis:
  - Due to limited flow data, a flow duration equation developed for Southern California (Hawley and Bledsoe, 2011) was used to estimate existing and future flow histograms for each watershed.
  - The change in impervious cover between existing and future development conditions was estimated using the developable land use layer from Section 2.3.
  - A desktop-level GIS exercise was performed to manually assign land use classifications if the parcel in the developable land use layer directly discharges into the analyzed reach. Results are summarized in Section B.1.13.
  - Assumptions for percent imperviousness for each land use type were based on the information provided in the San Diego County Imperviousness Study (County of San Diego, 2010).
  - The table below presents the input parameters used to construct flow histograms, as well as the estimated channel slope at the critical cross section.

Exempt River Reach	Area (sq. miles)	Mean Annual Precipitation (in)	Length of Daily Flow Record (Years)	Channel Slope (ft/ft)
San Diego River	173	14.5	30	0.0012
Otay River – West of Interstate 805	46	12	30	0.0026
San Dieguito River	45	14	30	0.0012
San Luis Rey River	353	20	30	0.0019
Sweetwater River	72	12	30	0.0033

- Step 2 – Hydraulic Analysis: The reach type classification from Section 2.2 was used to identify the critical cross section along the reach for Ep analysis. A critical flow rate of $0.5Q_2$ was assigned to estimate the critical shear stress for the analyzed cross section. Flow rates below $0.5Q_2$ were assumed to perform no work on the reach.
- Step 3 – Work Analysis: The simplified effective work equation shown below is used to calculate the work done for each flow bin.

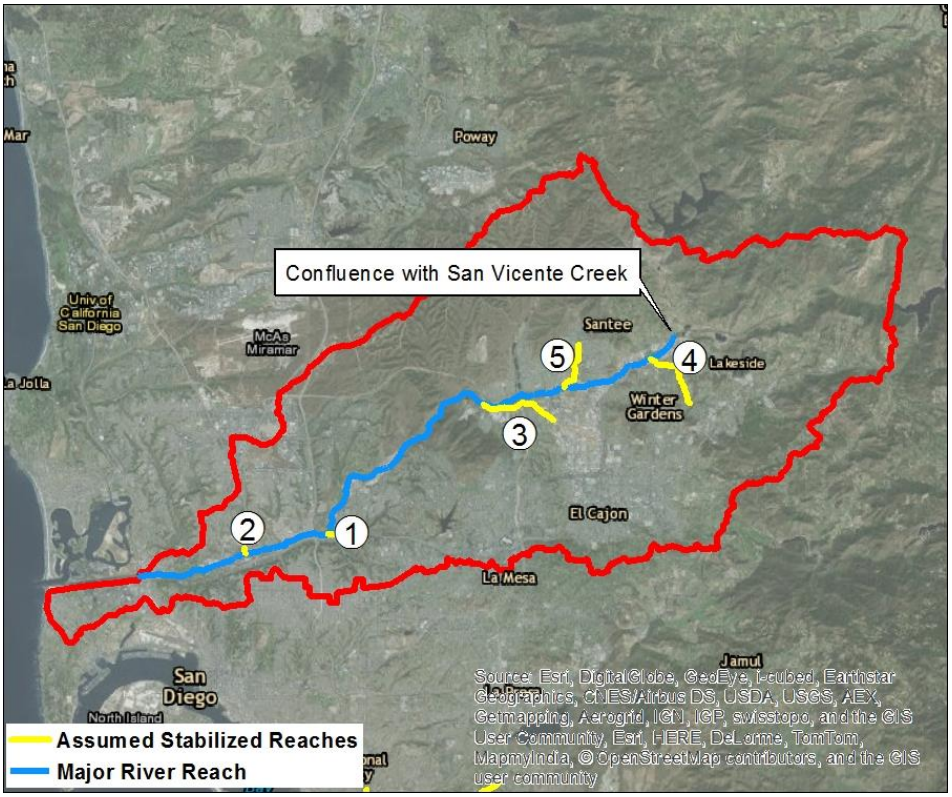
$$W = (\tau - \tau_c)^{1.5} V$$

Where

W = Work (dimensionless)
τ = effective Shear Stress [lb/ft^2]
τ_c = Critical Shear Stress [lb/ft^2]
V = Flow Velocity [ft/s]

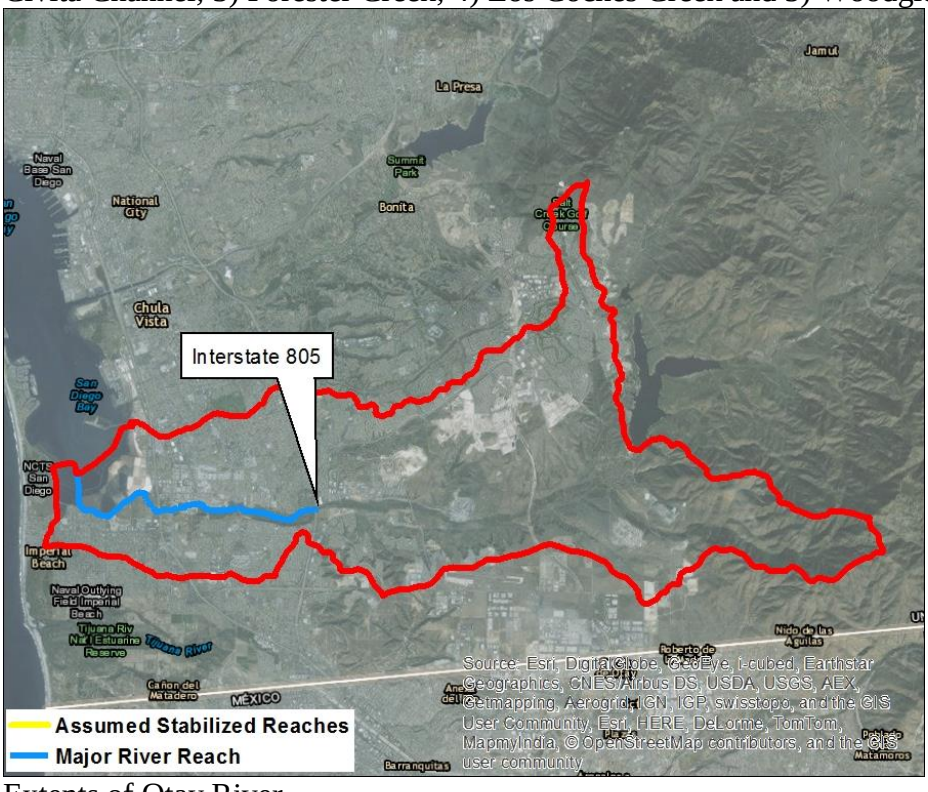
- Step 4 – Cumulative Work Analysis: Cumulative work is a measure of the long-term total work or sediment transport capacity performed at a given stream location. Cumulative work incorporates both discharge magnitude and flow duration distributions for the full range of simulated flow rates. Cumulative work is calculated by multiplying work and

duration for each bin. Total work is calculated through summation of work from all flow bins.



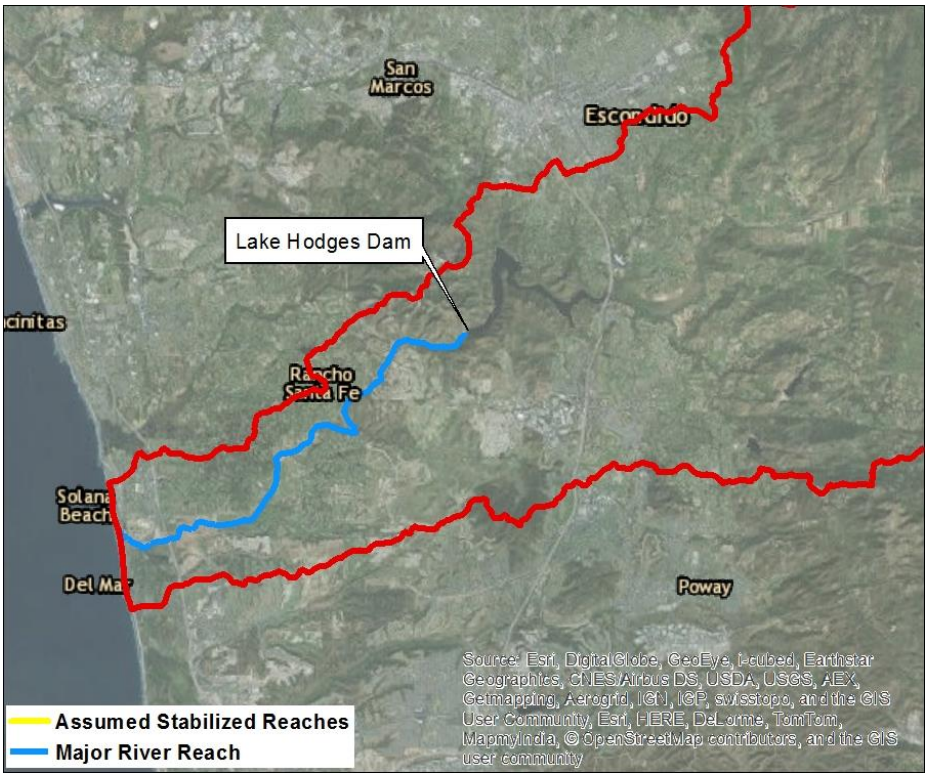
- Step 5 – Ep Analysis: Ep is calculated by dividing the total work of the future condition by that of the existing condition. The existing river reaches analyzed appear relatively stable and have not experienced excessive geomorphic instability due to the alteration of the drainage areas. Given the stable condition of the existing channels, the existing condition was used as the baseline condition instead of natural. Results from the Ep analysis are presented in Section B.1.1.3.
- Step 6 – Sp Analysis: Coarse Sediment Supply Potential for each watershed was estimated using the quantitative results from Section 2.4. First, the watershed coarse sediment soil loss was estimated for all GLUs producing coarse sediment. Then, the future-condition coarse sediment soil loss was estimated by subtracting the approximate exempt parcel soil loss from the existing soil loss. Sp is ultimately calculated by dividing the future coarse sediment soil loss by the existing coarse sediment soil loss. Results from Sp analysis are presented in Section B.1.1.3.

Steps 1 to 5 were performed in Excel and Steps 1 and 6 were executed in GIS. Ep estimates for the exempt river reaches are included in this attachment.

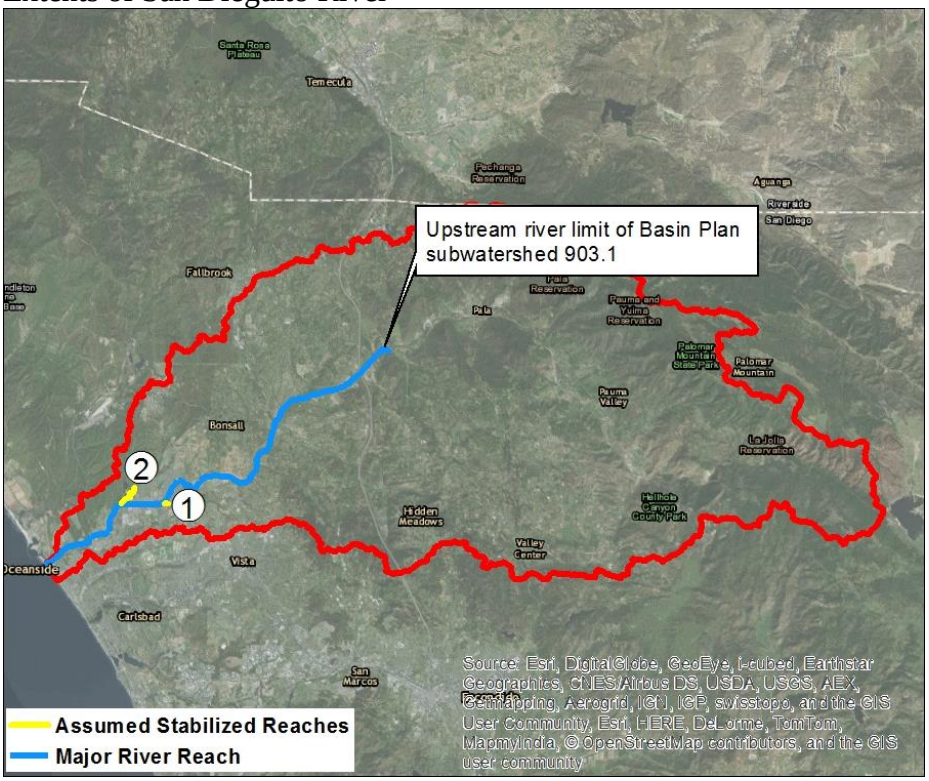


Exempt river reach extents are shown in the figures below. Figures also indicate the tributaries assumed to be stable for performing the erosion potential analysis as a conservative approach to approximate potential HMP exempt flows that may enter the river reach being analyzed.

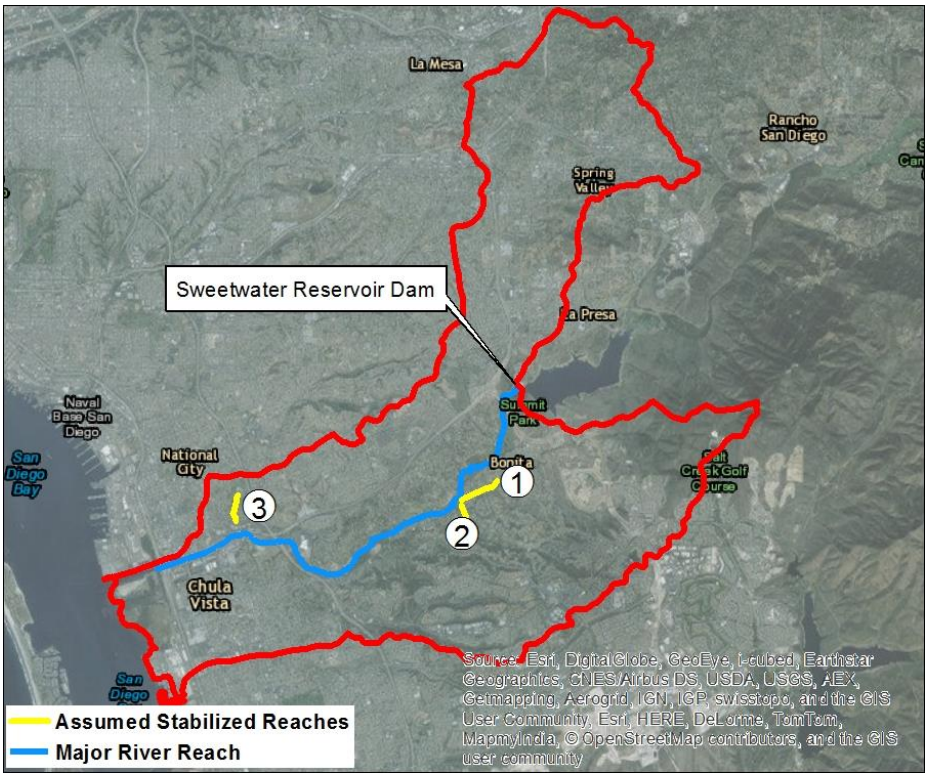
For a PDP draining to one of the assumed stable tributaries shown in the following exempt reach figures, the PDP applicant shall verify and document that the assumed stable tributary is a stabilized conveyance system by using the methodology presented in section 4.1.2 prior to claiming exemption from hydromodification management requirements.



For a PDP draining to a tributary not shown in the figures below to be considered for exemption, a stability analysis using the section 4.1.2 methodology is to be conducted for the given tributary. If the stability analysis determines the tributary is stable, then the exempt river reach analysis indicated in section 4.1.1 shall be performed by adding the additional stabilized tributary to the current list of tributaries shown in the figures below to confirm that the reach satisfies the Ep and Sp criteria.



Extents of San Diego River and extents of assumed Stabilized Reaches: 1) Alvarado Creek; 2) Civita Channel; 3) Forester Creek; 4) Los Coches Creek and 5) Woodglen Vista Creek



Extents of Otay River

Extents of San Dieguito River

Extents of San Luis Rey River and extents of assumed Stabilized Reaches: 1) Frazee Road Channel and 2) Pilgrim Creek

Extents of Sweetwater River and extents of assumed Stabilized Reaches: 1) Sunnyside Channel; 2) Long Canyon Channel; and 3) National City Gold Course Channel

The table below presents the summary of the developable land in each of the five watersheds with the exempt river reach and the estimated developable area that will be exempted from hydromodification management area requirements if the exempt river reach exemption is reinstated. This area will still be subject to the pollutant control requirements from the regional MS4 permit.

Exempt River Reach	Developable Land		
	Total (acres)	Area exempt (acres)	Exempt (%)
Otay River – West of Interstate 805	4,310	68	2%
San Diego River	13,667	1,196	9%
San Dieguito River	4,653	1,054	23%
San Luis Rey River	77,418	4,223	5%
Sweetwater River	1,332	255	19%

B.1.1.3 Results from Exempt River Reach Analysis

Results from Erosion potential analysis are presented below:

Exempt River Reach	Area (acres)	Impervious Area (acres) [%]			Ep (Post/Pre) [Criteria<1.05]
		Pre	Post	Increase	
Otay River – West of Interstate 805	29,571	9,428[31.8]	9,473[32.0]	45[0.2]	1.01
San Diego River	111,006	32,106[28.9]	32,777[29.5]	671 [0.6]	1.03
San Dieguito River	28,701	6,008[20.9]	6,042[21.0]	34[0.1]	1.01
San Luis Rey River	225,768	26,216[11.6]	26,803[11.9]	587[0.3]	1.01
Sweetwater River	26,596	10,566[39.7]	10,663[40.1]	97[0.4]	1.03

Results from coarse sediment supply potential analysis are presented below:

Exempt River Reach	Soil Loss (tons/yr.)			Sp (Post/Pre) [Criteria>0.90]
	Pre	Exempt Parcels	Post [Pre – Exempt Parcels]	
Otay River – West of Interstate 805	24,402	38	24,364	1.00
San Diego River	354,619	2,575	352,044	0.99
San Dieguito River	53,549	3,582	49,967	0.93
San Luis Rey River	1,503,964	27,072	1,476,892	0.98
Sweetwater River	16,672	601	16,071	0.96

Based on the results from the analysis it is recommended that exemption be reinstated for Otay River west of Interstate 805, San Diego River, San Dieguito River, San Luis Rey River and Sweetwater River.

Ep #DIV/0!

(No work occurs in existing or future condition for the range of geomorphically significant flows)

Calculations shown below are for reference only - the flow rates are higher than the range of geomorphically significant flows:

Maximum Flow of Record			836.0	3.62	326.77	98.61	3.31	2.56	0.006	1.239	0.000
10-year peak flow			2120.2	6.27	595.18	109.31	5.44	3.56	0.006	2.037	0.000
Critical Shear Flow Rate			2150.0	6.32	600.64	109.52	5.48	3.58	0.006	2.052	0.000

Forester Creek Erosion Potential Analysis for Cross Section 2475 Located between Mission Gorge Road and State Route 52

ATTACHMENT B.1.3

EXCERPT OF VENTURA COUNTY HCP (FINAL DRAFT DATED SEPTEMBER 2013): APPENDIX D, BASIS FOR DESIGNATING NEGLIGIBLE RISK BASED ON CUMULATIVE FUTURE BUILDOUT

APPENDIX D

Basis for Designating Negligible Risk Based on Cumulative Future Buildout

APPENDIX D

BASIS FOR DESIGNATING NEGLIGIBLE RISK BASED ON CUMULATIVE FUTURE BUILDOUT

1. BACKGROUND

Hydromodification impacts are typically most severe just downstream of development and tend to decrease if more undeveloped watershed area contributes to the channel in the downstream direction. Analyses were performed to evaluate thresholds for additional impervious cover, from existing conditions (at the time of the HCP effective date) to buildout conditions, for the area tributary to a susceptible receiving water below which the risk of hydromodification impacts is considered negligible for that channel.

The following results are provided as a function of a susceptible channel's tributary area (A) and median grain size (D_{50}):

- If $A \geq 1$ square mile and $D_{50} \leq 16$ mm, then the threshold of additional imperviousness is evaluated using the nomograph in Figure 3-12.

  Figure 3-12 is based on empirical flow duration equations (Hawley and Bledsoe, 2011), empirical channel geometry relationships (Coleman et al, 2005 and County of San Diego, 2009), and Erosion Potential analyses (see HCP Section 6.3 for a discussion on the Erosion Potential analysis method). The results range from 0.46% to 1.00% additional imperviousness, depending on watershed size and mean annual precipitation (MAP).

- If $A < 1$ square mile and $D_{50} \leq 16$ mm, then the threshold of additional imperviousness is 0.44%. (See Section 6.2 below.)

- If $D_{50} \geq 16$ mm, then the threshold of additional imperviousness is 1.65%. (See Section 6.2 below.)

The analyses used to establish these thresholds are described below.

2. HYDROLOGIC ANALYSIS

2.1 Identify the Typical Range of Rainfall Conditions

For the purposes of this analysis, the typical range of mean annual precipitation (MAP) is assumed to be 14 inches to 18 inches per year because most of the developed regions within Ventura County fall within this range on the isohyetal map (Figure 2-5) and this range is consistent with Ventura County's long-term precipitation gage records

(VCWPD 2007). It is anticipated that future development will impact the most miles of susceptible channel in the Calleguas Watershed within and downstream of the Cities of Thousand Oaks, Simi Valley, and Moorpark. The long-term precipitation records in these areas are all within the 14 inch to 18 inch range and thus these two MAPs were used in this analysis.

Table D-1. Long-Term Precipitation Gage Records in Ventura County

Precipitation Gage ID	Period of Record	Mean Annual Precipitation (inches)
Camarillo #219	1965-2006	13.45
Port Hueneme #17	1891-2006	13.62
Moorpark #141	1949-2006	14.45
Ventura #66	1873-2006	14.71
Simi Valley #154	1948-2006	14.89
Thousand Oaks #128	1943 -2006	15.6
Santa Paula #245	1961-2006	17.35
Piru #36	1927-2006	17.39
Fillmore #199	1959-2006	18.44
Ojai #30	1906-2006	21.32

2.2 Identify the Range of Watershed Areas

The range of typical watershed areas used in the sensitivity analysis were established based on an inventory of a subset of natural drainage channels that have significant urban development in their tributary areas. While there are a few susceptible drainage channels with watershed areas over 100 square miles or less than 1 square mile, most of the susceptible channels downstream of development are lower order with watershed areas ranging from about 2 to 10 square miles. Seven categories of watershed area (1-, 2-, 5-, 10-, 20-, 50-, and 100-square miles) were used in this analysis.

2.3 Identify Length of Daily Flow Record

A 30-year length of daily flow record was assumed in this analysis. During preliminary runs it was found that the threshold of additional impervious cover was not sensitive to changes in the assumed length of daily flow record.

2.4 Calculate Necessary Peak Flow Inputs (Q_2, Q_5, Q_{10})

Empirical peak flow equations used to estimate the 2-, 5-, and 10-year recurrence interval flows (Hawley and Bledsoe, 2011). The general form of the equation is:

$$Q_i = e^{(Incpt)} * A^a * P^p * e^{(impmax * Impmax)}$$

Where:

Q_i	=	the instantaneous peak flow at return interval i years (cfs)
Incpt	=	the vertical axis intercept of the log-transformed linear regression model
A	=	total drainage area (mi^2)
P	=	average annual precipitation (in)
Impmax	=	the maximum spatial extent of the total impervious area during the gage record as a fraction of the total drainage area (mi^2/mi^2)

a, p, and impmax = regression parameters specific to each return period

Table D-2 provides the regression parameters for each return period of interest.

Table D-2. Regression parameters for the 2-, 5-, and 10-year peak flows

Return Period (yrs)	Incpt (-)	a (mi^2)	p (in)	Impmax (-)
2	-0.644	0.667	1.29	8.61
5	2.137	0.838	0.773	3.23
10	2.90	0.868	0.767	0

Table D-3 presents the resulting flowrates for each combination of tributary area and mean annual precipitation analyzed (14 total) assuming no imperviousness.

Table D-3. Peak Flow (Q_2, Q_5, Q_{10}) Results

Tributary Area	Mean Annual Precipitation	Q2	Q5	Q10
A	MAP			
sq mi	in/yr	cfs	cfs	cfs
1	14	15.8	65.2	138
2	14	25.1	116	251

20	18	161	974	2247
50	18	297	2100	4977
100	18	472	3753	9083

2.5 Calculate Inputs for Long-Term Cumulative Durations (Q_{max}, Q_{min}, day1, day2, N_B, $H_{B\text{-}log}$)

In order to represent the mean daily flows with cumulative duration curves, logarithmic histogram bins were created to represent flow frequencies without any discontinuities

following the Hawley and Bledsoe (2011) methodology. The bin size of the logarithmically-spaced histogram bins ($H_{B\text{-}log}$) is represented as follows:

$$H_{B\text{-}log} = \{\ln(Q_{max})\text{-}\ln(Q_{min})\}/(N_B\text{-}1)$$

Where:

Q_{max}	=	the maximum flow of record (cfs)
Q_{min}	=	the minimum flow of record (cfs)
N_B	=	the number of bins

The minimum flow (Q_{min}) was set equal to 0.01 cfs, which represents the lowest non-zero mean daily flow reported at any gage used in the Hawley and Bledsoe (2011) analysis. The number of bins (N_B) was set at 25 to provide a balance between using small enough bin sizes for adequate resolution and ensuring that the flow-record data would be capable of populating each of the bins. The maximum flow of record (Q_{max}) is equivalent to the maximum mean 24-hour flow and is estimated using the following equation:

$$Q_{max}=e^{(-2.24)}*A^{0.979}*P^{1.79}*Yr^{0.341}$$

Where:

A	=	total drainage area (mi^2)
P	=	average annual precipitation (in)
Yr	=	the length of the mean daily flow record (30 years)

Q_{max} is also the scaling factor for the duration density function (DDF), or conditional probability density function, used to predict the cumulative durations of the binned geomorphically-effective flows. A power function is used to represent the duration in days, with the following form:

$$days = day1*Q^{day2}$$

The parameter 'day1' represents the magnitude of the power function calibrated in 'days' and 'cfs' and is estimated using the following relationship:

$$day1 = e^{(-12.9)}*A^{0.676}*P^{3.71}*Yr^{1.85}*e^{(13.8*Impav)}$$

Where:

A	=	total drainage area (mi^2)

P	=	average annual precipitation (in)
Yr	=	the length of the mean daily flow record (30 years)
Impav	=	the average spatial extent of the total impervious area expressed as a fraction of the total drainage area (mi^2/mi^2)

The parameter 'day2' represents the shape of the power function and is calibrated in 'days' and 'cfs' through the following relationship:

$$day2 = -1.60+0.166*\ln(Q_{10})-0.138*\ln(day1)+0.129*\ln(Yr)+0.720*Impav$$

Where:

Q_{10}	=	the instantaneous 10-year peak flow
Yr	=	the length of the mean daily flow record (30 years)
Impav	=	the average spatial extent of the total impervious area expressed as a fraction of the total drainage area (mi^2/mi^2)

2.6 Calculate Long-Term Cumulative Durations for Each Flow Bin (B, $B_{lwr-log}$, $B_{upr-log}$, Q, days)

Using the bin size estimated above (H_{B-log}), the lower and upper bounds of each logarithmically-spaced bin (B) can be calculated as follows:

$$B_{lwr-log} = e^{\{\ln(Qmin)+(B-2)*HB-log\}}$$

$$B_{upr-log} = e^{\{\ln(Qmin)+(B-1)*HB-log\}}$$

The average flow within each of the bins was used in the power function to calculate the cumulative duration for the histogram.

$$Q = (B_{lwr-log}+B_{upr-log})/2$$

$$days = day1*Q^{day2}$$

3. HYDRAULIC ANALYSIS

3.1 Identify a Range of Typical Receiving Channel Geometry Dimensions

An empirical relationship developed by Coleman et al (2005), modified by Stein (County of San Diego, 2009) was used to express channel dimensions (width, depth,

and, to a lesser extent, gradient) as a function of dominant discharge (Q_{bf}, in cfs). The Stein and Coleman relationship was used because it: (1) produced more consistent and conservative results than the Hey-Thorne (1986) relationship; (2) resulted in Qcrit results within the range of values suggested for implementation in the San Diego HMP (0.1Q2, 0.3Q2, 0.5Q2); (3) was general in that it did not require an assumption of D50; and (4) is applicable to the most sensitive sand bedded channels, which the Parker (2007) relationship is not. The geometry relationships are as follows:

$$\text{Width (ft)} = 0.6012 * Q_{bf}^{0.6875}$$

$$\text{Depth (ft)} = 0.3854 * Q_{bf}^{0.3652}$$

Q_{bf}, assumed to be approximately the 5-year peak discharge (Q_5), was estimated using the empirical equation from Hawley and Bledsoe (2011) provided in Section 2.4 of this Appendix. This equation calculates Q_5 (cfs) as a function of watershed area (sq. mi.), mean annual precipitation (MAP, in/yr), and percent impervious cover (%) based on empirical observations of USGS gages.

Manning's equation was used to iteratively find the slope for each channel dimension, such that the wetted cross sectional area at bankfull conveys the Q_5. Manning's equation is expressed as:

$$Q = \frac{1.49 A R^{0.67} S^{0.5}}{n}$$

Where:

Q	=	Flowrate (cfs)
A	=	Cross Section Flow Area (ft^2)
R	=	Hydraulic Radius (ft) = A / P
P	=	Wetted Perimeter (ft)
S	=	Energy Gradient Assumed Equal to Longitudinal Slope (ft/ft)
n	=	Manning Roughness (unitless)

The hydraulic analysis assumed a Manning Roughness value (n) of 0.035 for the main channel, corresponding to a non-vegetated, straight channel with no riffles and pools. This reflects the small, ephemeral receiving channels which are prevalent in Southern California. A relatively low 'n' value was used at the request of the San Diego Regional Water Board in the development of the San Diego HMP. A Manning's roughness of

0.07 was used for the over bank floodplain with an assumed side slope of 10 to 1 (Horizontal:Vertical). The overbank parameters were not as sensitive of parameters as longitudinal slope and channel geometry for the purpose of this analysis, therefore a range was not evaluated.

The receiving channel geometry dimensions used for hydraulic analysis of each model scenario are presented in Table D-4.

Table D-4. Receiving Channel Geometry Dimensions

Tributary Area	Mean Annual Precipitation	Longitudinal Slope	Bankfull Width	Bankfull Depth
A	***MAP***	***S***	***W***	***D***
sq mi	**in/yr**	**%**	**ft**	**ft**
1	14	0.45	10.6	1.8
2	14	0.30	15.8	2.2
5	14	0.18	26.8	2.9
10	14	0.12	40.0	3.6
20	14	0.08	59.7	4.4
50	14	0.05	101.2	5.9
100	14	0.04	150.8	7.3
1	18	0.40	12.1	1.9
2	18	0.27	18.1	2.4
5	18	0.16	30.7	3.1
10	18	0.11	45.7	3.8
20	18	0.07	68.2	4.8
50	18	0.05	115.6	6.3
100	18	0.03	172.4	7.8

3.2 Calculate Effective Shear Stress and Velocity for Each Flow Bin

The flow velocity was calculated after iterating for the slope to achieve $Q=Q_5$ as:

$$V = Q/A$$

Where:

V = Flow Velocity (ft/s)

Q = Flowrate (cfs)

A	=	Cross Section Flow Area (ft^2)

Average boundary shear stress was calculated as:

$$\tau = \gamma R S$$

Where:

τ	=	Effective Shear Stress (lb/ft^2)
γ	=	Unit Weight of Water (lb/ft^3)
R	=	Hydraulic Radius (ft)
S	=	Longitudinal slope (ft/ft)

4. WORK ANALYSIS

4.1 Identify Critical Flowrate (10%Q_2)

The regional default critical flowrate of 10% Q_2, per Appendix E, was used for this analysis. Flow rates below this value were assumed to perform no work on the channel.

4.2 Calculate Work for Each Flow Bin

The simplified effective work equation used is specified in the Ventura County MS4 Permit (LARWQCB, 2010) and is expressed as:

$$W = (\tau - \tau_c)^{1.5} V$$

Where:

W	=	Work [dimensionless];
τ	=	Effective Shear Stress [lb/ft^2];
τ_c	=	Critical Shear Stress [lb/ft^2];
V	=	Flow Velocity [ft/s]

If the effective shear stress for a given flow bin is less than the critical shear stress, then the effective work is equal to zero.

5. CUMULATIVE WORK ANALYSIS

Cumulative work is a measure of the long-term total work or sediment transport capacity performed at a creek location. It incorporates the distribution of both discharge magnitude and duration for the full range of flowrates simulated. To calculate cumulative work, first the work and duration associated with each flow bin is multiplied. Then the cumulative work for all flow bins is summed to obtain total work. This analysis can be expressed as:

$$W_t = \sum_{i=1}^{n} W_i \, \Delta t_i$$

Where:

W_t	=	Total Work [unitless]
W_i	=	Work per flow bin [unitless]
Δt	=	Duration per flow bin [days]
n	=	number of flow bins

6. EROSION POTENTIAL ANALYSIS

Ep is calculated by simply dividing the total work of the post-project condition by that of the pre-project condition. Ep is expressed as:

$$E_p = W_{t,post} / W_{t,pre}$$

Where:

E_p	=	Erosion Potential [unitless]
$W_{t,post}$	=	Total Work associated with the post-project condition [unitless]
$W_{t,pre}$	=	Total Work associated with the pre-project condition [unitless]

6.1 Iterate % Impervious Cover to Meet the Hydromodification Management Standard (Ep < 1.05)

Considering that the Hydromodification Management Standard for Ventura County aims to "maintain the Ep in-stream at a value of 1.0", it is assumed that an Ep value less than 5% of the target value meets the Management Standard (i.e., an Ep value of 1.04 rounds to 1.0). Additional basis for the use of a +/- 5% allowance on Ep is supported in Section 6.3.7 in the HCP. An iterative process was used to determine the percentage of

impervious cover that meets the hydromodification management standard (Ep < 1.05). The percent imperviousness is an input for the DDF power function coefficient and exponent (day1 and day2, respectively) and modifies the duration of flows within each of the logarithmically-spaced flow bin. The new durations (days) for each flow bin are multiplied by the work per flow bin (W_i) and summed across all bins to arrive at a new value for total work associated with the post-project condition ($W_{t,post}$) and Erosion Potential (Ep). Percent impervious cover is subsequently adjusted until an E_p of 1.05 is converged upon.

In preliminary runs it was evaluated that the threshold additional impervious cover associated with Ep equal to 1.05 was not highly sensitive to the baseline pre-development (or existing condition) imperviousness. For example, an increase in imperviousness from 0% to 1% resulted in the same Ep as an increase from 10% to 11%. The resulting thresholds of additional imperviousness from existing (at the time of the HCP effective date) to buildout conditions are provided below in Table D-5 and in Figure 3-12. The results provided used an existing imperviousness of 0%.

Table D-5: Threshold Additional Imperviousness Results

Tributary Area	**Mean Annual Precipitation**	**Threshold Additional Imperviousness**	**Pre-Project Total Cumulative Work**	**Post-Project Total Cumulative Work**	**Erosion Potential**
A	***MAP***	***Impav***	***Wt, pre***	***Wt, post***	***Ep***
sq mi	**in/yr**	**%**	--	--	--
1	14	0.46	1.67	1.75	1.05
2	14	0.50	1.52	1.59	1.05
5	14	0.56	1.45	1.52	1.05
10	14	0.61	1.48	1.55	1.05
20	14	0.68	1.59	1.67	1.05
50	14	0.80	1.89	1.98	1.05
100	14	0.92	2.27	2.39	1.05
1	18	0.48	2.69	2.82	1.05
2	18	0.52	2.44	2.57	1.05
5	18	0.59	2.12	2.23	1.05
10	18	0.65	2.07	2.17	1.05
20	18	0.72	2.12	2.23	1.05
50	18	0.85	2.25	2.36	1.05
100	18	1.00	2.54	2.67	1.05

6.2 Thresholds of Additional Imperviousness Based on Hawley and Bledsoe (2013)

For susceptible channels with a tributary area less than one square mile, the threshold of additional imperviousness below which the risk of hydromodification impacts is considered negligible for that channel is 0.44%. This result is based on equating two of the channel enlargement equations listed in Hawley and Bledsoe (2013) and solving for an Ep of 1.05. The two enlargement functions are:

$$Ar = 1.18*Ep^{0.998}$$

and

$$Ar = 1.18*e^{(11.0*Imp)}$$

Where:

Ar = Enlargement expressed as the relative magnitude

Ep = Sediment-transport capacity load ratio between 25-yr post-developed and pre-developed DDF simulations

Imp = Total impervious area as a fraction of total drainage area

The following equation expresses Imp as a function of Ep:

$$Imp = (0.998/11) * \ln(Ep)$$

Assuming Ep is equal to 1.05, the resulting Imp is 0.44%.

For susceptible channels with a median grain size (D_{50}) greater than 16 mm, a +/- 20% allowance on Ep is supported in Section 6.3.7 in the HCP. Assuming an Ep of 1.20 and using the equation above, the threshold additional imperviousness, below which the risk of hydromodification impacts is considered negligible for that channel, is 1.65%.

EXECUTIVE SUMMARY

In accordance with Order No. R9-2013-0001, issued by the California Regional Water Quality Control Board (Municipal Permit), projects that are subject to Priority Development Project requirements must incorporate: 1) Treatment control best management practices, and 2) Flow-control requirements to address potential hydromodification impacts to downstream natural (non-hardened) channels.

However, certain improved/hardened drainage systems are not impacted by channel erosion. For these cases, the Municipal Permit includes provisions where a local agency may provide exemptions from hydromodification:

> *Each Copermittee has the discretion to exempt a Priority Development Project from hydromodification management BMP performance requirements of Provisions E.3.c.(2) where the project discharges water runoff to:*
>
> *(i) Existing underground storm drains discharging directly to water storage reservoirs, lakes, enclosed embayments, or the Pacific Ocean.*
>
> *ii) Conveyance channels whose bed and bank are concrete lined all the way from the point of discharge to water storage reservoirs, lakes, enclosed embayments, or the Pacific Ocean;*

Having development/redevelopment projects explore HMP exemption criteria could require an individual project proponent to undertake significant engineering analyses and evaluation of downstream drainage facilities and conditions within a watershed area. Consequently, the City of Carlsbad's Land Development Engineering Division commissioned this hydromodification exemption study.

This report focuses on certain watershed areas tributary to the Agua Hedionda Lagoon, Batiquitos Lagoon, and Buena Vista Lagoon. All three Lagoons are located within the Carlsbad Watershed area and are considered enclosed embayments per the Municipal Permit.

The study limits focus on select areas draining to the lagoons that are highly-developed and are served by improved existing paved streets that collect and convey runoff via reinforced concrete pipes (hardened systems) that are not subject to erosion potential. For each storm drain network discharging to the lagoon, the discharge locations were evaluated to ensure they qualify as a 'direct discharge'. To qualify as a direct discharge, field visits were performed at each outlet location to verify properly sized energy dissipation and, by a review of record drawings, that the discharge locations are below the 100-year flood elevation of the lagoon (consistent with Watershed Management Area Analysis (WMAA) for the San Diego River). Pictures of the outlet locations are at the end of this study.

The HMP Exemption Exhibit in the map pocket at the back of this report includes the limits of the study areas. For those projects located within a hatched area, they are considered exempt from hydromodification requirements either under current conditions or with some future

improvements. In accordance with the Municipal Permit, projects that are exempt from hydromodification must still satisfy all other applicable storm water standards (i.e.: site design, source control measures, treatment control best management practices, low impact development, etc.).

Although several watershed areas were evaluated, not all drainage areas qualified for exemption from hydromodifcation requirements. These reasons why they did not qualify will be explained further in the study and are, therefore, not included as exempt areas in the HMP Exemption Exhibit.

INTRODUCTION

In accordance with the Municipal Permit, development and redevelopment projects are subject to either: 1) Standard Stormwater or 2) Priority Development Project (PDP) requirements, which are more rigorous. The City's "Storm Water Standards Questionnaire E-34" (see Figure 11) is used to determine whether a project must meet Standard Stormwater or PDP requirements. The questionnaire, using criteria from the Municipal Permit, provides specific thresholds under which these new development/redevelopment projects trigger PDP requirements.

Among other things, projects subject to PDP requirements must include treatment control best management practices (BMPs) and are required to incorporate hydromodification BMPs. Hydromodification provides requirements to control post-development storm water runoff rates, velocities, and durations in order to maintain or reduce pre-development downstream erosion, sediment pollutant generation, and protect beneficial uses and stream habitat.

For this study, a focus was made to look at the three lagoons within the city (Buena Vista, Agua Hedionda, and Batiquitos Lagoon) and explore applicable HMP exemptions. This study assesses the lagoons and seven (7) major drainage areas contributing to the lagoons to determine whether they meet hydromodification exemption criteria. The seven major drainage areas are tributary to one of the seven following storm drain outlets into Buena Vista, Agua Hedionda, or Batiquitos Lagoon (see the Study Area Exhibits and HMP Exemption Exhibit in the map pocket):

Buena Vista Lagoon

- 48" and 66" outlets on the east side of Carlsbad Boulevard into the south side of the lagoon
- 48" outlet on the west side of Interstate 5 into the south side of the lagoon
- 66" outlet on the west side of Jefferson Street into the south side of the lagoon

Agua Hedionda Lagoon

- 18" outlet on the west end of Date Avenue into the north side of the lagoon
- 84" outlet on the east side of the railroad tracks into the north side of the lagoon
- 60" outlet near the south end of Marina Drive into the north side of the lagoon

Batiquitos Lagoon

- 84" outlet on the east side of Carlsbad Boulevard into the north side of the lagoon

With the exception of one area, the studied tributary areas do not include natural (non-hardened) channels directly to a lagoon. Each of these major drainage areas is served by a network of improved (hardened) public drainage facilities that outlet into a lagoon. The majority of the public facilities are underground storm drain systems or paved streets. Some facilities are also lined (concrete, gunite, etc.) drainage ditches or swales. Provided runoff from the study area discharges into a non-erodible drainage network that is continuous with a direct discharge to a lagoon, it is potentially eligible for a hydromodification exemption. Based on record drawing research and field reconnaissance, the Study Area Exhibits identify the improved (hardened) drainage networks. The exhibits demonstrate that each major drainage area, except the 48" outlet

towards Buena Vista Lagoon on the west side of Interstate 5, contains a continuously improved non-erodible network that serves the drainage area; therefore MS4's draining directly into the lagoons are not subject to potential impacts from hydromodification. The discharge points must be below the 100-year water surface elevations in the lagoon (consistent with Watershed Management Area Analysis (WMAA) for the San Diego River).

Areas Draining to Buena Vista Lagoon

Using rational method analyses from the 2003 County *Hydrology Manual* and as-built (record drawing) research, the existing storm drain network collecting run-off for all of the Buena Vista Lagoon drainage areas (Major Drainage Basins 100, 200, and 300 as shown on the Study Area Exhibits) analyzed in this report have been shown to be adequate to convey the Q_{10} runoff, which is the upper range for hydromodification as described the Municipal Permit. Each outlet structure was observed to ensure they include adequate energy dissipation to address erosion potential. For details of how these each of these criteria where satisfied, refer to the Appendices of this study. The select areas draining to the Buena Vista Lagoon from Major Drainage Basins 100 and 300, which are determined to be exempt from HMP are shown in the HMP Exemption Exhibit.

Although Major Drainage Basin 200 includes an improved non-erosive (hardened) storm drain system, the existing 48" outlet is not directly adjacent to the waters edge of Buena Vista Lagoon; therefore, does not qualify as a direct discharge to an exempt water body. In order for Major Drainage Basin 200 to qualify for an exemption a non-erodible drainage facility capable of conveying at least the 10-year flow will need to be constructed from the existing 48" outlet to the 100-year floodplain in the receiving lagoon.

Areas Draining to Agua Hedionda Lagoon and Batiquitos Lagoon

Certain drainage areas that drain to these lagoons were selected (Major Drainage Basin 400, 500, 600, and 700 as shown on the Study Area Exhibits). The existing storm drain network for each drainage area was also evaluated against their ability to carry the Q10. As provided in the Technical Appendices, the storm drain system for each drainage areas has the capacity to carry the Q10. The outlet for each storm drain system was also observed to ensure they include adequate energy dissipation to address erosion potential. For details of how these each of these criteria where satisfied, refer to the Appendices of this study. Based on these findings, the select areas draining to Agua Hedionda Lagoon and Batiquitos Lagoon are shall be considered exempt from HMP. These exempt areas are shown in the HMP Exemption Exhibit.

There are two isolated areas within Major Drainage Basin 600 that direct storm runoff over the natural ground surface west of the railroad tracks. Without further analysis using erosion potential (or equivalent), the naturally-lined swales are not considered exempt from hydromodification. Therefore, these areas were excluded from the exemption area in HMP Exemption Exhibit and from further analysis.

OUTLET CONDITIONS

Since the storm drain networks considered in this report are continuously non-erodible to one of the three lagoons (except from Major Drainage Basin 200 and a portion of 600), the energy dissipation to be studied are at the lagoon outlets. As-built drawings were reviewed and a site visit was performed to determine the conditions at each outlet. The following describes the findings for each outlet. In addition, the Lagoon Assessment section contained next in this report confirms that each outlet is below the 100-year water surface elevation. This effort confirms the storm drain network (MS4's) qualifies as a 'direct discharge' to an exempt water body.

Buena Vista Lagoon 48" and 66" Outlets

These are adjacent reinforced concrete pipe outlets that discharge into the south edge of Buena Vista Lagoon immediately east of the merge of State Street and Carlsbad Boulevard. During the site visit, the lagoon water level was at the invert of the 48" outlet and just above the invert of the 66" outlet (see Figure 1 after this report text). Riprap energy dissipation was not observed below the outlets nor was there evidence of erosion below the outlets (see Figure 2).

Drawing No. 215-9 shows that the invert elevation of the 66" reinforced concrete pipe outlet is at 6.0 feet NGVD 29 (the reference drawings are included on the compact disc in the map pocket). The 48" outlet is shown on Drawing 153-9, but the plan does not identify the vertical datum. Based on the site visit, the 48" outlet invert is approximately 6 inches higher than the 66" outlet invert. Buena Vista Lagoon contains a weir structure near the Pacific Ocean that controls the water surface in the lagoon. A field survey by Algert Engineering revealed that the top of the weir structure is at 7.6 feet NAVD 88 or 5.5 feet NGVD 29. Therefore, the water level in the lagoon will be within at least 6 to 12 inches of the outlets. During most periods, the water level should be higher than 5.5 feet due to natural sand build-up above the weir crest caused by littoral processes as well as backwater in the lagoon. Since ponded water is an effective energy dissipater, the 48" and 66" outlets contain proper energy dissipation. This is further evidenced by the absence of erosion below the outlets even though they have been in place since at least the mid-1980's.

Buena Vista Lagoon 48" Outlet

This 48" reinforced concrete pipe is a Caltrans facility whose outlet discharges towards, but not directly into, the south edge of Buena Vista Lagoon immediately west of Interstate 5. The as-built plans (Document No. 40002483) show that the outlet is at elevation 22.0 feet and was designed with "rock slope protection." During the site visit, riprap was observed below the 48" outlet (see Figure 3). The typical riprap diameter was over 12 inches, which is consistent with the sizing proposed on the design plans. Tall grasses obscured some of the riprap, but the grass indicates that the energy dissipation is effective. However, since this outlet is not a 'direct' discharge to the lagoon (see Lagoon Assessment section), no further analysis is provided.

Buena Vista Lagoon 66" Outlet

This 66" reinforced concrete pipe discharges into the south edge of Buena Vista Lagoon immediately west of Jefferson Street. The as-built plans (Drawing No. 182-10) show that the outlet invert is at elevation 5.3 feet NGVD 29 and contains ¼-ton riprap. The outlet invert was just below the lagoon water level (see Figure 4) during the site visit, which is consistent with the

weir-controlled lagoon water level. Riprap was not observed at the outlet during the site visit due to the difficulty in accessing the outlet through the dense vegetation. However, the fact that the water level will be at or above the outlet invert indicates that this outlet has appropriate energy dissipation.

Agua Hedionda Lagoon 18" Outlet

This 18" corrugated metal pipe discharges onto a riprap-lined revetment protecting the northeast bank of Agua Hedionda Lagoon immediately west of the intersection of Date Avenue with Garfield Street (see Figure 5). Storm runoff flows a short distance down the revetment and into the lagoon. As-built plans (Drawing No. 133-3) show that the outlet invert is at elevation 5.36 feet and that energy dissipation has been designed below the outlet. In addition, the tributary drainage area covers approximately 5.2 acres, so the pipe flows will be relatively small.

Agua Hedionda Lagoon 84" Outlet

This 84" reinforced concrete pipe discharges into the north edge of Agua Hedionda Lagoon just east of the railroad tracks. The engineering plans (Drawing No. 360-5) were as-built in 2006, so this is a relatively recent system. The plans show that the storm drain system and its grouted riprap energy dissipater were designed for the 100-year storm flow in accordance with current engineering criteria. A site visit confirmed that the grouted riprap energy dissipater exists and is in substantial conformance with the plans (see Figure 6).

Agua Hedionda Lagoon 60" Outlet

This 60" reinforced concrete pipe discharges directly into the north edge of Agua Hedionda Lagoon just west of Marina Drive. The as-built plans (Drawing No. 152-3) show that the outlet invert elevation is -1.75 feet NGVD 29. This elevation is lower than mean sea level, so the lagoon water level will serve as appropriate energy dissipation for the outflow. A site visit confirmed that the invert is lower than the lagoon water level (see Figure 8).

Batiquitos Lagoon 84" Outlet

This 84" reinforced concrete pipe discharges into the north edge of Batiquitos Lagoon just east of Carlsbad Boulevard and west of the railroad tracks. The as-built drawings (Drawing No. 337-9) show that the storm drain system and its energy dissipater (1-ton riprap and concrete sill) were designed for the 100-year storm flow in accordance with current engineering criteria. A site visit confirmed that the energy dissipater exists in substantial conformance with the plans (see Figure 9).

Summary

For those outlets that qualify as direct discharges, the above information confirms that proper energy dissipation currently exists at each of the storm drain outlet locations for the drainage areas. The dissipation is provided by either riprap or the water level in a lagoon.

DISCHARGE TO LAGOONS

The October 3, 2014, *San Diego River Watershed Management Area Analysis,* states that "to qualify for the potential [hydromodification] exemption, the outlet elevation must be between the river bottom elevation and the 100-year floodplain elevation and properly designed energy dissipation must be provided." Proper energy dissipation was verified in the prior section. This section discusses the 100-year floodplain elevations. Research was performed to determine the 100-year water surface elevations in each of the three lagoons. FEMA provides 100-year floodplain information for many waterbodies. FEMA defines a 100-year floodplain for the lagoons, but does not provide the necessary water surface elevations. However, Dokken Engineering (Dokken) performed detailed HEC-RAS hydraulic analyses of each lagoon as part of their December 2008, *Interstate 5 North Coast Floodplain Studies,* for Caltrans. Relevant excerpts from the Dokken studies are included in the Appendices. Table 1 summarizes the outlet elevations of each discharge point from the as-built drawings (discussed in the prior section) and the associated 100-year floodplain elevation from the Dokken studies. The as-built drawings are either identified as being on NGVD 29 datum or were prepared prior to 1988, so by default should be on NGVD 29. On the other hand, the Dokken studies are on NAVD 88 datum. Corpscon is provided by the US Army Corps of Engineers for coordinate conversions, and shows that 2.2 feet is added to the NGVD 29 elevations to convert to NAVD 88 elevations.

Major Drainage Basin	Description	Outlet Elevation, feet[1]	Lagoon 100-Year Water Surface Elevation, feet[2]
100	Buena Vista Lagoon 48" and 66" Outlets	6.00	13.93
200	Buena Vista Lagoon 48" Outlet	22.00	13.89
300	Buena Vista Lagoon 66" Outlet	5.30	15.75
400	Agua Hedionda Lagoon 60" Outlet	-1.75	12.33
500	Agua Hedionda Lagoon 18" Outlet	5.36	11.68
600	Agua Hedionda Lagoon 84" Outlet	7.95	12.21
700	Batiquitos Lagoon 84" Outlet	6.27	8.90

[1]Elevations are on NGVD 29 (add 2.2 feet to convert to NAVD 88)
[2]Elevations are on NAVD 88

Table 1. Summary of Storm Drain Outlet Elevations and Lagoon Elevations

Table 1 shows that all of the storm drain outlets (with the conversion applied) except at Major Drainage Basin 200 are below the 100-year water surface elevation in the associated lagoon. Therefore, the hydromodification exemption requirement to have the outlet elevation below the 100-year floodplain elevation is met except at Major Drainage Basin 200.

Summary
The four drainage areas (Major Drainage Basins 400, 500, 600, 700) tributary to the Agua Hedionda Lagoon and Batiquitos Lagoon are served by an improved (non-erosive) street and underground storm drains system and have capacity to convey the 10-year rain event condition. The storm drain outlets for these drainage areas to the lagoon are considered direct discharges. Therefore, these areas are considered exempt from hydromodification.

The easterly and westerly drainage areas (Major Dainage Basins 100 and 300) tributary to and outletting directly into Buena Vista Lagoon are served by an improved (non-erosive) street and underground storm drains system and have capacity to convey the 10-year rain event condition. The storm drain outlets for these drainage areas to the lagoon are considered direct discharges. Therefore, these areas are also considered exempt from hydromodification.

The westerly drainage areas (Major Drainage Basin 200) tributary to and outletting adjacent to the Buena Vista Lagoon west of Interstate 15 is served by an improved (non-erosive) street and underground storm drains system and have capacity to convey the 10-year rain event condition. However, this outlet is not considered a direct discharge. In order to create a direct discharge, drainage improvements will need to be constructed that are capable of conveying the 10-year flow to the lagoon. The new outlet must have proper energy dissipation and extend below the 100-year water surface elevation. If such improvements are constructed in the future, this area can be considered as exempt from hydromodification.

HYDROLOGIC AND HYDRAULIC ANALYSES

As mentioned in the Introduction, hydromodification applies to flows up to the 10-year event. Consequently, the drainage network (storm drain pipes, streets, etc.) within each major drainage area are required to convey the 10-year flow in order to qualify for an exemption. All of the available as-built plans for the public storm drain systems in the seven major drainage areas were obtained and reviewed. Several of the more recent as-built plans list 10- or 100-year flow rates in the pipes and/or hydraulic grade lines on the storm drain profiles. These systems have been identified on the Study Area Exhibits and further analyses were not required since the systems have been designed to convey the 10-year or greater flow rates. Therefore, development within these areas is exempt from HMP.

Hydrologic and hydraulic analyses have been performed for the remaining systems whose plans do not contain the flow or hydraulic grade line data. The hydrologic analyses were performed to determine the ultimate condition 10-year flow rates. The County of San Diego's 2003 *Hydrology Manual* rational method procedure was used for the 10-year hydrologic analyses. The rational method input parameters are summarized below and the supporting data is included in Appendix B:

- Precipitation: The 10-year, 6- and 24-hour precipitation values are 1.7 and 3.1 inches, respectively, for the drainage areas tributary to Buena Vista and Agua Hedionda Lagoon. The 10-year, 6- and 24-hour precipitation values are 1.7 and 2.9 inches, respectively, for the drainage areas tributary to Batiquitos Lagoon.

- Drainage subbasin: The drainage subbasins were delineated from the City's 2005 2-foot contour interval topographic mapping, the City's GIS storm drain network, available as-built plans, and a site investigation. See the Study Area Exhibits in the map pocket for the major and subbasin boundaries, rational method node numbers, and subbasin areas.

- Hydrologic soil groups: The hydrologic soil groups were determined from the *San Diego County Soils Interpretation Study* maps for Encinitas and Rancho Santa Fe. The soil group in the study area is primarily A with some pockets of C and D.

- Runoff coefficients: The runoff coefficients were assigned based on the underlying land uses and soil groups. The land uses range from undisturbed areas to commercial/industrial development. The land uses were determined from a 2009 aerial photograph from the City and 2010 Google Earth aerials as well as a site investigation. For undeveloped areas that could be subject to development, a developed condition was assumed. Therefore, the hydrologic analyses essentially model a fully built-out condition. This approach is similar to what would be done for a storm water master plan.

- Flow lengths and elevations: The flow lengths and elevations were obtained from the topographic mapping and engineering plans.

The 10-year rational method analyses were performed using CivilDesign's San Diego County Rational Hydrology Program and the results are included in Appendix B. Separate analyses were performed for the major drainage areas and are labeled as follows:

Buena Vista Lagoon

- Major Basin 100 is tributary to the 48" and 66" outlet on the east side of Carlsbad Boulevard
- Major Basin 200 is tributary to the 48" outlet on the west side of Interstate 5
- Major Basin 300 is tributary to the 66" outlet on the west side of Jefferson Street

Agua Hedionda Lagoon

- Major Basin 400 is tributary to the 60" outlet at the south end of Marina Drive
- Major Basin 500 is tributary to the 18" outlet at the west end of Date Avenue
- Analyses were not performed for the 84" outlet on the east side of the railroad tracks because flow rates and hydraulic grade lines were provided on the majority of the as-built plans.

Batiquitos Lagoon

- Analyses were not performed for the 84" outlet on the east side of Carlsbad Boulevard because flow rates and hydraulic grade lines were provided on the majority of the as-built plans.

The CivilDesign rational method analyses include pipeflow routines for modeling flow in circular pipes. The upstream and downstream invert elevations and pipe length are entered in the model for each storm drain segment. The program then determines the required normal depth pipe size based on the calculated 10-year flow rate, longitudinal slope, and roughness coefficient. The pipeflow routines were used to assess the adequacy of the existing pipes. Invert elevations were selected so that the longitudinal slope from the as-built plans was accurately modeled in the analyses. The longitudinal slope of each storm drain segment was determined from a review of all relevant as-built plans. Some storm drain segments contain varying or multiple slopes. In this case, the flattest slope was used because it will result in the most conservative sizing. A few segments were missing elevations on the as-built plans. For these segments, the average street slope was used. The pipe size from the hydraulic analyses were then compared to the size from the as-built plans to identify pipes with adequate capacity and those with deficiencies.

Since the rational method program determines the minimum required pipe size to convey the 10-year flow in each specific segment, it is possible that program will show the required size increasing or decreasing in adjacent segments of the overall storm drain system. For instance, if the same flow rate is conveyed in two adjacent segments, but the downstream segment has a steeper longitudinal slope, the results can show that the downstream pipe is smaller. Engineering design criteria typically does not allow subsequent segments in a storm drain system to be smaller. However, since the rational method results are merely used as a comparison with the sizes from the as-built plans, any usual telescoping effects are not relevant.

The pipes have been categorized based on their capacity and identified on the Study Area Exhibits per their category. The first category represents pipes in which the as-built plans contain flow rate or hydraulic grade line information indicating that the pipes can convey the 10-year runoff. As mentioned above, analyses were not specifically performed for these systems since detailed information is contained on the as-built plans. The second category represents pipes in which the rational method analyses show that the existing size can convey the 10-year flow rate. The third category represents pipes in which the rational method analyses show that the existing pipes need to be upsized by at most one pipe size (6 inches) to convey the 10-year flow. The fourth category represents pipes in which the rational method analyses show that the existing pipes need to be upsized by more than one pipe size to convey the 10-year flow.

The first and second categories represent no major deficiencies in capacity. The third category indicates that the existing pipe is slightly undersized. However, if pressure flow and street capacity are considered, these systems will be capable of conveying the 10-year flows since the additional flow associated with an at most 6 inch increase in pipe size can be conveyed under pressure or within the adjacent street. This was confirmed by comparing the 10-year flow rates with a street flow capacity chart. For a given pipe segment, the street flow capacity chart indicated that the associated street can convey the required flow. Therefore, the drainage systems within the first three categories have capacity for the 10-year flow.

Existing pipes under the fourth category require additional review to determine whether the 10-year flow can be conveyed. Additional review resulted in the following assessment of the storm drain systems within the fourth category.

Major Basin 100

There are four storm drain segments in Major Basin 100 that fall within the fourth category. The segments are between rational method nodes 105 to 109, 135 to 136, 137 to 138, and 138 to 141. The following assesses the pipe and street capacity of each of these four segments.

The existing pipe from nodes 105 to 109 has an 18” diameter with a normal depth capacity of approximately 10 cubic feet per second (cfs). However, the rational method results show that the 10-year flow rate is 37 cfs, and the pipe size needed to convey 37 cfs varies from 30” to 33”. The corridor along the street between these nodes has capacity for the additional 27 cfs (37 – 10 = 27 cfs) needed beyond the pipe capacity. Therefore, the combined pipe and street in this area can convey the 10-year flow.

A similar assessment is made for the other three segments. The existing pipe from nodes 135 to 136 is a 24” reinforced concrete pipe (RCP), while the analyses show that a 33” RCP is needed. The existing pipe from nodes 137 to 138 is a 36” RCP while the analyses show that a 45” RCP is needed. The existing pipe from nodes 138 to 141 is a 12” RCP while the analyses show that a 30” RCP is needed. For each of these deficient segments, the associated streets can handle the additional capacity needs. In addition, the adjacent upstream and downstream pipe segments are not deficient. Therefore, the overall drainage systems along these nodes can convey the 10-year flow.

Major Basin 300

There are two storm drain segments in Major Basin 300 that fall within the fourth category. The segments are between rational method nodes 309 to 316 and nodes 340 to 343. The existing pipes from nodes 309 to 316 are 24" RCPs, while the required pipe varies from 36" to 39". The existing pipes from nodes 340 to 343 are 66" RCPs, while the required size varies from 78" to 81". For both of these areas, the associated streets can handle the additional capacity needs, so these areas can convey the 10-year flow.

Major Basin 400

There are two storm drain segments in Major Basin 400 that fall within the fourth category. The segments are between rational method nodes 408 to 409 and 418 to 420. The existing pipe between nodes 408 and 409 is an 18" RCP, while a 30" RCP is needed. This pipe crosses a sump in the street. The excess stormwater will pond in the street until it drains through the 18" RCP. Therefore, the 10-year flow will be detained in this area. In addition, there are no natural streams in the vicinity that would be subject to HMP requirements.

The existing pipe between nodes 418 and 420 is a 60" RCP that outlets into Agua Hedionda Lagoon, while the analyses show that a 72" RCP is required. However, a 60" bypass structure near the upper end of this segment can divert a portion of the runoff to a second outlet that discharges to a cove connecting to Agua Hedionda Lagoon. The as-built plans (Drawing No. 152-3) show that the bypass is controlled by stop logs. If the bypass is open, then the pipe capacity below the bypass will be sufficient for the 10-year flow. The City of Carlsbad's Utilities Operations staff has a "Weir Wall Removal Procedure," so the stop logs will be removed during high flow events to ensure 10-year flow capacity. Therefore, this area conveys the 10-year runoff to Agua Hedionda Lagoon.

CONCLUSION

The City of Carlsbad's final HMP outlines conditions under which a Priority Development Project can be exempt from hydromodification requirements. The purpose of this study is to explore HMP exemptions based on the January 2011 Carlsbad SUSMP and Order No. R9-2013-0001 adopted by the Regional Water Quality Control Board. In particular, this study examines the criteria necessary for HMP exemptions for 1) enclosed embayments (lagoons) and 2) stabilized conveyances to exempt systems.

These analyses have been performed for seven major drainage areas selected by the City of Carlsbad and are summarized below based on the two primary criteria that were investigated. Additional criteria must be met in addition to the primary criteria to achieve an exemption. The additional criteria is also summarized below.

Stabilized Conveyances with Energy Dissipation

The hydrologic and hydraulic analyses show that the 10-year flow is conveyed by the underground storm drain alone in most areas, and the combination of the underground storm drain and improved public streets in the remaining areas. In addition, each storm drain outlet into

a lagoon has proper energy dissipation. Therefore, each study area contains an underground storm drain or conveyance channel that discharges directly to an enclosed conveyance.

Lagoon Floodplains

A comparison of as-built drawings with a recent detailed HEC-RAS analysis of each lagoon confirmed that each outlet is below the 100-year floodplain except in Major Drainage Basin 200. Each outlet is also at or above the associated lagoon floor. Therefore, each outlet except in Major Drainage Basin 200 meets the floodplain criteria for a hydromodification exemption. Major Drainage Basin 200 can meet the criteria if its non-erodible drainage system is extended to the lagoon.

Future Projects

Based on the findings in this report, future projects within one of the studied drainage areas (except Major Drainage Basin 200) qualify for an exemption if their storm runoff is directed to a public drainage facility included in this report without being conveyed over a natural drainage course.

However, future projects in certain locations within the study area will be required to perform additional analyses prior to receiving a hydromodification exemption. These exceptions are outlined below.

The major drainage area tributary to the 84” outlet into Agua Hedionda Lagoon is bisected along its westerly side by the existing railroad tracks. Storm runoff from two areas west of the tracks will be directed to naturally-lined swales near the tracks. Since naturally-lined swales prevent a hydromodification exemption, development west of the tracks may need to replace a natural swale with a non-erodible conveyance. It will be the responsibility for a future development project west of the tracks to assess this situation in detail and propose a solution, as needed. The HMP Exemption Exhibit delineates the two non-exempt areas for reference. Hydrologic analyses have not been performed for these two areas.

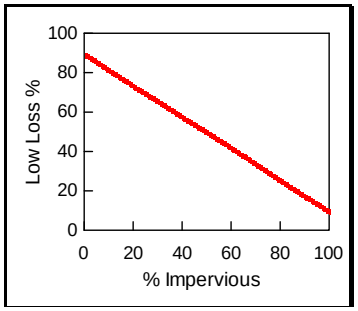
Attachment K. Riverside County Flood Control Interim Criteria

INTERIM CRITERIA FOR SIZING INCREASED RUNOFF DETENTION FACILITIES

* The entire area of proposed development will be routed through a detention facility(s) to mitigate increased runoff. All basins must have positive drainage; dead storage basins shall not be acceptable.

* Storms to be studied will include the 1-hour, 3-hour, 6-hour and 24-hour duration events for the 2-year, 5-year and 10-year return frequencies. Detention basin(s) and outlet(s) sizing will ensure that none of these storm events have a higher peak discharge in the "after" condition than in the "before" condition.



* For the 2-year and 5-year events the loss rate will be determined using an AMC I condition. For the 10-year event AMC II will be used. Constant loss rates shall be used for the 1-hour, 3-hour and 6-hour events. A variable loss rate shall be used for the 24-hour events.

* Low Loss rates will be determined using the following:

  - Undeveloped Condition --> *Low Loss = 90%*

  - Developed Condition --> *Low Loss = .9 - (.8 x % impervious)*

  - Basin Site --> *Low Loss = 10%*

* Where possible and feasible the on-site flows should be mitigated before combining with off-site flows to minimize the size of the detention facility required. If it is necessary to combine off-site and on-site flows into a detention facility two separate conditions should be evaluated for each duration/return period/before-after development combination studied; the first for the total tributary area (off-site plus on-site), and the second for the area to be developed alone (on-site). It must be clearly demonstrated that there is no increase in peak flow rates under either condition (total tributary area or on-site alone), for each of the return period/duration combinations required to be evaluated. A single plot showing the pre-developed, post-developed and routed hydrograghs for each storm considered, shall be included with the submittal of the hydrology study.

* No outlet pipe(s) will be less than 18" in diameter. Where necessary an orifice plate may be used to restrict outflow rates. Appropriate trash racks shall be provided for all outlets less than 48 inches in diameter.

* The basin(s) and outlet structure(s) must be capable of passing the 100-year storm without damage to the facility.

* Mitigation basins should be designed for joint use and be incorporated into open space or park areas. Side slopes should be no steeper than 4:1 and depths should be minimized where public access is uncontrolled.

* A viable maintenance mechanism, acceptable to both the County and the District, should be provided for detention facilities. Generally, this would mean a CSA, landscape district, parks agency or commercial property owners association. Residential homeowners associations would generally not be acceptable.

1 INTRODUCTION

The San Diego Regional Water Quality Control Board (Regional Water Board) issued Waste Discharge Requirements for Discharges from the Municipal Separate Storm Sewer Systems (MS4s) draining the jurisdictional areas of the Counties of Riverside and San Diego, the Riverside County Flood Control and Water Conservation District (RCFCWCD), and the Cities of Murrieta, Temecula, and Wildomar (collectively known as Copermittees) as well as the City of Menifee within the San Diego Region, Order No. R9-2013-0001 as amended by Order Nos. R9-2015-0001 and R9-2015-0100, National Pollutant Discharge Elimination System (NPDES) Permit No. CAS0109266, hereafter referred to as the Permit. This appendix establishes procedures within the Santa Margarita River (SMR) subwatershed (Hydrologic Unit No. 902) in the San Diego Region for compliance with the Monitoring and Assessment Program (MAP) requirements under Provisions B.4 and Provision D of the Permit, and is effective upon acceptance of the Santa Margarita River Watershed Management Area (WMA) Water Quality Improvement Plan (WQIP) as required by the Permit.

Implementation of the MAP will be led by the RCFCWCD in the Upper and Middle SMR subwatersheds, and by the County of San Diego in the Lower SMR subwatershed. As such, this Appendix will describe monitoring procedures for both agencies.

2 RECEIVING WATER MONITORING PROGRAM

The Receiving Water Monitoring Program is part of a regional effort by the Copermittees to implement a watershed-based monitoring program.

2.1 RECEIVING WATER MONITORING PROGRAM OVERVIEW

Samples will be collected in accordance with the Copermittees' Standard Operating Procedures (SOPs). Monitoring is intended to be compatible with the Surface Water Ambient Monitoring Program (SWAMP). Composite and grab sample times, *in-situ* field measurements, and sampling activities and observations will be recorded on a field data sheet in accordance with the Copermittees' procedures.

The Receiving Water Monitoring Program incorporates the following monitoring components:

- Receiving Water Wet Weather Monitoring and Receiving Water Dry Weather Monitoring (**Sections 2.2** and **2.3**)
- Receiving Water Sampling Teams, Equipment, and Bottles (**Section 2.4**)
- Receiving Water Data Collection (**Section 2.5**)
- Bioassessment Monitoring (**Section 2.6**)
- Hydromodification Monitoring (**Section 2.7**)
- Follow-up Analysis and Actions (**Section 0**)
- Sediment Quality Monitoring (**Section 2.9**)
- Receiving Water Monitoring Program Analysis Types (**Section 2.10**)
- Assessment and Reporting (as discussed in **Chapter 5** of the WQIP)

The Receiving Water Monitoring Program includes both wet weather and dry weather sampling for chemistry and toxicity. The Dry Weather Receiving Water Monitoring Program requires bioassessment monitoring and hydromodification monitoring at least once during the permit term. Refer to **Figure 2-1** for the long-term receiving water monitoring locations.

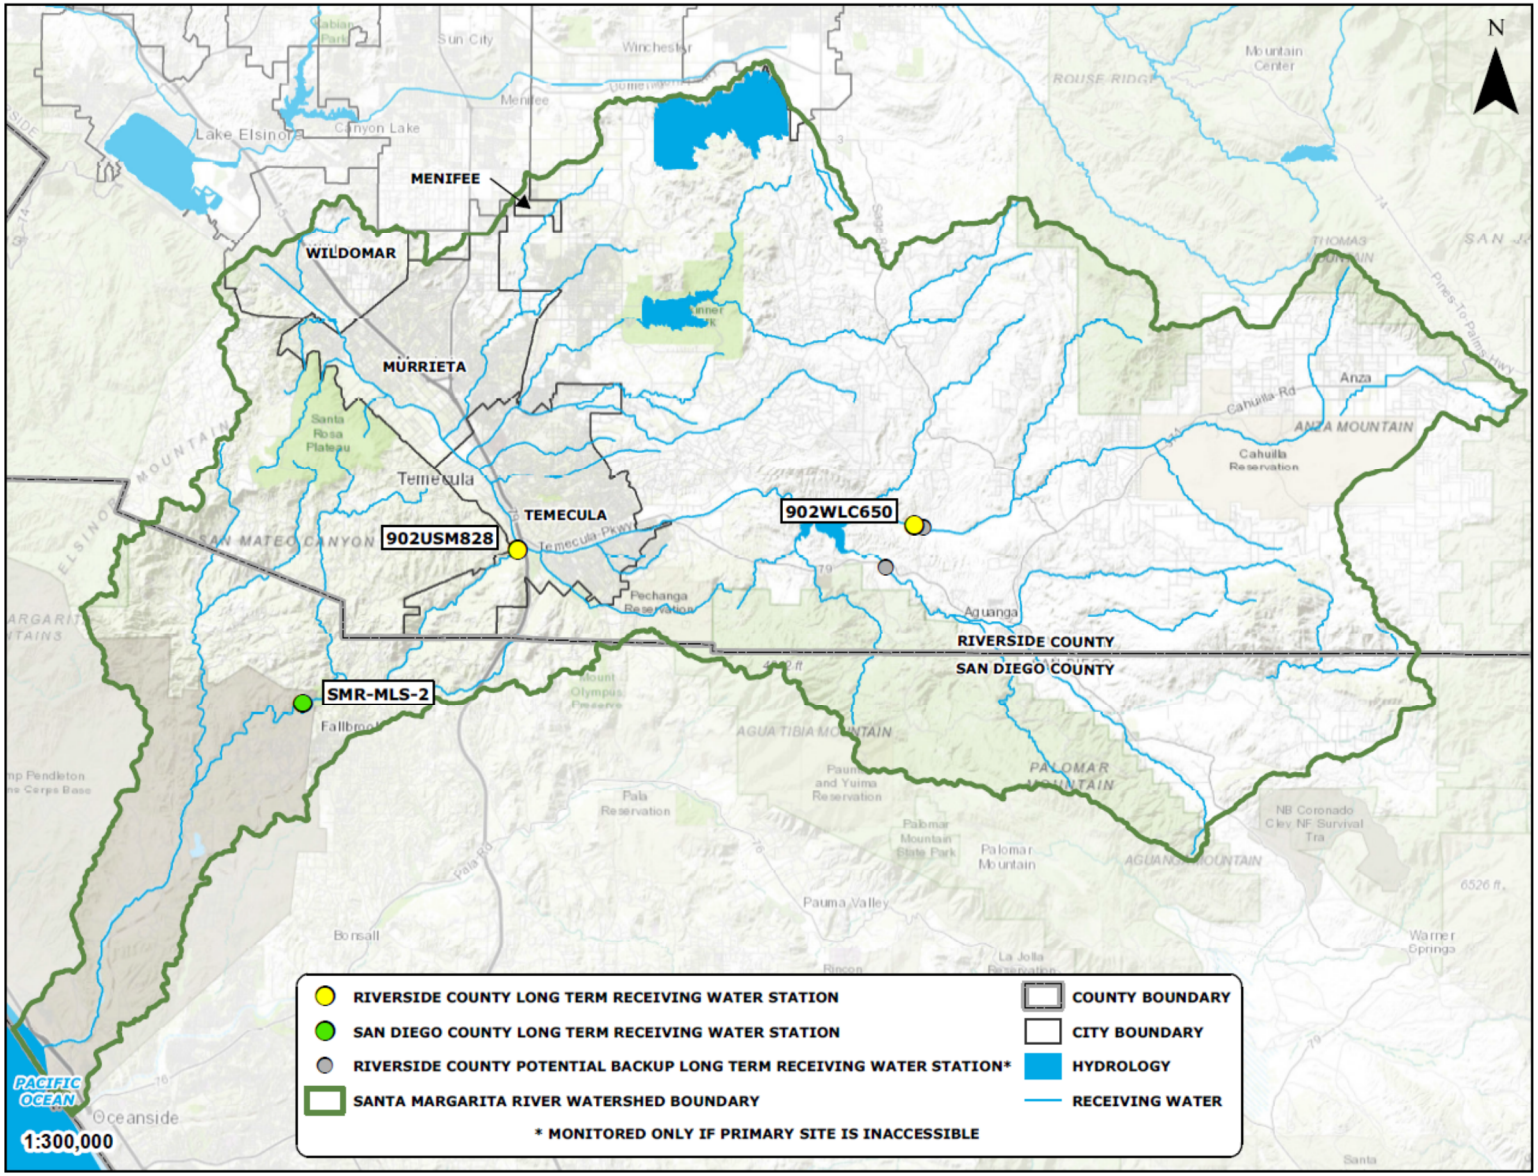

Figure 2-1. WQIP Long-term Receiving Water Monitoring Stations

2.2 RECEIVING WATER WET WEATHER MONITORING

The Permit requires monitoring during three wet weather events at the receiving water monitoring station per permit term. As discussed in **Chapter 5** of the WQIP, all three wet weather monitoring events are scheduled for the 2019-2020 reporting year. In accordance with Provision D.1.d of the Permit, wet weather receiving water monitoring must occur three times during the Permit term. One event must occur during the first wet weather event of the wet season and at least one event must occur during a wet weather event after February 1. In addition to these requirements, one wet weather event will be targeted in the Lower SMR subwatershed as weather patterns dictate, but at least 30 days after the first rainfall event.

Composite and grab samples will be analyzed for the constituents listed in **Section 2.5**. Water quality monitoring at the receiving water monitoring station also includes recording the field observations listed in **Section 2.5**.

The Permit defines the wet season as October 1st through April 30th. Monitoring stations will be sampled according to procedures described in the following **Sections 2.4** and **2.5**.

The following criteria for mobilization will be employed for a wet weather sampling event.

Upper and Middle SMR Subwatersheds Mobilization Criteria

The representative storm event was derived using average rainfall depths and durations from the United States Environmental Protection Agency (USEPA) NPDES Storm Water Sampling Guidance Document, Exhibit 2-8, "Rain Zones of the United States".[1] The derivation is presented in **Appendix 5D**.

- Pursuant to USEPA 833-B-92-001, a representative storm event for the Pacific Southwest is between:
  - 0.27" to 0.81" in depth and
  - within 6 to 18 hours in duration.
- Pursuant to RCFCWCD analysis of local rain gauge data conducted in accordance with USEPA 833-B-92-001, a representative event is between:
  - 0.38" to 1.14" in depth and
  - within 6 to 18 hours in duration.

Due to the ephemeral nature of streams in the SMR, the first storm that falls under the USEPA-recommended criteria may not result in storm induced runoff from tributary areas. Based on the Copermittees' monitoring experience, storm event forecasts of less than 0.5" in 24 hours typically do not result in measureable storm induced runoff and often result in false starts.

Monitoring will be conducted according to the mobilization criteria below for three events during the Permit term:

- If a wet weather event is forecasted by the National Weather Service (NWS) Quantitative Precipitation Statement (QPS) to be greater than 0.1" within the next 48 hours and there is

[1] Exhibit 2-8 "Rain Zones of the United States", Pacific Southwest Region. *NPDES Storm Water Sampling Guidance Document*. U.S. EPA Document No. 833-B-92-001.

at least 72 hours between the forecasted event and a previous measurable (>0.1") rainfall event:

- Then RCFCWCD will follow the procedure outlined in Exhibit 2-7 of USEPA NPDES Storm Water Guidance Document (USEPA 833-B-92-001[2]), included below as **Figure 2-2**, and as discussed in **Appendix 5D**. This decision chart references the speculation of representative storm size.
- Pursuant to NWS standard practice, "Likely" represents a Probability of Precipitation (PoP) of at least 60%.
- Mobilization will occur when the NWS QPS forecast shows likely rainfall of 0.3" in 6 hours AND/OR 0.5" in 24 hours. This gives the Copermittees the greatest chance to sample a representative storm event.
- For mobilization to occur, criteria must be met 24 hours in advance of sampling for coordination with property owners, consultants, and sampling personnel.

Additional information regarding mobilization criteria is available in **Appendix 5D**. Mobilization will occur in accordance with the USEPA Decision Chart for Storm Water Sampling, presented in **Figure 2-2,** and as stated in **Appendix 5D**.

[2] Derived from Exhibit 2-8 "Rain Zones of the United States", Pacific Southwest Region. *NPDES Storm Water Sampling Guidance Document*. U.S. EPA Document No. 833-B-92-001.

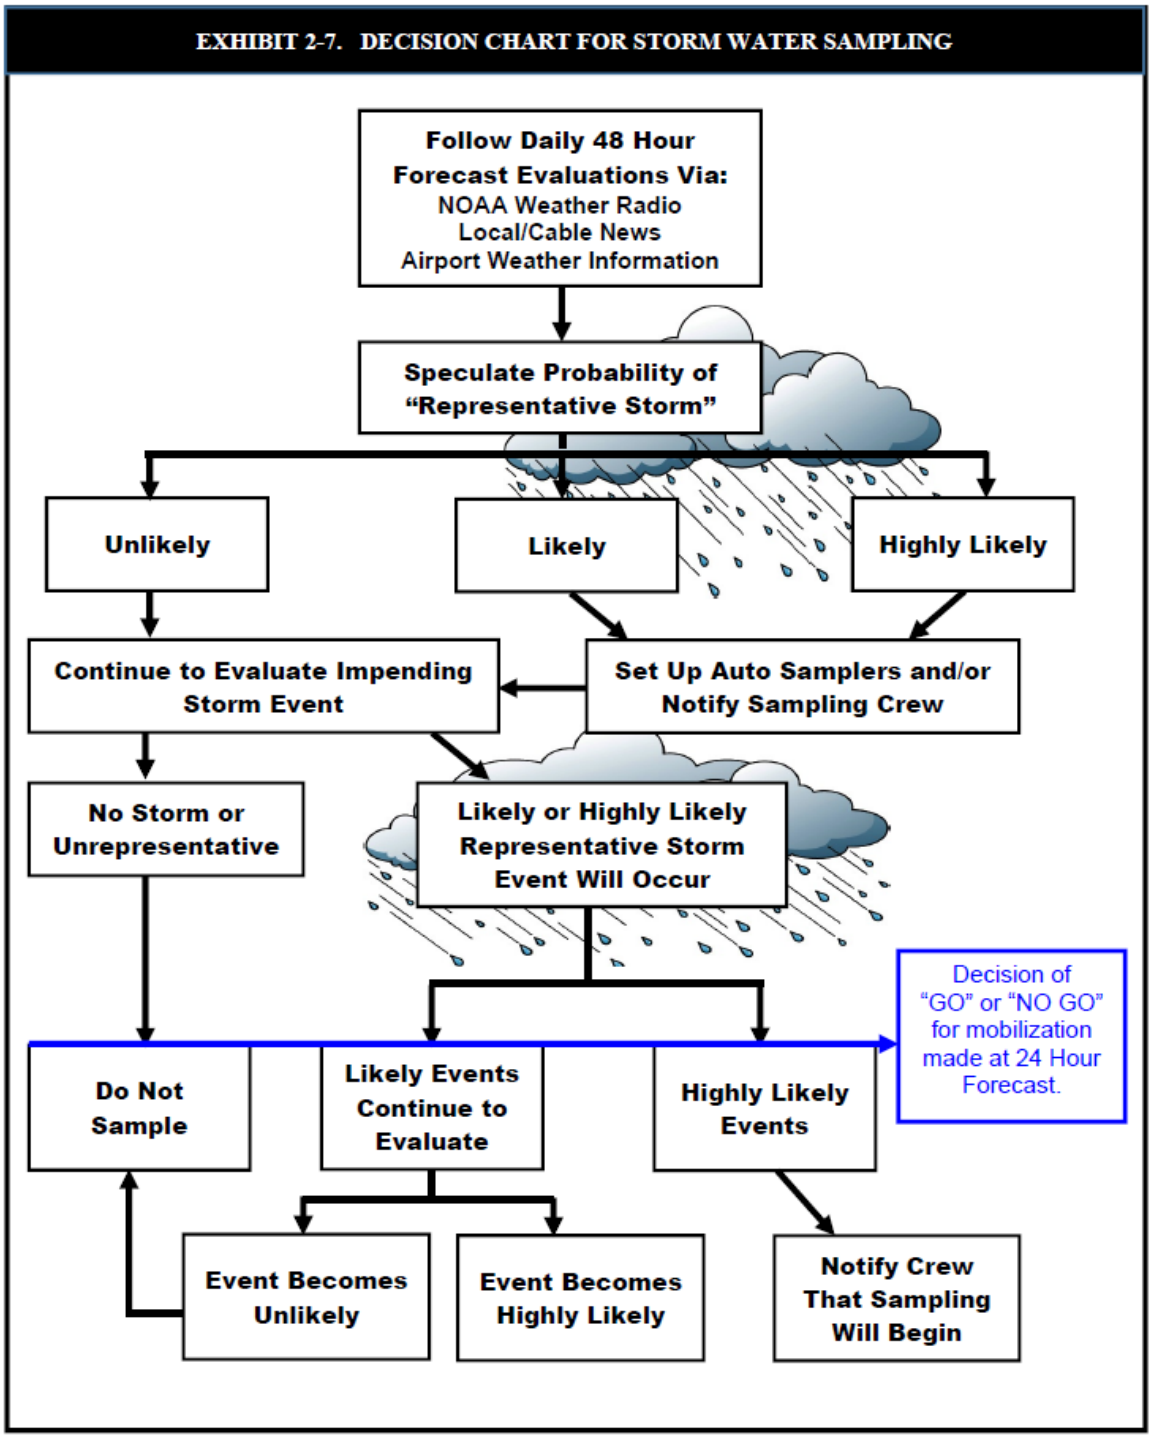

Figure 2-2. USEPA Decision Chart for Storm Event Sampling

Lower SMR Subwatershed Mobilization Criteria

Throughout the wet weather season, field teams will monitor NWS weather reports and data to predict when storms will arrive and to determine whether they will be significant enough to allow monitoring to occur. Storm events will be considered viable for mobilization if they are predicted to produce at least 0.10 inch of rainfall in the drainage area with at least a 70% chance of rainfall.

Each storm of at least 0.1 inch of rainfall must be separated by a minimum of 72 hours. These mobilization criteria must be met at least 24 hours prior to the anticipated onset of rainfall. For the purposes of these criteria, storm forecasts will be obtained from the NWS website (http://www.wrh.noaa.gov/sgx/).

2.3 RECEIVING WATER DRY WEATHER MONITORING

The Permit requires monitoring during three dry weather events at the receiving water monitoring station per permit term. For most constituents, dry weather monitoring will consist of time-weighted composites composed of 24 discrete hourly samples or 24-hour flow-weighted composite samples. Grab samples may be collected for the following constituents during monitoring: pH, temperature, specific conductivity, dissolved oxygen, turbidity, hardness, indicator bacteria, and toxicity. Composite and grab samples will be analyzed for the constituents listed in **Section 2.5**. Water quality monitoring at the receiving water monitoring station also includes recording the field observations listed in **Section 2.5**. Monitoring will be conducted three times during the permit term according to the criteria below, per Provision D.1.c of the Permit:

- At least one monitoring event will occur between May 1st and September 30th. At least one monitoring event will be conducted during a dry weather period during the wet season (October 1 – April 30), after the first wet weather event of the season.
- Dry weather monitoring events will be preceded by an antecedent dry period of at least 72 hours following a storm event producing measurable rainfall of greater than 0.1 inch.

Dry weather monitoring may occur in conjunction with regional monitoring programs, including the SMC Regional Monitoring Program, or special studies. Dry weather receiving water monitoring is scheduled for the 2019-2020 reporting year for the Lower SMR subwatershed, and for the 2020-2021 reporting year for the Upper and Middle SMR subwatersheds. One dry weather event will be targeted in the Lower SMR subwatershed during the month of September 2019, after equipment has been installed and prior to the beginning of the wet season, and one dry weather event will be targeted to occur during a dry weather period after February 1, 2020. Additional information regarding mobilization criteria in the Upper and Middle SMR subwatersheds is available in **Appendix 5D**.

2.4 RECEIVING WATER SAMPLING TEAMS, EQUIPMENT, AND BOTTLES

Sampling Teams

Monitoring teams will be comprised of two Copermittee field personnel and/or consultants. All field personnel will have current and relevant experience in all aspects of standard field monitoring, including use of relevant field equipment such as field instruments and monitoring equipment. Field personnel will be trained and have experience in the collection, handling/storage, and chain-of-custody procedures.

All samples will be delivered to the laboratory by field crews promptly following sample collection. Runners will be used as necessary to ensure samples are delivered to the laboratory within USEPA recommended holding times.

Equipment

For most constituents, wet weather monitoring will consist of flow-weighted composite samples collected over the length of the entire storm or 24-hours whichever comes first. Grab samples will

be collected for the following constituents during wet weather monitoring: pH, temperature, specific conductivity, dissolved oxygen, turbidity, hardness, salinity, and indicator bacteria. If site/monitoring conditions change, Copermittees may elect to collect toxicity via a grab sample as well. Monitoring equipment may include:

- Data-logging flow meter
- Automated composite sampler with sample tubing
- Tipping bucket rain gauge
- 12-V DC power supply
- Data telemetry unit (as necessary and/or available)
- Portable field water quality meter(s)
- Wet weather gear for wet weather events
- Ice
- Field books with field data sheets, site maps, hospital routes, sampling procedures, equipment manuals and chains of custody
- Sample bottles
- A toolbox with tools such as nitrile gloves, headlamps, zip ties, diagonal cutters, adjustable wrenches, and screwdrivers to take samples and make adjustments as needed on equipment during the storm event
- Extra autosampler bottles to make bottle changes as needed
- A cellphone to maintain communication lines with the project manager and field lead.

Installation and Maintenance

Prior to the start of each wet weather event, the electronic equipment and clean tubing will be installed at the receiving water monitoring stations in preparation for the anticipated wet weather event. Upon completion of monitoring, the equipment will be removed from the site and stored at either the Copermittee's or consultant's office. Monitoring equipment at the receiving water monitoring station may be installed during the beginning of individual dry weather monitoring events**.** Maintenance and calibration will be performed prior to monitoring each receiving water monitoring event according to the manufacturer's specifications.

A second set of equipment may be set up at the receiving water monitoring stations to collect enough volume for required toxicity analyses. The receiving water monitoring station may be equipped with eight 1-gallon bottles or two 19-liter bottles using the same protocols as above for the collection of automated composite toxicity samples. Automated equipment is recommended but not required for composite sampling.

Bottles

Composite samples may be collected directly into 19-liter bottles or into individual 1-gallon bottles that will be composited at the laboratory. Grab samples may be collected by manually operating the automated equipment to fill the appropriate bottles or by following grab sampling protocols described in **Appendix 5D** for the Upper and Middle SMR subwatersheds and **Section 2.5** for the Lower SMR subwatershed. **Appendix 5D** contains additional information regarding sample

bottles for the Upper and Middle SMR subwatersheds, and **Section 2.5** contains additional information regarding sample bottles for the Lower SMR subwatershed. **Table 2-1** provides a summary of bottles required for receiving water monitoring.

Table 2-1. Receiving Water Monitoring Bottle List

Constituent	Container Type Per Site[(1)]	Preservative	USEPA Recommended Holding Time
E. coli, Fecal Coliform, Total Coliform, *Enterococcus*	2 x 125-mL plastic (each)	$Na_2S_2O_3$	8 hours
Toxicity	7 x 1-Gallon amber glass (1 additional grab if TIE required) or 2 x 19-Liter bottle	≤6°C	48 hours
All other constituents (Chemistry)	1 x 19-Liter glass (& 1 spare 19-L glass) or 3 x 1-Gallon glass or As directed by the laboratory	≤6°C	48 hours (minimum)

1. Container Type and size may vary based on equivalent recommended by ELAP certified laboratory.

2.5 RECEIVING WATER DATA COLLECTION

The following samples and measurements will be collected at the receiving water monitoring station:

- Composite Samples
  - Chemistry time or flow weighted composite samples
  - Toxicity time or flow-weighted composite samples
- Grab samples
  - Toxicity grab samples (if composite samples are not collected)
  - Bacteriological grab samples
  - Hardness (if composite sample is not collected)
- *In-situ* field measurements
  - Temperature
  - pH
  - Specific conductivity
  - Dissolved oxygen
  - Turbidity
  - Salinity

- Wet Weather Field Observations
    - A narrative description of the station that includes the location, date and duration of the storm event(s) sampled, rainfall estimates of the storm event, and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event; and
    - The flow rates and volumes measured or estimated (data from nearby USGS gauging stations may be utilized, or flow rates may be measured or estimated).
- Dry Weather Field Observations
    - Station identification and location
    - Presence of flow, or pooled or ponded water
    - If flow is present:
        - Flow estimation (i.e. width of water surface, approximate depth of water, approximate flow velocity, flow rate)
        - Flow characteristics (i.e. presence of floatables, surface scum, sheens, odor, color)
    - If pooled or ponded water is present:
        - Characteristics of pooled or ponded water (i.e. presence of floatables, surface scum, sheens, odor, color)
    - Station description (i.e. deposits or stains, vegetation condition, structural condition, and observable biology)
    - Presence and assessment of trash in and around station

Constituents for analysis are available in **Table 2-2**.

Table 2-2. Receiving Water Constituents for Analysis

Analyte Group	Constituents
Conventionals, Nutrients	Chlorophyll-a[1,2], Total Dissolved Solids, Total Suspended Solids, Total Hardness, Total Organic Carbon, Dissolved Organic Carbon, Sulfate, Methylene Blue Active Substances (MBAS), Total Phosphorus, Orthophosphate, Total Phosphate (calc.), Nitrite[3], Nitrate[3], Total Nitrogen (calc.), Total Kjeldhal Nitrogen, Ammonia
Metals (Total and Dissolved)	Aluminum, Arsenic, Cadmium, Chromium, Chromium III[1], Chromium VI[1], Copper, Iron, Lead, Manganese, Mercury, Nickel, Selenium, Silver[1], Thallium, Zinc
Pesticides	Organophosphate Pesticides, Pyrethroid Pesticides
Indicator Bacteria	Total Coliform, Fecal Coliform, *Enterococcus*, *E. Coli*
Toxicity[4]	*Pimephales promelas* (Fathead Minnow), *Ceriodaphnia dubia* (Daphnid), *Selenastrum capricornutum* (Green Algae), Strongylocentrotus purpuratus (Purple Sea Urchin)

1. Only collected during dry weather monitoring events.
2. Collected as part of Bioassessment monitoring.
3. Nitrate and nitrite may be combined and reported as nitrite + nitrate
4. If sample has salinity less than 1ppt, then test for *Pimephales promelas*, *Ceriodaphnia dubia*, *Selenastrum capricornutum*. If sample has salinity greater than 1ppt, then test for *Strongylocentrotus purpuratus*. To determine the most sensitive test species for freshwater, all three test species will be screened for two wet weather events. After this screening period, toxicity monitoring will only be conducted using the most sensitive test species. Rescreening will occur once each permit term.

Detailed sampling methods are available in **Appendix 5D** for the Upper and Middle SMR subwatersheds. The following describes specific procedures used in the Lower SMR subwatershed for receiving water data collection:

Field measurements will be performed for pH, specific conductance, temperature, DO, and turbidity using a YSI data sonde or similar device. Calibration of the instruments will be conducted prior to each sampling event according to the manufacturer's specifications and calibrated following each sampling event. Calibration records will be kept on file.

Grab samples will be collected from the horizontal and vertical center of the channel if possible and kept clear from uncharacteristic floating debris. Because oil and grease and other petroleum hydrocarbons tend to float, oil and grease grab samples will be collected at the air–water interface. Microbiology samples will be collected using sterile techniques. Nitrile or latex type gloves will be worn during sample handling. During the sample event, a 100-milliliter (mL) sterile bacteria bottle will be used to collect the sample directly from the receiving water or using a bucket. Care will be employed to not allow contact with area structures or the bottom sediments. The container will be opened only for the needed time to collect the sample and will be closed immediately following sample collection. If it is suspected that the container was compromised at any time, the sample container will be discarded, and a new sample will be collected with a new sample bottle. The sample must be filled only to the 100-mL mark on the sample bottle (not over topped or under filled).

A single flow-weighted composite sample will be collected during the dry weather and wet weather monitoring events. During the monitoring event, sample aliquots will be collected in proportion to the rate of flow (i.e., flow-weighted) using automated equipment and Teflon-lined tubing. Dry weather flow-weighted composite samples will be collected over a typical 24-hour period. Wet weather flow-weighted composite samples will be collected by taking sample aliquots across the hydrograph of the storm event. Based on the anticipated size of the storm, a flow-proportioned pacing will be programmed into the automated sampling equipment. The first sample aliquot will be taken at or shortly after the time that stormwater runoff begins, and each subsequent aliquot of equal volume will be collected every time the pre-selected flow volume (flow-proportional pacing) discharges past the monitoring station. Some variation may occur depending on actual storm intensity and duration.

Flow-weighted water samples will be collected in pre-cleaned 20-liter (L) borosilicate graduated glass bottles. Sample bottles will be properly labeled with sample ID, date, and time; sealed with a pre-cleaned rubber stopper; and preserved on ice for transport. Approximately 19 L of sample water will be contained in a "full" bottle. If flow rate sampling adjustments are made during a sampling event, the volume of sample to be used in sample compositing will differ among the various bottles from a given station to ensure the final composite sample is properly flow-weighted. To ensure a representative sample is used, samples should be agitated and mixed prior to pouring out any liquid. A 1000-mL glass graduated cylinder will be used to measure any sample volume that will be composited if it is less than the full amount contained within a 19-L sample bottle. The mixing will be done between transfers of liquid. Samples will be agitated continuously using a pre-cleaned glass stir bar as they are poured into the large pre-cleaned Nalgene containers. After all of the samples from a specific station have been added to the compositing container, subsampling may begin. Subsamples for chemical analyses will be poured into glass containers with Teflon® lids.

2.6 RECEIVING WATER BIOASSESSMENT MONITORING

2.6.1 Receiving Water Bioassessment Monitoring Mobilization Criteria

Receiving water bioassessment monitoring will be conducted once per permit term according to the criteria below:

- Bioassessment monitoring must be preceded by at least 72 hours of dry conditions (<0.1 inch of precipitation).[3]
- Bioassessment monitoring may occur in conjunction with receiving water dry weather monitoring, and may be conducted in coordination with special studies or regional monitoring programs, such as the SMC Regional Monitoring Program, when feasible.
- Bioassessment monitoring will be conducted during the spring/summer dry season bioassessment index period, typically from April through July in Southern California.

2.6.2 Receiving Water Bioassessment Sampling Teams and Bottles

Sampling Teams

Bioassessment teams must be led by a person specifically trained in bioassessment techniques. One team comprised of two or more Copermittee field personnel (and/or consultant field personnel) will monitor each receiving water monitoring station once per permit term. Additional monitoring teams may be coordinated based on participation of the SMC Regional Monitoring Program and/or other regional monitoring programs.

All samples will be delivered to the laboratory by field crews promptly following sample collection. Runners will be used as necessary to ensure samples are delivered to the laboratory within USEPA recommended holding times.

Installation and Maintenance

For recommended chemistry samples, equipment at bioassessment monitoring stations may be installed during the beginning of individual dry weather monitoring events. Maintenance and calibration will be performed prior to monitoring each dry weather event.

Automated equipment is recommended but not required for composite sampling.

Bottles

Bioassessments and algae collection require a specific set of bottles as needed by the contracted laboratory. Qualified staff will be utilized for this specialized effort.

2.6.3 Receiving Water Bioassessment Data Collection

Bioassessment monitoring will occur once per permit term at the receiving water monitoring station. The following types of samples and measurements will be collected:

- Bioassessment

[3] Bioassessment monitoring will not be conducted in the Upper SMR and Middle SMR subwatersheds for the four weeks that follow a scouring rain event that disrupts the benthic communities. Bioassessment monitoring will not be conducted in the Lower SMR subwatershed within a two to three week period after any significant rainfall event that would initiate scouring of bed material.

- CSCI measurements for benthic macroinvertebrates
- Physical habitat characterization[4]
- Algal taxonomic composition and algal biomass
- CSCI measurements for benthic algae

- *In-situ* field measurements (covered under **Section 2.5**)
  - Temperature
  - pH
  - Specific conductivity
  - Salinity
  - Alkalinity (if not analyzed in the laboratory)
  - Dissolved Oxygen
  - Turbidity (if not analyzed in the laboratory)
- Aqueous chemistry data will be collected in the Upper SMR and Middle SMR subwatersheds in coordination with bioassessment monitoring (covered under **Section 2.5**). The full list of constituents for analysis are listed in **Table 2-2.**

Detailed bioassessment sampling procedures are available in SOPs for the Collection of Field Data for Bioassessments of California Wadeable Streams: Benthic Macroinvertebrates, Algae, and Physical Habitat (SWAMP SOP) (Ode, Fetcher, Busse, 2016).

Refer to **Section 5** for required data records and COC information.

2.7 HYDROMODIFICATION MONITORING

2.7.1 Hydromodification Management Plan Monitoring

Hydromodification Management Plan (HMP) Monitoring will be conducted annually at two stations in the Middle SMR Watershed, through spring of 2019 as specified in Appendix K of the 2016 SMR HMP. Refer to **Figure 2-3** below for respective Hydromodification monitoring locations. HMP Monitoring will be conducted in the spring (April –June) and must be preceded by at least 72 hours of dry conditions. Hydromodification monitoring as specified in the 2011 Regional HMP for the County of San Diego did not include any monitoring sites in the SMR WMA.

2.7.2 Dry Weather Receiving Water Hydromodification Monitoring

Dry Weather Receiving Water Hydromodification Monitoring will occur once per permit term at each long-term receiving water monitoring station identified in Section 5.3.1.1 of the WQIP. Refer to **Figure 2-3** below for respective hydromodification monitoring locations. Hydromodification monitoring will occur in conjunction with receiving water dry weather monitoring, and may be conducted in coordination with special studies and regional monitoring programs, such as the SMC

[4] The "Full" suite of physical habitat characterization measurements will be collected in accordance with the SWAMP Stream Habitat Characterization Form – Full Version: http://www.waterboards.ca.gov/water_issues/programs/swamp/docs/reports/fieldforms_fullversion052908.pdf

Regional Monitoring Program, when feasible. Dry Weather Receiving Water Hydromodification Monitoring must be preceded by at least 72 hours of dry conditions (<0.1 inch of precipitation).

In general, dry weather hydromodification monitoring conducted at the long-term receiving water stations within the WMA will coincide with a dry weather monitoring event scheduled in the spring, likely in May or June, as well as the dry weather receiving water bioassessment monitoring effort. Additional information regarding mobilization criteria for the Upper SMR and the Middle SMR subwatersheds is available in **Appendix 5D.**

2.7.3 Receiving Water Hydromodification Sampling Teams and Equipment

Sampling Teams

Monitoring teams will be comprised of two Copermittee field personnel (and/or consultant field personnel). Additional monitoring teams may be coordinated based on participation of the SMC Regional Monitoring Program and/or other regional monitoring programs.

Equipment

The following equipment may be utilized for hydromodification monitoring:

- Camera
- Stadia rod
- Gravity-driven protractor
- Measuring tape
- Sight level

2.7.4 Receiving Water Hydromodification Data Collection

The following types of observations and measurements will be collected:

- Channel conditions, including
  - Channel dimensions
  - Hydrologic and geomorphic conditions
  - Presence and condition of vegetation and habitat
- Location of discharge points
- Habitat integrity
- Photo documentation of existing erosion and habitat impacts, with latitude and longitude coordinates of where photos were taken
- Measurement or estimate of dimensions of any existing channel bed or bank eroded areas, including length, width, and depth of any incisions
- Known or suspected cause(s) of existing downstream erosion or habitat impact, including flow, soil, slope, and vegetation conditions, as well as upstream land uses and contributing new and existing development

Refer to **Section 5** for required data records and COC information.

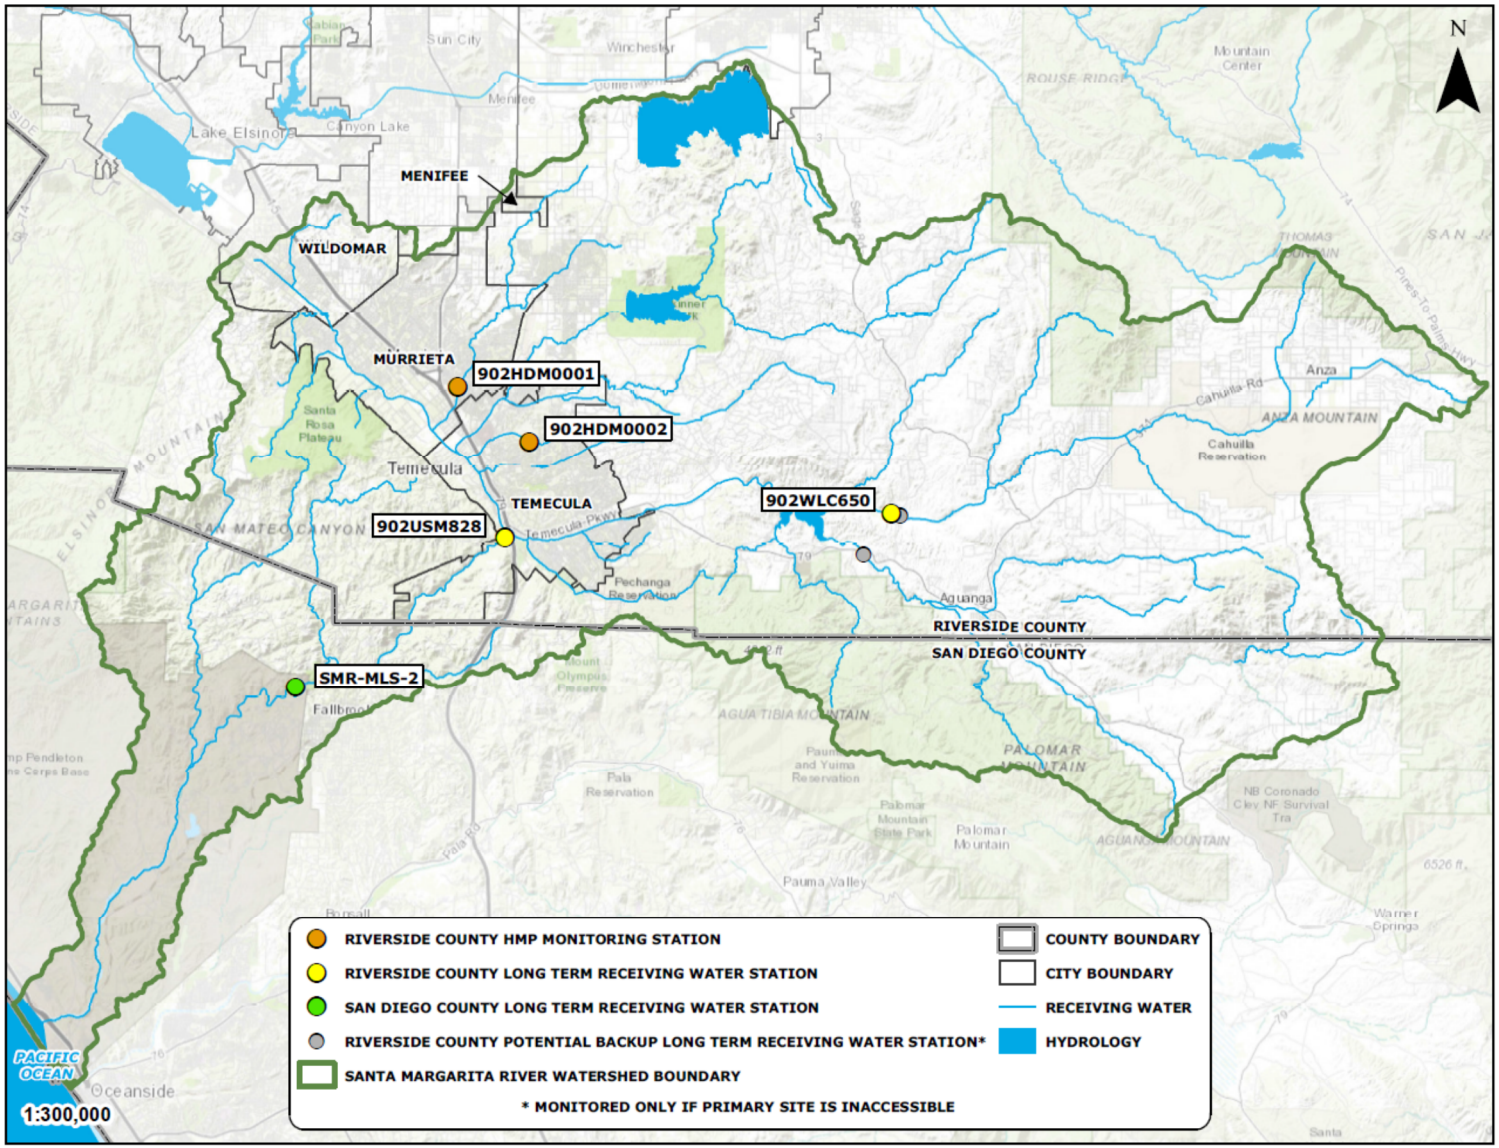

Figure 2-3. Hydromodification Monitoring Locations

2.8 FOLLOW-UP ANALYSIS AND ACTIONS

The results from the Receiving Water Monitoring Program including wet weather, dry weather, bioassessment, and hydromodification monitoring will be assessed after each monitoring event as soon as results are available and have been reviewed for quality. When chronic toxicity is detected in receiving waters, the Copermittees will discuss the need for conducting a TIE/TRE in the assessments detailed in **Chapter 5** of the WQIP. A work plan that outlines the process undertaken in the Lower SMR subwatershed to identify chronic toxicity and prioritize the need to implement TIEs/TREs based on the magnitude and persistence of chronic toxicity is included as **Appendix 5E.** A plan for implementing the TIE/TRE will be developed for the Upper SMR and Middle subwatersheds will be incorporated herein when determined by the Copermittees that one is needed.

2.9 SEDIMENT QUALITY MONITORING

Sediment quality monitoring will be conducted in the Santa Margarita Estuary in compliance with the State Water Resources Control Board's Water Quality Control Plan for Enclosed Bays and Estuaries of California – Part 1 Sediment Quality (Sediment Control Plan). The sediment quality monitoring requirements of the Permit will be fulfilled by participation in the Bight '18 Program and any necessary follow-up monitoring.

The Bight Program, which is overseen by SCCWRP, focuses on water quality, coastal ecology, sediment quality, and shoreline microbiology. Participation in the Bight Program can be used to simultaneously fulfill all or part of the sediment quality monitoring requirements of Provision D.1.e.(2) because sediment monitoring and sediment quality objectives (SQO) analyses are incorporated into the Bight Program to regionally assess the sediment quality of Southern California's enclosed bays, lagoons, and estuaries (herein referred to as waterbodies), including those waterbodies in San Diego County. Copermittees may also decide to conduct the initial sediment quality monitoring of San Diego County's water bodies independently of the Bight Program. Depending upon the outcome of the initial SQO assessments, follow-up monitoring may need to be performed to meet all of the Permit requirements.

The primary objective of the sediment monitoring program is to assess compliance with the sediment quality receiving water limits applicable to MS4 outfall discharges to enclosed bays and estuaries of San Diego County. Sediment toxicity, chemistry, and benthic community condition will be assessed using SQOs. The goals of the SQOs are to determine whether pollutants in sediments are present in quantities that are toxic to benthic organisms and/or will bioaccumulate in marine organisms to levels that may be harmful.

Analyses of chemistry, toxicity, and benthic community condition require that samples be collected, preserved, processed, and analyzed using proper field and laboratory equipment, methods, and techniques. Additionally, the selection of representative station locations is necessary to ensure proper characterization of benthic conditions. The Sediment Monitoring Plan and Sediment Monitoring Quality Assurance Project Plan (QAPP) (**Appendix 5F**) describe the collection and analysis of surface sediment samples necessary to provide representative assessments of in situ conditions for the enclosed bays and estuaries of San Diego County.

2.9.1 Sediment Sampling and Handling

Benthic sediments will be collected as surface grabs using an appropriate sampler, such as a 0.1 square meter (m^2) stainless steel Van Veen grab sampler. Sediment grabs will be collected for the following analyses: benthic infauna, chemistry, grain size, and toxicity. The entire contents of one grab sample will be utilized for benthic community analyses with a minimum penetration depth of 7 cm. Sediment samples for chemistry and toxicity testing will be collected from the top 5 cm of a grab sample using a pre-cleaned stainless steel scoop. Station location and grab event data will be recorded on field data sheets and will include the following information: station identification, station location, date, time of sample collection, depth of water, depth of penetration of grab in sediment (e.g. 5 cm), sediment composition, sediment odor and color, and sample type (e.g. sediment chemistry). It is recommended that photographs of each sediment sample be taken and stored.

All sampling equipment will be cleaned prior to sampling. Between sampling stations, the grab sampler will be rinsed with station water. Stainless steel scoops will be rinsed with seawater and rinsed with de-ionized water between stations. All sediment samples will be logged on a chain-of-custody (COC) form. Sediment chemistry and toxicity samples will be placed in a cooler on ice until delivered or shipped to the appropriate laboratories. Prior to shipping, sample containers will be placed in sealable plastic bags and securely packed inside the cooler with ice. The original signed COC forms will remain with the samples during shipment. Sediment samples will be shipped or delivered to the analytical laboratory within appropriate holding times.

2.9.2 Physical and Chemical Analysis

Physical and chemical measurements of sediment were selected to comply with the Sediment Control Plan and to provide data on chemicals of potential concern in bays and estuaries located in San Diego County. In accordance with the Sediment Control Plan, the physical and chemical analyses of sediments will include, at a minimum, the constituents outlined in polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) shown in **Table 2-3**. If sediment quality monitoring is conducted as part of the Bight Program, additional chemical analyses may be included and will be provided in Bight Workplans. Reporting limits (RLs) must be equal to or less than those listed in polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) shown in **Table 2-3**. Concentrations associated with the RLs in polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) shown in **Table 2-3** are expressed in dry-weight. Physical analyses of sediment will include grain size and percent solids. Grain size will be analyzed to determine the general size classes that make up the sediment (e.g., gravel, sand, silt, and clay), whereas percent solids will be measured to convert chemical concentrations from a wet-weight to a dry-weight basis. Chemical analyses of sediment will include total organic carbon (TOC), and the select trace metals, chlorinated pesticides, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) shown in **Table 2-3**.

Table 2-3. Sediment Quality Parameters

Parameter	Reporting Limit
Physical/Conventional Tests	
Grain Size	1.00 %
Percent Solids	0.10 %
Total Organic Carbon (TOC)	0.01 %

Parameter	Reporting Limit
Metals	
Cadmium (Cd)	0.09 mg/kg
Copper (Cu)	52.8 mg/kg
Lead (Pb)	25.0 mg/kg
Mercury (Hg)	0.09 mg/kg
Zinc (Zn)	60.0 mg/kg
Organochlorine Pesticides	
2,4′-DDD	0.50 µg/kg
2,4′-DDE	0.50 µg/kg
2,4′-DDT	0.50 µg/kg
4,4′-DDD	0.50 µg/kg
4,4′-DDE	0.50 µg/kg
4,4′-DDT	0.50 µg/kg

2.9.3 Toxicity Testing

To evaluate the benthic condition of San Diego County's waterbodies, sediment toxicity testing will be conducted in accordance with American Society for Testing and Materials (ASTM) and USEPA methods. Toxicity testing involves a short-term survival test, a sublethal endpoint test, and an assessment of sediment toxicity. For each test type, more than one specific test is acceptable. The appropriate species tested for a sample will depend on the characteristics of the sample such as grain size, salinity, and suspected toxic constituents, if any. When historical data are available for a sample location, it is recommended that the same species be used in order to make comparisons and to conduct trend analysis. In addition, if sediment monitoring is conducted as part of the Bight Program, the species selection will be listed in the Bight Workplans. If significant toxicity is observed in the solid phase or sediment-water interface test, a TIE may be conducted. Further descriptions of the test species used in both the short-term survival test and the sublethal endpoint test are provided in the Sediment Monitoring Plan. The test species used in previous San Diego County bay and lagoon monitoring programs have consisted of the marine amphipod *Eohaustorius estuarius*, the marine bivalve *Mytilus galloprovincialis,* and the marine polychaete *Neanthes arenaceodentata*.

2.9.4 Benthic Infauna Analysis

The benthic infaunal samples will be transported from the field to the laboratory and stored in a formalin solution for a minimum of 48 hours and no longer than 5 days. The samples will then be transferred from formalin to 70% ethanol for laboratory processing. The organisms will initially be sorted using a dissecting microscope into five major phyletic groups: polychaetes, crustaceans, molluscs, echinoderms, and miscellaneous minor phyla. While sorting, technicians will keep a count for quality control purposes, as described in the following paragraph. After initial sorting, samples will be distributed to qualified taxonomists who will identify each organism to species or to the lowest possible taxon. Taxonomists will use the most recent version of the Southern California Association of Marine Invertebrate Taxonomists (SCAMIT) taxonomic listing for nomenclature and orthography. Since sediment monitoring is conducted as part of the Bight Program, procedures should be in accordance with Bight Workplans.

2.10 RECEIVING WATER MONITORING PROGRAM ANALYSES TYPES

Grab and composite samples collected under the Receiving Water Monitoring Program (wet weather, dry weather, and bioassessment) will be analyzed for the constituents listed in **Sections 2.4** through **2.6**. The volume required, methods, target Reporting Limits (RLs), units, and holding times for all constituents to be monitored within the receiving water are identified in **Appendix 5D** for the Upper SMR and Middle SMR subwatersheds and **Table 2-4** for the Lower SMR subwatershed. Grab samples may be collected for pH, temperature, specific conductivity, salinity, alkalinity, dissolved oxygen, turbidity, hardness, and indicator bacteria. All other constituents will be collected as composite samples (with the potential exception of toxicity) based on program type described in **Sections 2.4** through **2.6**.

Table 2-4. Sample Volume, Analytical Methods, Project RLs, Units, and Holding Time Requirements for Analysis of Water Samples (Lower SMR Subwatershed)

Constituent	Volume Required	Method	Target Reporting Limit	Units	Max Holding Time
pH	In field	Meter	0.01	pH	N/A
Temperature	In field	Meter	0.1	° Celsius	N/A
Specific Conductance	In field	Meter	1	µS/cm	N/A
Dissolved Oxygen	In field	Meter	0.01	mg/L	N/A
Turbidity	In field	Meter	0.1	NTU	N/A
Chlorophyll-a[1]		SM 10200 H-2b	10 mg/m^2	mg/m^2	Freeze in 4H; Analyze in 28D
Total Dissolved Solids	500 mL	SM 2540C	10	mg/L	7D
Total Suspended Solids	1000 mL	SM 2540D	5.0	mg/L	7D
Total hardness	Calculated from Calcium and Magnesium	SM 2340B	0.662	mg/L	N/A

Growth with *Selenastrum capricornutum*	4L	EPA-821-R-02-013	N/A	Pass/Fail	36hr

1. Collected and analyzed in conjunction with the Bioassessment monitoring.
2. 7 days for sample extraction and 40 days holding for extract to be analyzed.

2.10.1 Chemistry and Toxicity Composite Samples

Chemistry and toxicity composite samples will be time-weighted or flow-weighted composites comprised of a series of sample aliquots. Time-weighted sample aliquots will be collected at predetermined intervals over the duration of the monitoring period. Flow-weighted sample aliquots will be collected according to a sample pacing which will be determined based on the amount of flow anticipated to occur during the monitoring event. Samples may be composited at the laboratory. Further detail regarding standard flow-weighted and time-weighted composite sampling is provided in **Appendix 5D**.

The toxicity tests will be conducted on the cladoceran *Ceriodaphnia dubia*, the freshwater minnow *Pimephales promelas,* and the freshwater plant *Selenastrum capricornutum* if sample salinity is less than (<) 1 part per thousand (ppt). If sample salinity is greater than or equal to (≥) 1 ppt, the purple sea urchin *Strongylocentrotus purpuratus* will be used for toxicity testing. Toxicity data collected under the long-term monitoring requirements of the Permit will be analyzed using the Test of Significant Toxicity (TST) (USEPA, 2010) and given a Pass or Fail assessment. In accordance with Permit Provision D.1.c.4.f, a Toxicity Identification Evaluation (TIE) or Toxicity Reduction Evaluation (TRE) may be required if significant toxicity is repeatedly observed in a sample and the cause has not been previously investigated.

2.10.2 Grab Samples

Grab samples may be collected for the constituents previously identified in **Section 2.4** through **2.6**. If flows are too shallow to submerge the sample container directly, a secondary, pre-cleaned, sample vessel may be used to transfer sample water into the sample containers. Receiving water grab samples will be collected using protocols outlined in **Appendix 5D**. Grab samples should be collected and delivered to the laboratory in accordance with **Sections 2.4** through **2.6**.

Grab samples will not be collected if flow and/or depth are found to be insufficient. Depth at sample point must be sufficient to collect sample via submerging the collection container/scoop without disturbing substrate along bottom of stream or channel bed. Flow at sample point must be sufficient to observe surface velocity (unless ponded samples are required).

2.10.3 *In-situ* Field Measurements

In-situ water quality field measurements will be collected at each receiving water station once during each monitoring event. *In-situ* field measurements will be collected concurrently with grab sample collection.

Standard procedures for collecting *in-situ* water quality parameters are described in **Appendix 5D**. If meter failure occurs, the field team will attempt to use a back-up meter or another team's meter. As a last resort, the laboratory will be instructed to analyze for any missing parameters according to the methods provided in **Appendix 5D**.

2.10.4 Flow and Precipitation Monitoring

During wet weather monitoring, flow and precipitation data will be recorded throughout the monitoring event, when possible. Flow and precipitation monitoring will commence during the pre-event preparation and will terminate upon completion of sampling.

Additional flow measurement information for the Upper SMR and Middle SMR subwatersheds is presented below:

Flow meters will be programmed to record stage (to be converted to flow values based on channel dimensions). Where automated equipment is not used, flow will be estimated by collecting the following measurements:

- Width of the water surface,
- Approximate depth of the water, and
- Approximate flow velocity.

Alternatively, visual estimates may be made per the procedures detailed in **Appendix 5D**. Ponded water will be indicated by 0.0 cubic feet per second (cfs). No flow or no discharge will be indicated by "DRY" and 0.0 cfs.

Additional flow measurement information for the Lower SMR subwatershed is presented below:

Flow rates will be monitored using American Sigma (or comparable) flowmeters with an area-velocity sensor, ultrasonic sensor, bubbler, or submerged pressure transducer as the primary measuring device. The primary sensor will continuously measure stage and relay that information to the flowmeter. The flowmeter will continually calculate flow rates by inserting the stage information into the preprogrammed discharge equation. Using this system, the flowmeter will be able to actuate the sampler to achieve a flow-weighted composite sample. Sampling and flow equipment will be monitored remotely, and data will be transferred to a permanent data system by cellular modem or manual download.

The mass loading station (MLS) equipment installed and used for monitoring during dry weather will remain in place during the course of the monitoring year (except where stations are located specifically for dry weather only sampling). The MLS monitoring period is approximately September 1 through June 30. Continual flow data will be downloaded remotely from the station once every two weeks to verify equipment functionality, reduce data gaps, ensure accuracy, and identify maintenance and calibration needs. Flow data will be entered into the data management system. Equipment will be maintained throughout the year to ensure it is in proper working order.

Stream Ratings

The flow rate at the monitoring station will be determined by stream stage sensors that are typically secured to the bottom of the channel. To quantify flow rates based on stream stage, a relationship between flow and stage will be derived using the standardized stream rating protocols developed by the U.S. Geological Survey (USGS) (Rantz, 1982; Oberg et al., 2005). Instantaneous flow

measurements will be taken at various stages. The measurements will be combined to produce and calibrate the rating curve for the station.

To accurately measure flow in streams, the following three critical elements are needed to develop the rating curves:

- An accurate survey of the stream channel cross section and longitudinal slope.
- Accurate level measurements based on a fixed point.
- Measurements of velocity and flows at several points throughout the rating curve, including low flow, mid flow, and peak flow conditions.

To measure instantaneous flows during low flow and base flow conditions, two velocity measurement instruments are typically used—a Marsh-McBirney Model 2000 Portable Flowmeter connected by a cable to an electromagnetic open channel velocity sensor and the SonTek (YSI) FlowTracker Acoustic Doppler Velocimeter. The FlowTracker is a high-precision, shallow-water flowmeter that measures velocity in three dimensions and features an automatic discharge computation.

To make an instantaneous flow measurement, a tape measure is stretched across the stream, perpendicular to flow and secured on both banks of the stream. The tape is positioned so that it is suspended approximately 1 foot (ft) above the surface of the water. The distance on the tape directly above the waterline (i.e., where the water meets the bank) is recorded as the initial point. The first measurement is made at the first point where there is adequate water depth (i.e., at least 0.2 ft) and measurable velocity. At this point, three measurements are made, including water depth, velocity, and distance from the bank (the initial point). Subsequent depth, velocity, and distance measurements are made incrementally across the entire width of the channel. Data from the field measurements are entered into a computer model that calculates the stream's cross-sectional profile from the depth and distance from bank measurements. Total flow across the channel is determined by integrating the velocity measurements over the cross-sectional surface area of the stream channel. The result is an instantaneous flow measurement in cubic feet per second.

A StreamPro Acoustic Doppler Current Profiler (ADCP) is used to measure mid- and high-stage flow conditions. The StreamPro ADCP is the USGS instrument of choice for measuring flows nationwide (Oberg et al., 2005). The instrument is pulled across the stream either by walking across a bridge or attaching the unit to a tagline. Data are collected in real time and transmitted by a wireless data link to a PC. Data can be viewed in real time and are typically post-processed following the field event in the office.

Rating curves are extended to high stream stages not measured using site-specific survey information and the Chézy–Manning formula (Linsley et al., 1982). The Chézy–Manning formula is an empirical formula for open channel flow, or flow driven by gravity, as follows:

$$Q = (1.486/n)AR^{2/3}S^{1/2}$$

where:

Q	=	flow
n	=	Manning Roughness coefficient
A	=	cross-sectional area

R = hydraulic radius

S = hydraulic slope

The hydraulic radius is derived as follows:

$R = A/P$

where:

A = cross-sectional area of flow (ft^2)

P = wetted perimeter (ft)

The Chézy–Manning formula was developed for conditions of uniform flow in which the water surface profile and energy gradient are parallel to the streambed and the area, hydraulic radius, and depth remain constant throughout the reach. Field surveys of the channel geometry of each MLS will be conducted to compute the channel characteristics for each station.

Channel Surveys

Channel surveys will be conducted at the MLS station to gather basic hydraulic measurements of the receiving water channels and to derive stream discharge using the Chézy–Manning formula. Channel surveys will be conducted using a DeWalt self-leveling rotary laser. The cross-section survey involves placing endpoints at the highest point of the channel on each bank. A measuring tape is stretched between the endpoints such that the zero end of the tape is attached to the endpoint on the left bank of the channel (looking downstream). Channel depth is measured across the channel from a stadia rod that is vertical and level from the channel bottom. The channel thalweg surveys are conducted for the reach upstream and downstream of the cross-section. The average channel slope is calculated from the survey data.

Channel survey data are used with the Chézy–Manning formula to produce a rating curve for each sampling station. Each rating curve is calibrated using instantaneous flow measurements by adjusting the formula roughness coefficient.

United States Geological Survey Watersheds

SMR-MLS-2 is located downstream of two USGS flow monitoring stations on the Santa Margarita River. The flow data from SMR-MLS-2 will be compared to the data obtained at the USGS gauging stations. These USGS gauging stations are used to estimate the annual flow volumes for the watershed. Data from the USGS gauging stations will also be used to validate flow monitoring data collected at the MLS since both use standard flow rating techniques for the watershed.

2.10.5 Bioassessment

Dry weather receiving water bioassessment monitoring will be conducted in accordance with Provisions D.1.c.(5) and D.1.e.(1)(a) of the Permit. Dry weather receiving water bioassessment monitoring will include bioassessment at the receiving water monitoring stations and participation in the SMC Regional Monitoring Program. In-stream bioassessment analyses are used to assess the cumulative impacts of discharges to aquatic species including benthic invertebrates, algae, fish, and plants. They are designed to directly measure the biological and physical condition of a watershed. Additionally, bioassessments indirectly measure the impacts of cumulative, sub-lethal doses of pollutants and may detect impacts that chemical and toxicity monitoring cannot. However, there are some limitations to the current procedures. Per the USEPA's Rapid Bioassessment

Protocol guidance, an accurate assessment of stream biological data is difficult because natural variability cannot be controlled.

The following paragraphs describe the details of how bioassessment monitoring will be conducted in the Upper SMR and Middle SMR subwatersheds.

Bioassessments involve assessment of the physical in-stream and riparian habitat, benthic macroinvertebrates, and algae. Bioassessments will be conducted according to the most current SWAMP SOP, which includes assessment techniques for benthic macroinvertebrates, algae, and physical habitat. CSCI scores will be calculated from benthic macroinvertebrate and algae data. The SWAMP SOP for bioassessment and algal assessment is provided in **Appendix 5D**. Bioassessments may be conducted in accordance with the SMC Regional Bioassessment monitoring program. Refer to the Monitoring Annual Reports for updates and status of special studies.

Benthic Macroinvertebrate Sampling and CSCI Metrics

Benthic macroinvertebrates, which include crustaceans such as crayfish, mollusks such as clams and snails, aquatic worms and the larval forms of aquatic insects such as stonefly and mayfly nymphs, are collected from the streams using specialized nets. A monitoring reach is delineated and then 21 transects are spaced equidistant across the reach. Prior to any other disturbance of the stream, field crews begin at the downstream transect and proceed upstream, disturbing a 1-foot square section of substrate at every other transect, resulting in one composite sample. The contents of the net are then placed into sample jars that are labeled and preserved prior to delivery to the laboratory for sample analyses. Detailed protocols may be found in **Appendix 5D**. At the laboratory, the organisms are sorted and identified, and the count of organisms in each taxon is recorded. The counts are used to calculate the CSCI score.

Bioassessment: Physical Habitat Characterization

Physical habitat data collected as part of the current SWAMP Bioassessment protocol consist of a wide variety of measures of both in-stream and associated riparian areas. This is done by first collecting in-stream water quality measurements with field meters. The stream reach is then partitioned into 11 main and 10 inter-transects, each spaced either 7.5 or 12.5 meters apart (depending upon the stream width). At each main transect, three measurements of stream size are collected: wetted width, bankfull width, and bankfull height. Water depth and particle size are recorded at five equidistant point counts along each of the 21 transects at the left bank, 25%, 50%, and 75% of stream width, and at the right bank. The presence of coarse particulate organic matter (CPOM), percent cobble embeddedness, microalgae, macroalgae, and macrophytes are also recorded at each of the five points. A measure of overhead canopy cover is taken from the center of each main transect with a handheld densiometer while facing upstream, downstream, and towards the left and right banks (from the downstream perspective). Riparian vegetation coverage on each bank, human influence, and in-stream habitat complexity are all recorded using a categorical scoring system. In addition to these measurements, flow habitats present are recorded at each inter-transect according to a categorical classification system.

Once physical habitat observations have been collected at each of the main and inter-transects, reach-wide data are collected, including stream sinuosity, stream discharge, and gradient. The final habitat characterization task is to score each station qualitatively for three parameters: epifaunal cover, sediment deposition, and channel alteration.

Bioassessment: Algae Sampling

Algal indicators can be monitored as part of a bioassessment including percent algal cover, algal taxonomic composition, and algal biomass. The percent algal cover can be recorded during the standard physical habitat assessment with sample collection. The SWAMP SOP describes how to collect a composite algae sample that can be used to quantify chlorophyll a, AFDM, diatom assemblage, and/or soft-bodied algal assemblages depending on the purpose of the study. After CSCI samples have been collected, algae samples are collected in the same manner, with field crews working upstream from transect to transect collecting a sample from an undisturbed location. Samples are kept out of the sun to reduce degradation of chlorophyll a, limit cell division post-collection, and protect algae from desiccation. The SWAMP SOP for collecting stream algae samples describes methodology to collect and preserve a quantitative algal sample from various types of substrates and when different forms of algae are present and are described in detail in **Appendix 5D**.

The following paragraphs describe the details of how bioassessment monitoring will be conducted in the Lower SMR subwatershed.

Bioassessment surveys will be conducted during the spring/summer dry season bioassessment index period, typically from April through July in Southern California. Bioassessment monitoring at the LTMS will be conducted once (during one monitoring season) during the five year Permit cycle. SMC bioassessment monitoring will be conducted annually throughout the course of the Permit.

The SWAMP sampling protocol includes the collection of stream benthic macroinvertebrates (BMI) and algae and also assesses the physical quality and condition of the streambed and banks in detail. California Rapid Assessment Method (CRAM) assessments incorporate broader buffer zone and land use attributes than SWAMP, and also provide a numerical quality score for each station. BMI reside in streams for periods ranging from a month to several years, and have varying sensitivities to the multiple stressors associated with urban runoff. Using species specific tolerance values and community species composition, numerical biometric indices are calculated, allowing for comparison of relative habitat health among streams in a region. By assessing the invertebrate and algal community structure of a stream, a cumulative measure of stream habitat health and ecological response is obtained.

A general description of the methods incorporated in the bioassessment sampling program are presented below. If any of the protocols listed below are updated as of 2019, the current version of the referenced documents should be used. Sampling protocols for the collection of BMI, algae, and physical habitat data will follow the SWAMP SOP. Physical habitat quality of the monitoring stations will be assessed using the CRAM for riverine wetlands (Collins et al., 2012). Laboratory sample processing will incorporate the SWAMP laboratory SOP (Woodward et al., 2012). Taxonomic identifications are to be to the standard taxonomic level II (species or genus level for most insects, genus level for Chironomidae, and class or order for most non-insects) as defined by the most recent version of the *Southwestern Association of Freshwater Invertebrate Taxonomists* (SAFIT) *List of Macroinvertebrate Taxa from California and Adjacent States and Ecoregions; and Standard Taxonomic Effort* (Richards and Rogers, 2011). Biological community scoring indices will be calculated for BMI using the California Stream Condition Index (CSCI) (Mazor et al., 2016a), and algae taxonomy data will be analyzed using the Southern California Algal Index of Biotic Integrity (IBI) (SCCWRP, 2014; Fetcher et al., 2014). The current SMC Workplan *Bioassessment Survey of the Stormwater Monitoring Coalition, Workplan for Years 2015 through 2019, Version 1.0* (SMC Workplan) (SCCWRP, 2015) will expire for the 2019-2020

bioassessment monitoring season (spring/summer of 2020). It is anticipated that the SMC will generate/revise the workplan with support from the SMC Executive Committee and Workgroup to cover the 2020 spring/summer monitoring season.

Laboratory analyses includes BMI taxonomy, BMI taxonomic quality control (QC) analysis by the California Department of Fish and Wildlife (CDFW) Aquatic Bioassessment Laboratory, benthic algae taxonomy (soft algae and diatoms), and chemistry analyses. Algae samples will be collected and processed for ash-free dry mass (AFDM) and chlorophyll-a analysis in addition to taxonomy. BMI data analyses include a taxonomic listing of all BMIs identified in the surveys and calculation of associated biological metrics, including the Index of Biological Integrity (IBI) and the California Stream Condition Index (CSCI). The CSCI is a newly developed analytical tool, finalized in 2013 (Mazor et al., 2016), that is applicable statewide in California and is now being utilized in place of the IBI to assess the health of freshwater streams. The CSCI combines a predictive multi-metric index (pMMI) (a measure of ecological structure) with a predictive observed to expected ratio (O/E) index (a measure of taxonomic completeness), and also incorporates local watershed geology and climate factors. The predictive components of the CSCI scoring tool allow for comparisons of the site being scored to a subset of other sites in California that the CSCI determines to be most similar. Algal data analyses includes a taxonomic listing of all taxa identified and calculation of algal metrics and three algal IBIs (Fetscher et al., 2014). These data are typically available in February of the year following the survey (i.e., in February 2021 for the 2019-2020 monitoring year).

Water quality parameters are also analyzed as part of the physical habitat quality assessment at each station. Field parameters are measured using a multi-parameter water quality meter (YSI Model 6920v2, or similar) and include water temperature, specific conductivity, salinity, pH, turbidity, and DO. Stream flow velocity is measured with a portable flowmeter, or visually estimated when the water is too shallow for use of the flowmeter. Parameters are compared to applicable Basin Plan water quality objectives.

2.10.6 Hydromodification Monitoring

2.10.6.1 HMP Monitoring Methods (2016 HMP Stations)

The following information is specific to hydromodification data collection from the Meadowview Stream and Warm Springs Channel stations within the Middle SMR subwatershed in accordance with the 2016 HMP:

In order to complete the HMP Monitoring outline in Section 5.3.1.3 of the WQIP, stream surveys will be conducted using an alternative method employing an Unmanned Aerial Vehicle. With the help of aerial photography captured using UAV technology, photogrammetric techniques can be utilized to extract 3D data in a defined coordinate system. The UAV can achieve 5cm absolute vertical accuracy, and slightly heightened horizontal accuracy. In applying this technology to hydromodification monitoring, heat maps can be created as well as cut/fill exhibits showing temporal change in grade over the entire monitoring site, rather than solely relying on cross-section positions.

2.10.6.2 Dry Weather Receiving Water Hydromodification Monitoring Methods (Upper SMR and Middle SMR Stations)

The following information is specific to hydromodification monitoring data collection from the long-term receiving water station in the Upper SMR subwatershed and the Middle SMR:

Most of the methods which will be utilized during Dry Weather Receiving Water Hydromodification Monitoring at the long-term receiving water stations are borrowed from standardized protocols which are also being applied in the 2015-2019 Stormwater Monitoring Coalition (SMC) Regional Monitoring Program. By using protocols consistent with the SMC Regional Program, the results from the hydromodification monitoring may be compared to other SMC stream condition data.

The primary standard protocol used for hydromodification monitoring will be *Hydromodification Screening Tools: Field Manual for Assessing Channel Susceptibility* (Bledsoe et al., 2010). Key components of this protocol include methods for the measurement of the following:

1. Bank angle
2. Bank height
3. Stream gradient at the assessment reach scale
4. Median substrate particle size (d_{50})
5. Vertical susceptibility
6. Lateral susceptibility

In addition to the field measures, the following landscape GIS metrics will be calculated:

1. Contributing drainage area above the point of interest
2. Mean annual area-weighted precipitation
3. Geomorphic confinement: valley bottom width at site
4. Valley slope (longitudinal gradient) at 500 m scale
5. Upstream land use coverage

To provide a standardized assessment of the presence and condition of vegetation and habitat integrity, relevant attributes of the California Rapid Assessment Method (CRAM) module for riverine wetland (Collins et al., 2013) will be applied. These included the hydrology, physical structure, and biotic structure attributes of the protocol. These attributes evaluate metrics including channel stability, riverine entrenchment ratio, structural patch richness, topographic complexity, and plant community composition and structure. CRAM is a protocol developed and calibrated to be used state-wide and is thereby applicable to the wide variety of ecological and climate regimes present in California. However, as a result of much of Riverside County being in a relatively arid part of the state, those CRAM attributes related to rainfall totals such as riparian vegetation and floodplain characteristics may be naturally biased towards lower scores, independent of anthropogenic impacts, particularly in ephemeral streams.

Channel gradient and habitat characterizations for substrate complexity, sediment deposition and channel alteration will be assessed using the relevant components and methods of the SWAMP SOP. Additional attributes of the sites that will be documented included simple measurements of channel width and depth, dimensions of eroded bank areas, as well as photo-documentation of erosion and habitat impacts.

A stream reach will be delineated using the lesser of either approximately 20 bankfull widths or 200 meters within a stream segment that will be considered hydrogeomorphically homogeneous. Once the stream reach is delineated, the risk potential for mass wasting (erosion) will be quantified.

At three representative transects, bank angle and height will be measured on both left and right banks using a stadia rod and gravity-driven protractor. Photographs will be taken of each transect where bank angle is measured to document conditions for later reference. To estimate the median particle size (d_{50}), the stream substrate will be assessed at 100 points throughout each reach. Observations to assist in determining vertical and lateral susceptibility to bank wasting will then be assessed. Vertical susceptibility will first be evaluated by recording the status of three streambed parameters: composition of the stream substrate, armoring potential (i.e. bed consolidation), and grade control presence and effectiveness. Lateral susceptibility will then be assessed through a decision tree using a combination of vertical susceptibility rating, bank stability threshold, and valley width index to determine the lateral susceptibility on a scale of 1 to 5 (a rating of 5 indicates a stream bank that has a very high susceptibility to wasting).

Alternatively, stream surveys may be conducted using the Unmanned Aerial Vehicle method similar to that used for the HMP Monitoring. With the help of aerial photography captured using UAV technology, photogrammetric techniques can be utilized to extract 3D data in a defined coordinate system. The UAV can achieve 5 cm absolute vertical accuracy, and slightly heightened horizontal accuracy. In applying this technology to hydromodification monitoring, heat maps can be created as well as cut/fill exhibits showing temporal change in grade over the entire monitoring site, rather than solely relying on cross-section positions.

2.10.6.3 Dry Weather Receiving Water Hydromodification Monitoring Methods (Lower SMR Station)

The following are details pertaining to hydromodification data collection in the Lower SMR subwatershed:

Channel surveys will be conducted using a DeWalt self-leveling rotary laser. The cross-section survey involves placing endpoints at the highest point of the channel on each bank. A measuring tape will be stretched between the endpoints such that the zero end of the tape is attached to the endpoint on the left bank of the channel (looking downstream). Channel depth will be measured across the channel from a stadia rod that is vertical and level from the channel bottom. The channel thalweg surveys will be conducted for the reach upstream and downstream of the cross-section. The average channel slope will be calculated from the survey data. Measurements or estimates of dimensions of any bed or bank eroded areas, including length, width, and depth of any incisions, will be also be conducted during the channel survey.

The geomorphic assessment will be conducted to characterize the susceptibility of the channel and gather basic hydraulic measurements of the receiving water channels. The geomorphic assessment is comprised of the channel survey and the SCCWRP channel assessment tool. The SCCWRP Field Manual (Bledsoe et al., 2010) will be used to assess the vertical and lateral susceptibility of the receiving water channels. A suite of field measurements will also be made to characterize the channel bed and banks, and overall stability state. Sediment samples will be collected to characterize bed materials. Fixed-interval pebble counts will be performed for each reach where the channel bed is comprised of gravel or coarser material, and channel beds comprised of fine material will be noted as sand or cohesive materials (bed gradations are not required for channels with $D_{50} < 2$ mm).

Known or suspected cause(s) of existing downstream erosion or habitat impact, including flow, soil, slope, and vegetation conditions, as well as upstream land uses and contributing new and

existing development, will be assessed during a geographic information system (GIS) desktop exercise and the SCCWRP channel assessment tool.

Photographs will be taken using a digital camera with a built-in global positioning system (GPS), altimeter, and compass. Photo documentation will be conducted using the general procedures outlined in San Diego Water Board Stream Photo Documentation Procedures for 401 Water Quality Certifications Standard Operating Procedure (CARCD, 2001).

The following information will be recorded for each photograph: Project name, location, photographer and field team members, photo number, date, and time. At a minimum, photographs of channel surveys will be taken of the following:

- Long view up or down the stream (from stream level) showing changes in the stream bank and vegetation;
- Long view and medium view of streambed changes (e.g., thalweg, gravel, meanders);
- Long views from a bridge or other elevated position;
- Medium and close views of structures and plantings;
- Medium views of bars and banks, with a person (preferably holding a stadia rod) in view for scale; and
- Close views of streambed with a ruler or other common object in the view for scale

3 MS4 OUTFALL MONITORING PROGRAM

3.1 MS4 OUTFALL PROGRAM OVERVIEW

The program has the following components:

- MS4 Outfall Wet Weather Monitoring (**Section 3.2**)
- Dry Weather MS4 Outfall Discharge Field Screening Monitoring (**Section 3.3**)
- NSW Persistent Flow MS4 Outfall Discharge Monitoring (**Section 3.4**)
- MS4 Outfall Monitoring Program Sampling and Analysis Types (**Section 3.5**)
- Assessment and Reporting (as discussed in **Section 5.5** of the WQIP)

Sampling under this monitoring program will begin when the SMR WQIP is accepted by the Regional Water Board and will continue to be implemented through the permit term. The MS4 Outfall Monitoring Program will be implemented in the Middle SMR subwatershed and Lower SMR subwatershed areas only, as there are no major outfalls in the Upper SMR subwatershed area.

3.2 MS4 OUTFALL WET WEATHER MONITORING

This section will cover elements that are specific to wet weather monitoring events at the MS4 outfall monitoring stations. Detailed descriptions of standard procedures regarding equipment, staffing, logistics, sampling, and laboratory QA/QC can be found in **Appendix 5D**. Related elements that are specific to this monitoring program are discussed in the following sections.

3.2.1 MS4 Outfall Wet Weather Monitoring Mobilization Criteria

Wet weather monitoring will be conducted according to the mobilization criteria stated in **Section 2.2**. Additionally, if receiving water wet weather monitoring is conducted during a given monitoring year, then an attempt will be made to conduct MS4 outfall wet weather monitoring sampling concurrently with the receiving water monitoring, where possible, to improve assessments.

If upon a scheduled monitoring event, an MS4 outfall is found to be dry, the sampling event will be documented with monitoring results of zero, and appropriate findings will be documented in the Monitoring Annual Report.

3.2.2 MS4 Outfall Wet Weather Sampling Teams, Equipment, and Bottles

Sampling Teams

Teams will be comprised of two Copermittee and/or consultant field personnel. All samples will be delivered to the laboratory by field crews promptly following sample collection, and compositing, if applicable. Runners will be used as necessary to ensure samples are delivered to the laboratory within USEPA recommended holding times.

Wet Weather Sampling Equipment

Possible suggestions for equipment at any MS4 outfall wet weather monitoring station include the following:

- Data-logging flow meter
- Automated composite sampler with sample tubing
- Tipping bucket rain gauge
- 12-V DC power supply
- Data telemetry unit (as necessary)
- Portable field water quality meter(s)
- Wet weather gear
- Ice
- Field books with field data sheets, site maps, hospital routes, sampling procedures, equipment manuals and chains of custody
- Sample bottles
- A toolbox with tools such as nitrile gloves, headlamps, zip ties, diagonal cutters, adjustable wrenches, and screwdrivers to take samples and make adjustments as needed on equipment during the storm event
- Extra autosampler bottles to make bottle changes as needed
- A cellphone to maintain communication lines with the project manager and field lead.

Where practicable, automated equipment will be installed prior to a forecasted storm event that meets the criteria pursuant to **Section 2.4**. Detailed descriptions of monitoring equipment operation and functions are provided in **Appendix 5D.**

Installation and Maintenance

Wet weather MS4 discharge monitoring equipment may be installed as described in **Appendix 5D** for use during wet weather events. Prior to the start of each wet weather event the electronic equipment and clean tubing will be installed at each station. Upon completion of monitoring, the equipment will be removed from the site and stored at either the Copermittee's or consultant's office. Maintenance and calibration will be performed prior to monitoring each wet weather event per **Appendix 5D**.

Bottles

MS4 outfall wet weather composite samples may be collected directly into a 19-liter bottle or into individual ½-gallon bottles that will be composited at the laboratory. **Appendix 5D** contains additional information regarding sample bottles. **Table 3-1** below provides a summary of bottles required for MS4 outfall wet weather monitoring.

Table 3-1. MS4 Outfall Wet Weather Monitoring Bottle List

Constituent	Middle SMR Subwatershed	Lower SMR Subwatershed	Preservative	USEPA Recommended Holding Time
	Container Type Per Site[1]			
All other constituents (Chemistry)	1 x 19-Liter glass (& 1 spare 19-L glass) or 3 x 1-Gallon glass or As directed by the laboratory		≤6°C	48 hours (minimum)
Bacteriological	2 x 125-mL plastic (each)		$Na_2S_2O_3$	8 hours
Total Hardness (as $CACO_3$)[2]	1 x 1 L amber glass	2 x 1 pint poly	HNO_3	180 days

1. Container Type may vary based on equivalent recommended by ELAP certified laboratory.
2. As per Table C-5 of Provision C.2.a, sampling will include a measure of receiving water hardness.

3.2.3 MS4 Outfall Wet Weather Data Collection

For most constituents, wet weather monitoring will consist of composite samples collected for a duration adequate to be representative of changes in pollutant concentrations and runoff flows using one of the following techniques:

- Time-weighted composite samples composed of discrete samples collected over the length of the storm or the first 24-hour period, whichever is shorter,
- Flow-weighted composite samples collected over the length of the storm or a typical 24-hour period, whichever is shorter, or
- If automated compositing is not feasible, composite samples may be collected using a minimum of four grab samples, collected during the first 24 hours of the storm water discharge, or for the entire storm water discharge if the storm event is less than 24 hours.

Grab samples may be collected for the following constituents during wet weather monitoring: pH, temperature, specific conductivity, dissolved oxygen, turbidity, hardness, and indicator bacteria. If the stormwater runoff is less than 2 hours, the grab sample will be collected as close to the peak of flow as possible. MS4 outfall monitoring will occur during the wet season as required to capture one wet weather event. The following types of samples will be collected at each MS4 outfall:

- Composite Samples
  - Chemistry time-weighted, flow-weighted, or four-grab sample composite samples
- Grab samples
  - Bacteriological grab samples
  - Hardness (if composite sample is not collected)
- *In-situ* field measurements
  - Temperature
  - pH

- Specific conductivity
- Dissolved oxygen
- Turbidity

- Field Observations
  - A narrative description of the station that includes the location, date and duration of the storm event(s) sampled, rainfall estimates of the storm event, and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event.
- Flow Measurements
  - The flow rates and volumes measured or estimated (data from nearby USGS gauging stations may be utilized, or flow rates may be measured or estimated in accordance with the USEPA Storm Water Sampling Guidance Document [EPA-833-B-92-001], Section 3.2.1).

Constituents for analysis and detailed sampling methods for the Middle SMR subwatershed are available in **Table 3-2** and **Appendix 5D**, respectively. Constituents for analysis and detailed sampling methods for the Lower SMR subwatershed are available in **Table 3-3** and **Section 3.5**, respectively.

Table 3-2. MS4 Outfall Wet Weather Monitoring Constituents for Analysis in the Middle SMR Subwatershed[1]

Analyte Group	Constituents
Conventionals	Total Dissolved Solids, Turbidity, Sulfate
Nutrients	Total Phosphorus, Nitrate + Nitrite, Total Nitrogen, Orthophosphate, Total Kjeldahl Nitrogen, Ammonia
Hardness	Total Hardness[2]
Metals (Total and Dissolved)	Aluminum, Cadmium, Copper, Iron, Lead, Manganese, Selenium, Silver, Zinc
Pesticides	Chlorpyrifos, Diazinon
Indicator Bacteria	Total Coliform, Fecal Coliform, *Enterococcus*, *E. Coli*
N/A	Constituents identified to be the cause for impairment for CWA section 303(d) Listings within the WMA related to non-pollutants[3]

1. The constituents to be monitored during MS4 outfall wet weather monitoring will be adapted as the constituents contributing to the highest priority water quality condition (based on the assessment procedures outlined in Chapter 2 of the WQIP), Clean Water Act 303(d) list, and storm water action level constituents change over time. Changes to the constituent list will be described within the Annual Report and implemented the following reporting year.
2. As described in Footnote 2 of **Table 3-1**, sampling will include a measure of receiving water hardness.
3. Certain 303(d) listings within the San Diego Region correspond to non-pollutants (e.g., toxicity, benthic community effects). Upon identification of the constituent which is the cause of the non-pollutant 303(d) listing within the WMA, that constituent will be monitored during MS4 outfall wet weather monitoring.

Table 3-3. MS4 Outfall Wet Weather Monitoring Constituents for Analysis in the Lower SMR Subwatershed

Analyte Group	Constituents
Conventionals	Total Dissolved Solids, Total Suspended Solids, Total Organic Carbon, Dissolved Organic Carbon, Sulfate, MBAS
Nutrients	Total Phosphorus, Nitrate + Nitrite, Total Nitrogen, Orthophosphate, Total Kjeldahl Nitrogen, Ammonia
Hardness	Total Hardness (as $CACO_3$)[1]
Metals (Total and Dissolved)	Aluminum, Cadmium, Copper, Iron, Lead, Manganese, Selenium, Silver, Zinc
Pesticides	Chlorpyrifos, Diazinon
Indicator Bacteria	*E. coli*, Fecal Coliform, *Enterococcus*, Total Coliform
N/A	Constituents identified to be the cause for impairment for CWA section 303(d) Listings within the WMA related to non-pollutants[2]

1. As per Table C-5 of Provision C.2.a., certain SALs for MS4 discharges to receiving waters will be developed on a case-by-case basis based on site-specific water quality data (receiving water hardness). As such, sampling will include a measure of receiving water hardness.
2. Certain 303(d) listings within the San Diego Region correspond to non-pollutants (e.g., toxicity, benthic community effects). Upon identification of the constituent which is the cause of the non-pollutant 303(d) listing within the WMA, that constituent will be monitored during MS4 outfall wet weather monitoring.

Continuous flow monitoring may occur at the MS4 outfall during the period of sample collection. Constituents for analysis and detailed sampling methods are available in **Appendix 5D**. Refer to **Section 5** for required data records and COC information.

The following are specific procedures followed within the Lower SMR subwatershed for wet weather MS4 outfall data collection:

In the Lower Santa Margarita Watershed, the County of San Diego proposes to monitor at the outfall to the brow ditch HST01 (**Table 3-4**). HST01 discharges to Rainbow Creek and is a TMDL monitoring location in dry weather. Wet weather monitoring under the transitional monitoring program began at this station during the 2016-2017 monitoring year in order to develop baseline concentrations prior to potential BMP implementation. The drainage area of this station is primarily rural residential and agriculture. This station also receives flow from MS4-SMG-089, which will be sampled separately if it flows during the monitoring event. The drainage area of this station is smaller as shown in **Table 3-4**. Samples will be composited between the two stations based on the runoff observed from each area to represent the flow-weighted composite at HST01.

Table 3-4 Wet Weather MS4 Monitoring Locations

Station ID	Latitude	Longitude	Location	Outfall Size (in)	Drainage Area (acres)
HST01	33.41526	-117.15204	Brow Ditch to Rainbow Creek @ Huffstatler St.	36	93.2
MS4-SMG-089*	33.41532	-117.15192	Channel across from HST01 @ Huffstatler St.	36	30.3

*Station will be monitored if flow is observed and a composite will be developed that represents the total drainage to HST01.

Automated samples for chemistry will be collected with a Sigma 900MAX autosampler (or similar type device). Teflon-lined tubing will be installed and secured at each monitoring location prior to the wet weather event. The autosampler will be deployed by the field team upon arrival at each site. Samples will be pumped with the autosampler into a clean glass bottle. The sample bottle will be appropriately labeled with the sample identifier, date, and time, and will be preserved on ice for transport to the laboratory. After compositing, samples will be subsampled into the appropriate bottles for analysis. Grab samples will be collected using either the Sigma 900MAX autosampler or a glass bottle connected to a sample pole that will be used to collect the sample directly from the outfall location. Nitrile or latex gloves will be worn during sample handling.

Field parameter measurements will be made using a YSI Inc. 6600 series water quality probe or similar type device. Calibration of the instruments will be conducted prior to each sampling event according to the manufacturer's specifications, and the instruments will be calibrated following each sampling event. Calibration records must be kept on file.

Microbiology samples will be collected using sterile techniques. Nitrile or latex type gloves will be worn during sample handling. During the sampling event, a 100-mL sterile bacteria bottle will be secured to a sample pole that will be used to collect the sample directly from the outfall location. Care will be employed to not allow contact with area structures or the bottom sediments. The container will be opened only for the needed time to collect the sample and will then be closed immediately following sample collection. If it is suspected that the container was compromised at any time, the sample container will be discarded, and a new sample will be collected with a new sample bottle. The sample bottle must be filled only to the 100-mL mark on the bottle (not over topped or under filled).

3.3 DRY WEATHER MS4 OUTFALL DISCHARGE FIELD SCREENING MONITORING

The Permit requires that each Copermittee continue to perform the dry weather MS4 outfall discharge field screening monitoring which has already commenced. Detailed descriptions of standard procedures regarding staffing, logistics, and flow estimation procedures can be found in **Appendix 5D**. Dry weather MS4 outfall discharge field screening monitoring must be preceded by at least 72 hours of dry conditions (<0.1 inch of precipitation). The following visual observations will be collected at each MS4 outfall discharge monitoring station inspected:

- Station identification and location
- Presence of flow, or pooled or ponded water
- If flow is present:
    - Flow estimation (i.e. width of water surface, approximate depth of water, approximate flow velocity, flow rate)
    - Flow characteristics (i.e. presence of floatables, surface scum, sheens, odor, color)
    - Flow source(s) suspected or identified from non-storm water source investigation
    - Flow source(s) eliminated during non-storm water source identification, if applicable
- If pooled or ponded water is present:
    - Characteristics of pooled or ponded water (i.e. presence of floatables, surface scum, sheens, odor, color)

- Known or suspected source(s) of pooled or ponded water

- Station description (i.e. deposits or stains, vegetation condition, structural condition, and observable biology)
- Presence and assessment of trash in and around station
- Evidence or signs of illicit connections or illegal dumping

Based on the visual observations collected during dry weather MS4 outfall discharge field screening monitoring, Copermittees will conduct the following follow-up actions (consistent with the IDDE requirements of the Permit):

- Immediately conduct field investigations for obvious illicit discharges to identify potential sources of NSW discharges,
- Maintain records and a database of the following information:
  - Location of incident, including hydrologic subarea, portion of MS4 receiving the non-storm water or illicit discharge, and point of discharge or potential discharge from MS4 to receiving water
  - Source of information initiating the investigation (e.g., public reports, staff or contractor reports and notifications, field screening, etc.)
  - Date the information used to initiate the investigation was received
  - Date the investigation was initiated
  - Dates of follow-up investigations
  - Identified or suspected source of the illicit discharge or connection, if determined
  - Known or suspected related incidents, if any
  - Result of the investigation, if applicable
  - If a source cannot be identified and the investigation is not continued, document the response and submit a summary of the non-storm water discharges and illicit discharges and connections investigated and eliminated within its jurisdiction with each Water Quality Improvement Plan Annual Report,
- Seek to identify the source(s) of NSW discharges from the MS4 when there is evidence of NSW having been discharged into or from the MS4,
- Update the Copermittee's MS4 outfall station inventory as necessary given the information collected, and
- Evaluate field observations together with existing information available from prior reports, inspections and monitoring results to determine whether any observed flowing, pooled, or ponded waters are likely to be transient or persistent flow.[5]

[5] Persistent flow is defined as the presence of flowing, pooled, or ponded water more than 72 hours after a measureable rainfall event of 0.1 inch or greater during three consecutive monitoring and/or inspection events. All other flowing, pooled, or ponded water is considered transient.

3.4 NON-STORMWATER PERSISTENT FLOW MS4 OUTFALL DISCHARGE MONITORING

This section will cover elements that are specific to NSW persistent flow MS4 outfall discharge monitoring. Detailed descriptions of standard procedures regarding equipment, staffing, logistics, sampling, and laboratory QA/QC can be found in **Appendix 5D**. Related elements that are specific to this monitoring program are discussed in the following sections.

3.4.1 Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring Mobilization Criteria

If receiving water dry weather monitoring is conducted during the monitoring year, NSW persistent flow MS4 outfall discharge monitoring will be conducted in coordination with the receiving water monitoring event, where possible, to improve assessments. NSW persistent flow MS4 outfall discharge monitoring must be preceded by at least 72 hours of dry conditions (<0.1 inch of precipitation). Additional information regarding mobilization criteria is available in **Appendix 5D**. If upon a scheduled monitoring event, an MS4 outfall is found to be dry, the sampling event will be documented with monitoring results of zero, and appropriate findings will be documented in the Annual Report. No future attempts to repeat that MS4 outfall sampling will be conducted within the subject monitoring year.

3.4.2 Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring Sampling Teams, Equipment, and Bottles

Sampling Teams

Monitoring teams will be comprised of two Copermittee or consultant field personnel. Additional teams may be implemented, as necessary. All samples will be delivered to the laboratory by field crews promptly following sample collection. Runners will be used as necessary to ensure samples are delivered to the laboratory within USEPA recommended holding times.

Dry Weather Sampling Equipment

Possible suggestions for equipment at any NSW persistent flow MS4 outfall discharge monitoring station include the following:

- Handheld velocity meter (if sufficient flow exists)
- Measuring tape and stop watch (if velocity meter is unavailable)
- A bucket with bucket liners and a funnel (if safety concerns prevent *in situ* sample collection)
- Portable water quality field meter(s)
- Pre-cleaned secondary sample collection vessel (optional - used in very low flows)
- Ice
- Field books with field data sheets, site maps, hospital routes, sampling procedures, equipment manuals and chains of custody
- Sample bottles
- Nitrile gloves

- Extra autosampler bottles to make bottle changes as needed
- A cellphone to maintain communication lines with the project manager and field lead.

Detailed descriptions of monitoring equipment operation and functions are provided in **Appendix 5D**.

Installation and Maintenance

Monitoring locations will not require equipment installation as grab samples will be collected. If safety concerns prevent field crews from collecting *in situ* grab samples, a bucket with clean bucket liners may be used to collect grab samples, which will be poured into respective sample containers through a thoroughly field rinsed funnel. Maintenance and calibration will be performed prior to each NSW persistent flow MS4 outfall discharge monitoring event per **Appendix 5D**.

Bottles

All samples will be collected as grab samples. Bottles are identified in **Table 3-5.**

Table 3-5. NSW Persistent Flow MS4 Outfall Discharge Monitoring Bottle List

Constituent	Container Type[1]	Preservative	Holding Time
Bacteriological	2 x 125-mL plastic (each)	$Na_2S_2O_3$, ≤6°C	8 hours
Total and Dissolved Metals Total Hardness (as $CACO_3$)[2]	2 x 1-pint poly	HNO_3, ≤6°C	180 days
OP Pesticides	5 x 1 L amber glass	≤6°C	7 days
TDS, TSS, Nitrite as N, Nitrate as N, MBAS	1 x 1 quart	≤6°C	TDS, TSS – 7 days; Nitrate, MBAS, Nitrite – 2 days
Nitrogen-Kjeldahl, Ammonia, Total Phosphorus, Orthophosphate	2 x 1-pint poly	H_2SO_4, ≤6°C	28 days

1. Container type may vary based on equivalent recommended by ELAP certified laboratory.
2. As per Table C-3 of Provision C.1.a.(2), certain NALs for MS4 discharges to freshwater receiving waters will be developed on a case-by-case basis based on site-specific water quality data (receiving water hardness). As such, total hardness will be collected in the respective receiving water as well as at the outfall.

3.4.3 Non-Storm Water Persistent Flow MS4 Outfall Discharge Monitoring Data Collection

NSW persistent flow MS4 outfall discharge monitoring will occur semi-annually per station, according to the schedule described in **Section 3.4.2**. One sample from the downstream receiving water of the MS4 outfall will be collected and analyzed for hardness. Per instruction received from the Regional Board (phone conversation on 11/04/14):

- If the downstream receiving water station is ponded, one grab sample (for hardness analysis) will be collected and the observation recorded as ponded on the field data sheet.
- If the receiving water station is dry, and the only contributing flows in the receiving water streambed are from the outfall then one grab sample (for hardness analysis) will be collected downstream of the outfall station where flowing water can be sampled before it infiltrates in a pond, and the observation recorded as ponded on the field data sheet.

- If the MS4 outfall's immediate receiving water be dry with no flow connectivity from the MS4 discharge, then one grab sample will be collected from the corresponding receiving water monitoring station (for hardness analysis).

The following types of samples will be collected at each MS4 outfall:

- Grab samples
  - Chemistry grab samples
  - Bacteriological grab samples
  - Hardness
- *In-situ* field measurements
  - Temperature
  - pH
  - Specific conductivity
  - Dissolved oxygen
  - Turbidity
- Field Observations
  - Station identification and location
  - Presence of flow, or pooled or ponded water
  - If flow is present:
    - Flow estimation (i.e. width of water surface, approximate depth of water, approximate flow velocity, flow rate)
    - Flow characteristics (i.e. presence of floatables, surface scum, sheens, odor, color)
    - Flow source(s) suspected or identified from non-storm water source investigation
    - Flow source(s) eliminated during non-storm water source identification
  - If pooled or ponded water is present:
    - Characteristics of pooled or ponded water (i.e. presence of floatables, surface scum, sheens, odor, color)
    - Known or suspected source(s) of pooled or ponded water
  - Station description (i.e. deposits or stains, vegetation condition, structural condition, and observable biology)
  - Presence and assessment of trash in and around station
  - Evidence or signs of illicit connections or illegal dumping

Constituents for analysis are available in **Table 3-6**, respectively. Detailed sampling methods are available in **Appendix 5D** and **Section 3.5** for the Middle and Lower SMR subwatersheds, respectively.

Table 3-6. NSW Persistent Flow MS4 Outfall Discharge Monitoring Constituents for Analysis[1]

Analyte Group	Constituents
Conventionals	Total Dissolved Solids, Total Suspended Solids, Total Hardness[2], Sulfate, MBAS
Nutrients	Total Phosphorus, Orthophosphate, Nitrate + Nitrite, Total Kjeldahl Nitrogen, Ammonia, Total Nitrogen
Metals (Total and Dissolved)	Aluminum, Cadmium, Copper, Chromium (III), Chromium (VI), Iron, Manganese, Lead, Nickel, Selenium, Silver, Zinc
Pesticides	Chlorpyrifos, Diazinon[3]
Indicator Bacteria	Total Coliform, Fecal Coliform, *E. Coli*, *Enterococccus*
N/A	Constituents identified to be the cause for impairment for CWA section 303(d) Listings within the WMA related to non-pollutants[4]

1. The constituents to be monitored during NSW persistent flow MS4 outfall discharge monitoring will be adapted as the highest priority water quality condition, Clean Water Act 303(d) list, and non-storm water action level constituents change over time. Changes to the constituent list will be described within the Annual Report and implemented the following reporting year.
2. As described in Footnote 2 of **Table 3-5**, hardness will be monitored within the receiving water and at the outfall.
3. To be obtained in the Middle SMR subwatershed only.
4. Certain 303(d) listings within the San Diego Region correspond to non-pollutants (e.g., toxicity, benthic community effects). Upon identification of the constituent which is the cause of the non-pollutant 303(d) listing within the WMA, that constituent will be monitored during NSW persistent flow MS4 outfall discharge monitoring.

Refer to **Section 5** for required data records and COC information.

3.5 MS4 OUTFALL MONITORING PROGRAM SAMPLING AND ANALYSES TYPES

Sections 3.2 through **3.4** describe the specific analyses and sample types applicable to MS4 outfall monitoring. **Appendix 5D** includes the units, methods, and RLs for constituent analysis for wet weather and dry weather samples collected under the Middle SMR subwatershed MS4 Outfall Monitoring Program. **Table 2-4** includes the units, methods, and RLs for constituent analysis for wet weather and dry weather samples collected under the Lower SMR subwatershed MS4 Outfall Monitoring Program.

Chemistry Composite Samples

Further detail regarding standard time-weighted composite sampling is provided in **Appendix 5D**. NSW persistent flow MS4 outfall discharge samples will not be composited (subject to change as needed).

Grab Sampling

NSW persistent flow MS4 outfall discharge monitoring grab samples will be collected using protocols and methods outlined in **Appendix 5D**. Sample containers will be determined according to the type of monitoring conducted under **Sections 3.2** through **3.4**.

If the flow cannot be accessed directly, a grab pole may be used with the sample container attached to collect the sample or grab samples may be collected by manually operating the automated equipment to fill the appropriate bottles. If flows are too shallow to submerge the sample container directly, a secondary, pre-cleaned, sample vessel may be used to transfer sample water into the sample containers. If ponded water is observed at a monitoring location, conditions must be recorded on the field data sheet.

***In-situ* Field Measurements**

In-situ water quality field measurements may be collected at each sampling point once during each monitoring event. *In-situ* field measurements will be collected concurrently with grab sample collection.

Standard procedures for collecting *in-situ* water quality parameters are described in **Appendix 5D**. Duplicate field meters will be carried when possible. If meter failure occurs, the field team will attempt to use a back-up meter or another team's meter. As a last resort, the laboratory will be instructed to analyze for any missing parameters according to the methods provided according to **Appendix 5D**.

Flow Monitoring

The following describes flow monitoring conducted within the Middle SMR subwatershed:

Flow monitoring may be performed at the MS4 outfall monitoring stations to record stage, velocity (where applicable), and instantaneous flow, which is calculated by the flow meter. Hydrologic connectivity with the receiving water will also be assessed, where possible. Continuous flow measurements may be collected during composite sampling for the length of the sampling event. Flow measurements may also be collected with the use of a handheld velocity meter and measuring the width and depth of the monitored waters.

At a minimum, instantaneous flow measurements will be collected once during each monitoring event at each of the NSW persistent flow MS4 outfall discharge monitoring stations, and receiving water sampling points. If a flow meter is not available, flow is insufficient to conduct composite sampling, or ponded water is present, flow may be estimated on the field data sheet by measuring:

- Width of the water surface,
- Approximate depth of the water, and
- Approximate flow velocity.

Ponded water will be indicated by 0.0 cfs. No flow or no discharge will be indicated by "DRY" and 0.0 cfs (i.e., will be documented as Visited, Not Sampled).

The following describes flow monitoring conducted within the Lower SMR subwatershed:

Flow will be monitored at HST01 and MS4-SMG-089 to determine the volume of runoff of the storm events. Flow will be estimated with a Sigma 920 Flow Meter (or similar type device) with an area velocity sensor and pressure transducer (**Figure 3-1**). The sensor measures water level and velocity. Flow will be calculated based on the cross-sectional area of the pipe, level of water, slope, and velocity and used to set sample collection during storm events. The sensor will be secured to the bottom of each channel or pipe (site dependent) (**Figure 3-2**).

Figure 3-1. Sigma 910 Flow Meter and Area/Velocity Pressure Sensor

Figure 3-2. Example of Sensor Installation

At each site, the pipe diameter and slope will be measured and recorded. Level and flow measurements will be logged at five-minute intervals for the duration of the monitoring event when using continuous logging devices. Data downloads will occur after the monitoring event is complete. Due to the velocities and potential for debris to be carried by storm flows, it is possible that the flow sensor may be damaged during storm flows. Damage to a flow sensor may result in a data gap of actual recorded flows. In this event, flows from the respective drainage area will be modeled for any data gaps based on the drainage area and impervious cover. If manual sampling techniques are used, periodic level measurements will be made throughout the event at specific intervals (e.g., with every grab sample, or every 15 minutes, 30 minutes, or hourly throughout the event).

4 TMDL MONITORING

4.1 TMDL RECEIVING WATER MONITORING OVERVIEW

The TMDL monitoring program for Rainbow Creek includes the following water quality monitoring: field observations, photo documentation, analytical water sample collection, flow measurements, and physicochemical measurements. Monitoring in the watershed to assess compliance with the nutrient waste load allocations and receiving water quality targets in the TMDL is to be conducted according to the *Sampling and Analysis Plan for Rainbow Creek Nutrient Reduction TMDL Implementation Water Quality Monitoring* (TMDL Monitoring Plan) required initially by the 319(h) grant agreement and more recently by the MS4 Permit. The results of the monitoring will be used to assist in characterizing baseline conditions, evaluating best management practice (BMP) effectiveness to reduce nutrient loading to the creek, and to track changes in water quality and the trajectory to attaining the TMDL goals over time.

4.1.1 TMDL Sampling Teams, Equipment, and Bottles

Monitoring teams will consist of trained and qualified field personnel. TMDL sampling will follow the Sampling and Analysis Plan for Rainbow Creek Nutrient Reduction TMDL Implementation Water Quality Monitoring (County of San Diego, 2010) (TMDL Monitoring Plan) and the QAPP for Nutrient Source Reduction Program in the Rainbow Creek Watershed Water Quality Monitoring (County of San Diego, 2013).

Water quality monitoring will include field observation, photo documentation, analytical water sample collection, flow measurements, and physicochemical measurements. Qualitative field observations will be made during each site visit whether or not ponded or flowing water is present. These observations are intended to provide a general assessment of the site and include variables such as odor, water clarity, presence or absence of floatable matter, visible deposits/ stains, vegetative density, and biological status.

4.1.2 Receiving Water Sampling Locations and Sampling Frequency

Samples will be collected during dry weather at the fourteen sampling locations specified by the TMDL Monitoring Plan and **Chapter 5** of the WQIP at a minimum frequency of once per month at approximately 30-day intervals. Monitoring will not be conducted during any rain event greater than 0.1 inches, and samples are not to be collected following the rain event until the water level at the sampling location returns to within approximately 10% of the pre-rain creek level. Stations HST01 and HST02 monitor MS4 discharges, whereas the remaining twelve stations are located in the receiving water.

4.1.3 Sampling Techniques and Field and Laboratory Water Quality Constituents

When water is present, all sampling locations will be monitored for in-situ parameters (pH, temperature, conductivity, turbidity, and DO). Grab samples will be collected for the constituents as summarized in **Table 4-1**. A hand-held flow meter or the floating leaf technique will be used to measure current velocity.

Table 4-1. Water Quality Analytical Parameters for Rainbow Creek TMDL

Parameter	Sample Type	Analytical Method
Field Monitoring		
pH	Analyzed in Field	YSI 6920 Water Quality Data Sonde- Use per Manufacturer's instructions
Temperature	Analyzed in Field	
Conductivity	Analyzed in Field	
Dissolved Oxygen	Analyzed in Field	
Turbidity	Analyzed in Field	
Laboratory Monitoring		
TDS	Grab	SM 2340 C
Iron	Grab	EPA 200.7
Sulfate	Grab	SM 4500 SO4 E
Nitrate-N	Grab	SM 4500 NO3 E
Nitrite-N	Grab	SM 4500 NO2 B
TKN	Grab	SM 4500 N C
Ammonia-N	Grab	SM 4500 NH3 B, C
Total Nitrogen	Calculated	Calculated
Total Phosphate	Calculated	SM 4500 P B, E
Orthophosphate-P	Grab	SM 4500 P E

Each site will be photographed to provide additional information and documentation of site conditions. Estimated flow rates will be used to calculate pollutant mass loading, and will help to prioritize storm drains for future investigations and to identify significant changes in flow that may be indicative of an illegal release upstream.

Water physicochemical properties will be measured at each site where water is flowing or ponded. The parameters will be measured be measured *in situ* or from a collection cup using a YSI 6920 V2 data sonde. All data will be recorded on the Field Data Sheet.

4.2 DRY WEATHER MS4 OUTFALL MONITORING IN THE RAINBOW CREEK SUBWATERSHED

Progress toward compliance with the Nutrient TMDL in Rainbow Creek may be demonstrated in several ways, as outlined in Attachment E.3 of the Permit. One of these pathways to demonstrate compliance is to show that there is "no direct or indirect discharge from the Responsible Copermittee's MS4 to the receiving water". To this end, dry weather monitoring at MS4 outfalls in the Rainbow Creek watershed will continue to be conducted to determine whether there are direct or indirect dry weather discharges from the County of San Diego's MS4 to Rainbow Creek.

4.2.1 Dry Weather Storm Drain Outfall Monitoring

MS4 outfall monitoring is to be conducted during dry weather (i.e., not within 72 hours of a rain event totaling 0.1 inch or greater). At stations where flow is observed, flow rates will be measured or estimated using either a portable flow meter or the leaf method. Field parameters measured using a YSI water quality probe will include pH, temperature, conductivity, DO and turbidity. Grab samples will be collected and analyzed for ammonia, nitrate as N, nitrite as N, TKN, and orthophosphate as P. Total nitrogen and total phosphate as P will be calculated once laboratory results are received (Michael Baker, 2016). Data collected during the 2017-2018 monitoring year will be combined with all previous data collected at these outfalls.

4.2.2 Monitoring Locations and Sampling Frequency

As summarized in the *Rainbow Creek Nutrient Reduction and Management Plan* (Michael Baker, 2016), MS4 outfalls discharging to Rainbow Creek were identified through desktop analysis and field reconnaissance where field crews identified specific locations of all outfalls and MS4 segments with the potential to discharge to Rainbow Creek during dry weather. The inventory of MS4 outfalls voluntarily monitored under the program is presented in **Table 4-2** and shown in **Figure 4-1**.

Table 4-2. List of Rainbow Creek MS4 Monitoring Locations

Station ID	Latitude	Longitude	Location
MS4-SMG-056	33.41741	-117.15581	Outfall at Old Hwy. 395; 20' south of 2nd St.
MS4-SMG-057	33.42032	-117.15387	Outfall at Old Hwy. 395; 1,160' north of 2nd St.
MS4-SMG-058	33.42533	-117.15020	Outfall at Old Hwy. 395; 3,290' north of 2nd St.
MS4-SMG-061	33.42957	-117.14476	Outfall at Rainbow Valley Blvd.; 1,025' west of Old Hwy. 395.
MS4-SMG-063	33.40928	-117.16562	Outfall at Rainbow Glen Rd.; 535' west of Rainbow Hills Rd. (Under Bridge).
MS4-SMG-086	33.41813	-117.14783	Channel at 2526 Rainbow Valley Blvd.
MS4-SMG-087/ SMG19	33.42356	-117.14336	Channel at 2826 Rainbow Valley Blvd.
MS4-SMG-088	33.41769	-117.15201	Channel at Huffstatler Street and Second Street.
MS4-SMG-089*	33.41532	-117.15192	Channel across from HST01 at Huffstatler Street.
MS4-SMG-091*	33.40338	-117.20411	Outfall at Willow Glen Rd.; 125' north of Red Mountain Heights Dr.
MS4-SMG-092*	33.40931	-117.16584	Outfall in ceiling of west box culvert at Rainbow Glen Rd.; 200' east of Oak Crest Rd.
MS4-SMG-094*	33.41925	-117.15460	Outfall at Old Hwy. 395, 700' north of 2nd Street
MS4-SMG-095*	33.42198	-117.15277	Outfall at Old Hwy. 395, 1,800' north of 2nd Street
MS4-SMG-096*	33.42249	-117.15237	Outfall at Old Hwy. 395, 2,000' north of 2nd Street
MS4-SMG-097*	33.42376	-117.15146	Outfall at Old Hwy. 395, 2,600' north of 2nd Street
MS4-SMG-098*	33.42755	-117.14764	Outfall at Old Hwy. 295; 1,350 south of West Rainbow Valley Blvd.
MS4-SMG-099*	33.42933	-117.14470	Outfall on hillside of Old Highway 395; 50' south of West Rainbow Valley Blvd.
MS4-SMG-100*	33.42957	-117.14459	Outfall on hillside at intersection of Old Hwy. 395 and West Rainbow Valley Blvd.
MS4-SMG-101*	33.42275	-117.14398	Outfall at 2855 Rainbow Valley Blvd. (Rainbow Valley Nursery entrance)
HST01	33.41526	-117.15204	Brow Ditch to Rainbow Creek at Huffstatler Street.
HST02	33.41174	-117.15196	Pipe from nursery along Huffstatler Street.

*New site added in 2016-2017

Source: Rainbow Creek Nutrient Reduction and Management Plan (Michael Baker, 2016) and County of San Diego Department of Public Works (County of San Diego Outfall Monitoring at Rainbow Creek, 2017).

All MS4 monitoring locations listed in **Table 4-2** will be monitored during dry weather (no daily precipitation greater than 0.1 inches within 72 hours prior to the visit). As this is a voluntary monitoring program, the County will conduct, at a minimum, quarterly monitoring. However, if field staff are available, more frequent monitoring will be conducted to demonstrate progress toward meeting the goals of the Rainbow Creek TMDL.

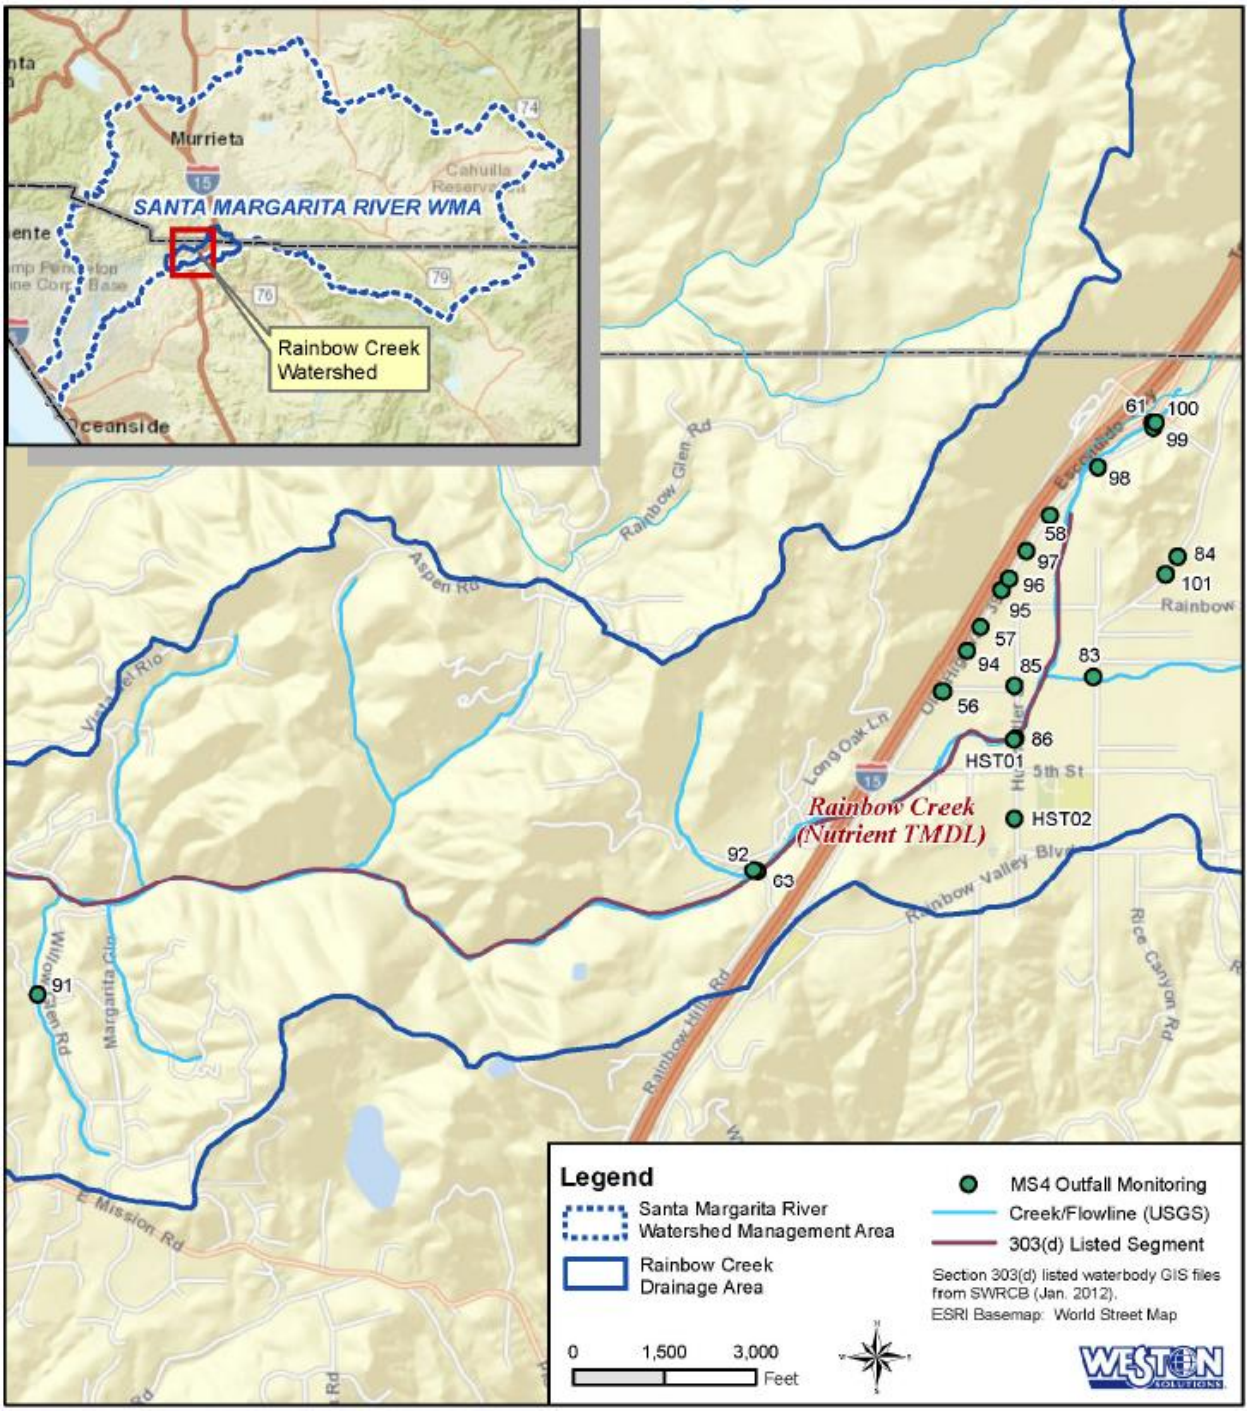

Figure 4-1. Rainbow Creek Dry Weather MS4 Outfall Monitoring Locations

5 DATA RECORDS AND MANAGEMENT

Detailed data records and management requirements for the Upper SMR and Middle SMR subwatersheds are provided in **Appendix 5D**.

The following sections outline the data records and management requirements for the Lower SMR subwatershed.

5.1 EVENT DATA RECORDS AND CHAINS OF CUSTODY (COCS)

Achieving a high-quality data set requires rigorous documentation of field activities and defensible COCs, as well as timely review of laboratory data. This section reviews the data required to be recorded on the field data sheets, sample labels, COCs, and laboratory turnaround time for data reports and Electronic Data Deliverables (EDDs) (i.e., simple text EDDs and SWAMP compatible).

5.1.1 Field Data Sheets

During sampling activities, a record of the monitoring event, including grab sample times, and *in-situ* field measurements, will be kept on a field data. Field data sheets will document site or station ID, station name, sample ID(s), sample date, sample time, site conditions, including flow and/or ponded water, connectivity between MS4 discharges and surface receiving waters, sources of water and relative contribution of sources (including rising groundwater) the presence of trash, and any other applicable issues and information. Field data sheets and COCs will be reviewed immediately following each mobilization, and discrepancies will be resolved.

5.1.2 Chain of Custody Procedures

Samples will be considered to be in custody if they are (1) in the custodian's possession or view, (2) retained in a secured place (under lock) with restricted access, or (3) placed in a container and secured with an official seal such that the sample could not be reached without breaking the seal. The principal documents used to identify samples and to document possession will be COC records, field logbooks, and field tracking forms. COC procedures will be used for samples throughout the collection, transport, and analytical process.

COC procedures will be initiated during sample collection. A COC record will be provided with each sample or group of samples. Each person who will have custody of the samples will sign the form and ensure the samples will not be left unattended unless properly secured. Documentation of sample handling and custody includes the following:

- Sample identifier.
- Sample collection date and time.
- Any special notations on sample characteristics or analysis.
- Initials of the person collecting the sample.
- Date the sample was sent to the analytical laboratory.
- Shipping company and waybill information.

Completed COC forms will be placed in a plastic envelope and kept inside the cooler containing the samples. Once delivered to the analytical laboratory, the COC form will be signed by the person receiving the samples. The condition of the samples will be noted and recorded by the receiver.

COC records will be included in the final reports prepared by the analytical laboratories and are considered an integral part of the report.

5.1.3 Sampling Transport, Shipping, and Storage Procedures

All samples collected in the field will initially be placed on ice and stored in the dark. Prior to shipping or transport, sample containers will be packed inside coolers with ice. COC forms will be filled out, and the original signed COC forms will be inserted in a sealable plastic bag and placed inside the coolers. The cooler lids will be securely taped shut and then samples will be delivered or shipped on ice to the appropriate analytical laboratory for analysis.

5.1.4 QA/QC Field Procedures

Field measurements will be made using a water quality probe, such as a YSI data sonde, that has been calibrated according to manufacturer specifications. Operation of field equipment will be conducted as per manufacturer instructions. Calibrations will be performed and recorded to ensure accurate functionality. Proper storage and maintenance procedures will be followed.

QA/QC for sampling processes begins with proper collection of the samples to minimize the possibility of contamination. Samples will be collected in appropriate containers, kept on wet ice during the sampling event, and placed into coolers along with completed COC for transfer to the analytical laboratory. Field crews will ensure that sampling containers are being filled properly and the requirement to avoid contamination of samples at all times is met. The field data log sheets will include empirical observations of the site and water quality characteristics. Field duplicates will be collected at a minimum of 5% of total project sample count. A minimum of one equipment blank will be collected during monitoring events.

5.1.5 QA/QC Laboratory Analyses

The laboratory analysis of the samples will be performed under the guidelines of the analytical laboratory's respective SOPs and QAPPs as well as meet the quality objectives set forth in this Monitoring and Assessment Plan. This includes analyzing the appropriate QC laboratory controls for each analysis in accordance with SWAMP criteria such as laboratory blanks and duplicates, matrix spike/matrix spike duplicates (MS/MSDs), certified or standard reference materials, and surrogates.

5.2 DATA MANAGEMENT

Each Copermittee or their subcontractor(s) will document and track the aspects of the sample collection process, including generating field logs at each site and COC forms for the samples collected. COC forms will accompany samples to the appropriate laboratory for analysis. Each laboratory will document and track the aspects of receipt and storage, analyses, and reporting related to their respective samples.

A database of information collected during the monitoring will be maintained by each Copermittee or their subcontractor(s). The database will include field observations, data sheets, COC records, and analytical results. The original data sheets, statistical worksheets, and reports produced will be accumulated into project-specific files maintained in file cabinets following submittal of the draft report. Data from outside contractors will be kept exactly as received. Monitoring data and analytical results will be uploaded into California Environmental Data Exchange Network (CEDEN).

Copies of the final report, including laboratory results and field records, will be maintained for a minimum of five years after project completion.

The Copermittee or Contractor Project Manager will document and track the aspects of the sample collection process, including generating field logs at each site and COC forms for the samples collected. COC forms will accompany samples to the appropriate laboratories for analysis. Each analytical laboratory will document and track the aspects of sample receipt and storage, analyses, and reporting. Each analytical laboratory's results will be stored in a database system at their office and will be provided to the Copermittee or Contractor Project Manager both electronically and by hard copy. Further details of each laboratory's data management protocols can be found in each laboratory's respective QAPP.

Field logs and analytical data will be entered into or transferred to the Copermittee or Contractor's database. After the data is added to the database, the Contractor Project QA Officer will validate the data by checking for errors and ensure the data is complete. The database will be updated with finalized data. The results of the laboratory QC analyses will be reported with the final data. Any QC samples that fail to meet specified QC criteria will be identified, and the corresponding data will be appropriately qualified in the final report. All QA/QC records will be kept on file for review by regulatory agency personnel. Once data is finalized, all monitoring data and analytical results will be formatted and uploaded into CEDEN. All records should be maintained for at least five years.

ACRONYMS, ABBREVIATIONS AND DEFINITIONS

2010 SMR MS4 Permit	The SMR MS4 Permit requires the Copermittees to develop and implement a stormwater management program to reduce the contamination of stormwater runoff and prohibit illicit discharges
ACCWP	Alameda Countywide Clean Water Program
Adequate Sump	
ALERT	Automated Local Evaluation in Real Time: a local flood warning system for a local agency such as a county or a city
Alternative Compliance Option	
Alternative Performance Standard	
BAHM	Bay Area Hydrology Model
Bed Sediment	Term to define the coarse-grained portion of the sediment load
Bed Sediment Load	The Bed Sediment (material that moves along the bed by sliding or saltating) and part of the suspended sediment load including particle size fractions in the channel Bed Sediments.
BMP	Best Management Practice
CALVEG	A California statewide system for describing vegetation types in mapping their general distributions
CCCWP	Contra Costa Clean Water Program
CEM	Channel Evolution Model
Channel Stability Performance Standard	Requires that geomorphic stability within a channel will not be compromised as a result of receiving runoff from a PDP
Comprehensive Regional BMP	Regional runoff management systems that address water quality, hydrologic, and fluvial geomorphologic requirements for PDPs larger than 100 acres.
Copermittees	County, District, and Cities of Murrieta, Temecula and Wildomar
Critical Shear Stress	Threshold above which motion of bed sediment is initiated.
D_{50}	Median grain size diameter
DAMP	Drainage Area Management Plan
DCV	Design Capture Volume
Ep	stream erosion potential
Erosion	The process by which soil and rock are removed from the Earth's surface by exogenic processes such as wind or water flow, and then transported and deposited in other locations
ESA	Environmentally Sensitive Areas
FSURMP	Fairfield-Suisun Urban Runoff Management Program
GIS	Geographical Information System
HEC-HMS	Hydrologic Engineering Center – Hydrologic Modeling System
HMP	Hydromodification Management Plan

HMP Criteria	All PDPs must use continuous simulation to ensure that post-project runoff flow rates and durations for the PDP shall not exceed pre-development, naturally occurring, runoff flow rates and durations by more than 10% over more than 10% the length of the flow duration curve, from 10% of the 2-year runoff event up to the 10-year runoff event.
HMP Management Bank	
HMP Performance Standard	The Hydrologic Performance and Sediment Supply Performance Standards
HR	Hydraulic Radius
HRU/GLU Analysis	Hydrologic Response Units/Geomorphic Landscape Units
HSPF	Hydrologic Simulation Program FORTRAN, distributed by USEPA
Hydrologic Control BMPs	A technique, measure or structural control that is used for a given set of conditions to manage the quantity and improve the quality of stormwater runoff
Hydrologic Performance Standard	Consists of matching or reducing the flow duration curve of post-development conditions to that of pre-existing, naturally occurring conditions, for the range of geomorphically significant flows (10% of the 2-year runoff event up to the 10-year runoff event).
Hydromodification	The change in the natural watershed hydrologic processes and runoff characteristics (i.e., interception, infiltration, overland flow, interflow and groundwater flow) caused by urbanization or other land use changes that result in increased stream flows and sediment transport. In addition, alteration of stream and river channels, such as stream channelization, concrete lining, installation of dams and water impoundments, and excessive streambank and shoreline erosion are also considered Hydromodification, due to their disruption of natural watershed hydrologic processes.
IMP	Integrated Management Practices
K	Soil erosion factor
LEED	Leadership in Energy and Environmental Design
LID	Low Impact Development
LSPC	Loading Simulation Program in C++
Management Bank	A Bank consisting of regional HMP management projects where PDPs can buy HMP management credits if it is determined that implementing onsite Hydrologic Control BMPs is infeasible.
MHHW	Mean Higher High Water
MS4	Municipal Separate Storm Sewer System
MSHCP	Western Riverside County Multi-Species Habitat Conservation Plan
MUSLE	Modified Universal Soil Loss Equation. A mathematical model that describes soil erosion processes
NOAA	National Oceanic and Atmospheric Administration
NPDES	National Pollutant Discharge Elimination System
NRCS	Natural Resource Conservation Service
PDP	Priority Development Project
Project Specific WQMP	Project Specific Water Quality Management Plan
Q or Qw	Flow
Qcrit - Qc	Critical flow
Qcp	Geomorphically critical flow – 10% of the 2-year flow
District	Riverside County Flood Control and Water Conservation District
Receiving Water	Water of the United States

RGO	Retail Gasoline Outlets: A category 2 PDP less than one acre that uses BMPs to reduce or eliminate pollution
RWQCB	Regional Water Quality Control Board
Saltation	
SCCWRP	Southern California Coastal Water Research Project
SCS	Soil Conservation Service
SCVURPPP	Santa Clara Valley Urban Runoff Pollution Prevention Program
SDRWQCB	San Diego California Regional Water Quality Control Board
SDHM	San Diego Hydromodification Model
Sediment Supply BMP	Site design principles to preserve onsite first-order or higher order streams that have been identified as significant contributors of bed sediment load.
Sediment Supply Performance Standard	Consists of maintaining the pre-project bed sediment supply to the downstream channel reach.
SMCWPPP	San Mateo Countywide Water Pollution Prevention Program
SMR	Santa Margarita Region
SMRHM	Santa Margarita Region Hydrology Model
SOHM	South Orange Hydrology Model
SSMP	Standard Stormwater Mitigation Plan, also known as WQMP (Water Quality Management Plan)
STOPPP	San Mateo County Stormwater Pollution Prevention Program
SUSMP	Standard Urban Stormwater Mitigation Plan
SWM SWMM	Stanford Watershed Model Stormwater Management Model; distributed by USEPA
SWMP	Stormwater Management Plan
SWRCB	State Water Resources Control Board
SWWM	Stormwater Management Model
TMDL	Total Maximum Daily Load
USACE	United States Army Corps of Engineers
USEPA	United States Environmental Protection Agency
User	The person using this guidance document to prepare analyze a projects and prepare a WQMP
USGS	United States Geological Survey
Wash Load	The portion of the total sediment load carried continuously in suspension by the flow, and generally consists of the finest particles.
WQMP	Water Quality Management Plan
WWHM	Western Washington Continuous Simulation Hydrology Model

Note to the User:

The Santa Margarita Region Hydromodification Management Plan (SMR HMP) uses the term "User" to refer to any public or private entities seeking the discretionary approval of new development or significant redevelop projects (Priority Development Projects [PDP]) by the Copermittee with jurisdiction over the project site. The SMR HMP employs the term "User" to identify the person responsible for submitting the Water Quality Management Plan (WQMP) that meets the performance standards set forth in the SMR HMP.

Simplified HMP Roadmap for User

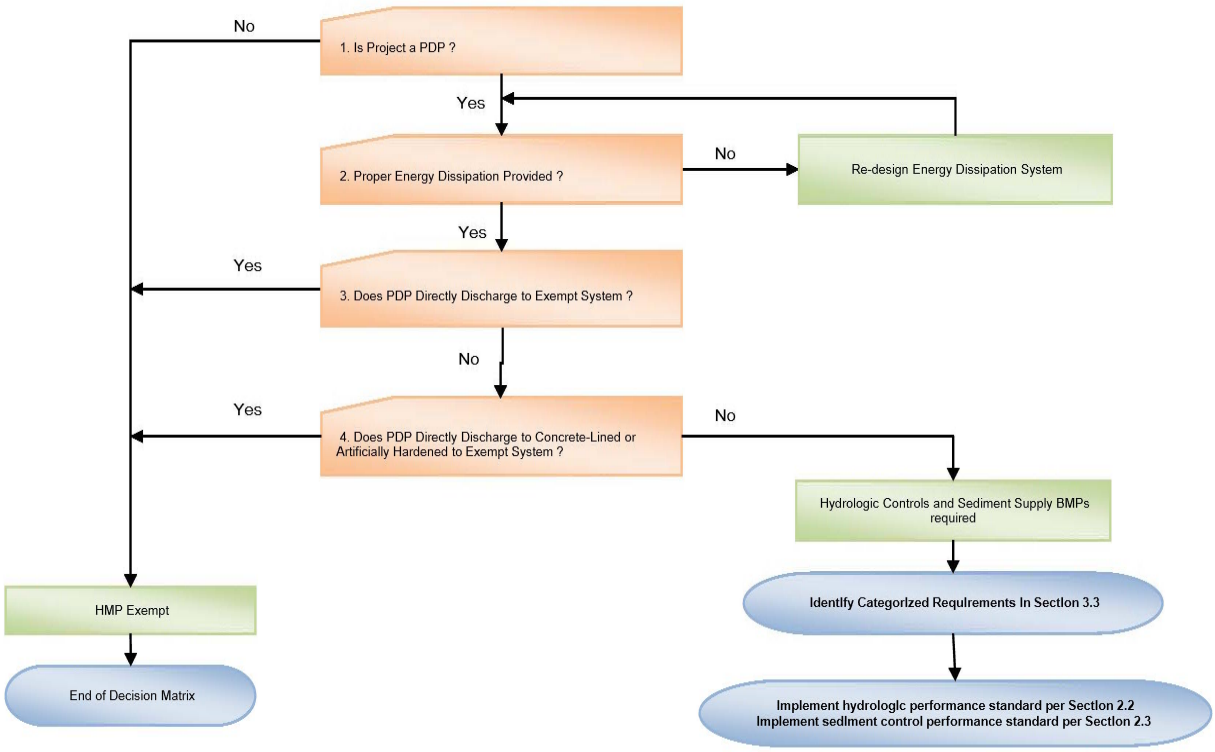
The Copermittees continue to reduce Hydromodification and flood risk through master planning and evaluating specific development projects to manage stormwater runoff. Additionally, the Santa Margarita Region Hydromodification Management Plan (SMR HMP) was developed by the Copermittees in response to Provision F.1.h of the 2010 SMR Municipal Separate Storm Sewer System (MS4) Permit (Order R9-2010-0016) to manage increases in runoff discharge rates and durations from Priority Development Projects (PDPs). The 2010 SMR MS4 Permit contains requirements specifying the methodology to be employed in the development of the HMP, including the development of hydrologic and sediment supply performance standards that will support maintenance of geomorphic stability in channels receiving runoff from PDPs.

The simplified HMP roadmap guides the User through the steps and the sections of the SMR HMP to be followed to:

1. Identify if the development project is subject to the requirements of the HMP; and
2. When required, guide the User in meeting the HMP requirements.

A User, who must meet Low Impact Development (LID) and Hydromodification requirements simultaneously, may refer to the SMR WQMP.

How to identify if my project is subject to the requirements of this HMP?



The User may refer to the HMP Decision Matrix presented in **Figure 1** to identify if the PDP is exempt from the requirements of the SMR HMP.

Conditions for exemption of development projects from HMP requirements must be documented by the User and may only be considered by the Copermittee with jurisdiction over the project site if:

- The project is not classified as PDP per Permit Provision F.1.d.;
- The proposed project discharges runoff directly to an exempt channel such as an exempt river reach, or an exempt reservoir. Or, if the proposed project discharges to an concrete-lined or artificially hardened channel, that extends to an exempt river reach or reservoir (See **Section 3.2.i**);
- The project discharges to a large river per the definition provided in Section 3.2.ii;

If the project is not exempt, the User should identify the categorized requirements that apply. For specific categorized requirements, the User may refer to **Section 3.3**. These requirements direct the User to implement, when required, Hydrologic Control BMPs and Sediment Supply BMPs following the approach listed in **Section 2.0**.

Figure 1. HMP Decision Matrix

What are the HMP Performance Standards that PDPs must meet?

Users must demonstrate compliance with the overall HMP Performance Standard, thus demonstrate compliance with the ***Hydrologic Performance Standard*** and the ***Sediment Supply Performance Standard***, respectively.

The Hydrologic Performance Standard consists of matching or reducing the flow duration curve of post-development conditions to that of pre-existing, naturally occurring conditions, for the range of geomorphically significant flows (10% of the 2-year runoff event up to the 10-year runoff event). The Sediment Supply Performance Standard consists of maintaining the pre-project Bed Sediment supply to the channel receiving runoff from the project site.

PDPs are categorized based on their size and type. Specific requirements are associated with each of the two categories. The User should refer to **Section 3.3** to identify the specific categorized requirements.

How to meet the Hydrologic Performance Standard?

This HMP includes a tool to provide continuous simulation of peak flow rates, from 10% of the 2-year runoff event up to the 10-year runoff event for PDPs. The tool is the Santa Margarita Region Hydrology Model (SMRHM), which is a Hydrologic Simulation Program FORTRAN (HSPF)

model based on the South Orange County Hydrology Model. This model allows Users to demonstrate compliance with the HMP Performance Standards through interactive graphic user interface. Details about how to use the model are provided in the 2013 SMRHM Guidance Document (see APPENDIX F).

In some situations, onsite Hydrologic Control BMPs may not be feasible due to identified constraints. In this case the User must investigate the feasibility of alternative options and must implement offsite Hydrologic Control BMPs or in-channel restoration or rehabilitation projects. The User should refer to **Section 2.2** for additional information.

How to meet the Sediment Supply Performance Standard?

The User may follow a three-step process, as identified in **Section 2.3,** to attain maintenance of the pre-project sediment supply to the channel receiving runoff from the project:

1. Determine whether the project site is a significant source of Bed Sediment load to the receiving channel.
2. Avoid significant Bed Sediment supply areas in the site design.
3. Replace significant Bed Sediment supply areas that are eliminated through development of the PDP.

If the three-step process is deemed infeasible, an alternative compliance option allows the User to model the site conditions and the receiving channel and provide additional management in site runoff to compensate for the reduction (or addition) of Bed Sediment Load. Specifics are detailed in **Section 2.3.ii**.

How to initiate compliance with the requirements of this HMP?

The User must integrate Hydrologic Control and Sediment Supply BMPs into the PDP design, and define the design specifics in the preliminary WQMP that should be submitted to the Copermittee with jurisdiction over the project site. The Copermittee with jurisdiction over the project site may approve the proposed design upon identification of compliance with the requirements of this HMP.

The User may refer to the SMR WQMP for complete guidelines on how to develop a WQMP for the PDP.

1.0 Introduction

1.1 SMR HMP Context

The SDRWQCB jurisdiction covers the portion of Riverside County that is located within the Santa Margarita Watershed referred to as the SMR. The Copermittees regulated under the 2010 SMR MS4 Permit are the Cities of Murrieta, Temecula, and Wildomar, as well as the County of Riverside and the Riverside County Flood Control and Water Conservation District (District).

The 2010 SMR MS4 Permit defines Hydromodification as:

> *The change in the natural watershed hydrologic processes and runoff characteristics (i.e., interception, infiltration, overland flow, interflow and groundwater flow) caused by urbanization or other land use changes that result in increased stream flows and sediment transport. In addition, alteration of stream and river channels, such as stream channelization, concrete lining, installation of dams and water impoundments, and excessive streambank and shoreline erosion are also considered Hydromodification, due to their disruption of natural watershed hydrologic processes.*

In addition to urban development activities, anthropogenic activities that may result in Hydromodification may include agriculture, forestry, mining, water withdrawal, climate change, and flow regulation by upstream reservoirs. Hydromodification can result in impacts on receiving channels, such as erosion, sedimentation, and potentially degradation of in-channel habitat. The degree to which a channel will erode or aggrade is a function of the increase or decrease in work (shear stress), the resistance of the channel bed and bank sediments – including vegetation (critical shear stress), the change in sediment delivery, and the geomorphic condition (soil lithology) of the channel.

Not all flows cause significant movement of Bed Sediment—only those which exceed the Critical Shear Stress of the sediments found in the channel bank and bed. Critical Shear Stress is the threshold above which motion of Bed Sediment is initiated. Urban development may increase the discharge rate, amount and timing of runoff, and associated shear stress exerted on the receiving channel by channel flows, may reduce sediment delivered to the channel, and can trigger erosion in the form of incision (channel downcutting), aggradation (deposition of sediment), widening (bank erosion), or both. Flow velocities that generate shear below Critical Shear Stress levels will not result in the channel's degradation and may result in aggradation.

The Copermittees continue to reduce factors that may lead to Hydromodification and reduce flood risk through master planning and evaluating specific development projects to manage stormwater runoff. Additionally, program Provision F.1.h of the Santa Margarita Region (SMR) Municipal Separate Storm Sewer System (MS4) Permit (Order R9-2010-0016) (2010 SMR MS4 Permit) issued by the San Diego California Regional Water Quality Control Board (SDRWQCB) requires that "Each Copermitee shall collaborate with the other Copermittees to develop and implement a Hydromodification Management Plan (HMP) to manage increases in runoff discharge rates and durations from all Priority Development Projects (PDPs)." Where receiving channels are already unstable due to natural or anthropogenic processes, Hydromodification

management may be thought of as a method to avoid accelerating or exacerbating existing Hydromodification. Where receiving channels are in a state of dynamic equilibrium, Hydromodification management may prevent the onset of accelerated erosion, sedimentation, lateral bank migration, aggradation, or impacts to in-channel vegetation.

The 2010 SMR MS4 Permit contains requirements specifying the methodology to be employed in development of the HMP. The 2010 SMR MS4 Permit requires the Copermittees to develop an HMP to address all PDPs (with certain exemptions) and to develop a HMP Performance Standard including a geomorphically-significant flow range that ensures the geomorphic stability within the channel. Supporting analyses must be based on continuous hydrologic simulation modeling. The loss of sediment supply due to the PDP must also be considered.

The SMR HMP addresses the impacts of Hydromodification on the channels receiving stormwater runoff from a PDP. As identified in **Section 1.2**, other anthropogenic stressors to the channels in the SMR are outside of the jurisdictional purview of the Copermittees.

The SMR HMP will serve as the technical documentation for Hydromodification aspects to support the LID BMP Design Handbook and the SMR WQMP. The LID BMP Design Handbook will be updated with Hydrologic Control and Sediment Supply BMPs. For BMP sizing and site planning purposes, Users and plan checkers may refer directly to the LID BMP Design Handbook and the SMR WQMP. The methodology for meeting LID and Hydromodification requirements, or LID requirements alone, will be identified in these documents.

1.2 SMR History and Historic Hydromodification Impacts

The Southern California Coastal Water Research Project (SCCWRP) characterizes the Santa Margarita River as one of the largest rivers in southern California whose course has remained unobstructed by dams and other artificial infrastructure from its confluence of Temecula Creek and Murrieta Creek to the Pacific Ocean (SCCWRP, 2007). The Santa Margarita River begins at the confluence of Temecula Creek and Murrieta Creek, in Southern Riverside County, and flows southwest successively through Temecula Canyon, a large floodplain in Camp Pendleton Marine Corps Base, and ultimately discharges into the Pacific Ocean. The Santa Margarita River Watershed drains a tributary area of 746-square miles and is physiologically split into a mountainous highland and broad, flat topped sea terrace. The boundary between the upper drainage basin and the coastal drainage basin transitions at the border between Riverside County and San Diego County. The construction of Vail Dam and Skinner Reservoir and historical urbanization within the SMR have progressively and significantly altered the hydrology and sediment transport regimes in the downstream channels. The intent of this section is not to quantify these impacts, but rather to describe the existence of these historic modifications.

1.2.i Water Reservoirs

Runoff from approximately 65% of the SMR has been controlled by the construction of Vail Dam and Skinner Reservoir. In 1974, the 44,200 acre-feet Lake Skinner was formed by construction of

a dam on Tucalota Creek. Skinner Lake creates a sump for surface flows and Bed Sediment that has been transported from the upper reaches of Tucalota Creek. Vail Lake is a 49,370 acre-feet reservoir located at the confluence of Temecula Creek, Wilson Creek, and Kolb Creek. The reservoir was built in 1949 by Vail Ranch to develop an irrigation system for expanding their agricultural activities. Since 1978, the reservoir has been operated by the Rancho California Water District to help replenish local groundwater.

Vail Lake and Skinner Lake are operated based on water supply and groundwater recharge considerations, and not for flood control purposes. Virtually all runoff received in these reservoirs is conserved for municipal, industrial, and agricultural use. Nonetheless, the storage capacity of each reservoir induces a management of peak flow rates and durations during storm events. The potential increases in flood flows resulting from urban development in the SMR are offset by the storage effect of the reservoirs (PWA, 2004).

1.2.ii Existing Surface Water and Groundwater Conditions

In 2013 the District conducted field reconnaissance to identify perennial channel segments within the SMR. These investigations identified that 97.3% of the stream segments in the SMR are ephemeral. Sources of dry-weather runoff, if any, were identified as predominantly from urban and agricultural irrigation runoff. The channel segments exhibiting dry weather flow were observed to be short and discontinuous, with the minor flows evaporating and/or infiltrating. There was no continuity of flow from the MS4 to the confluence of Murrieta and Temecula Creeks. Dry weather flows in the Santa Margarita River consist of deliveries of imported water by the Rancho California Water District to Camp Pendleton augmented with minor amounts of rising groundwater that occur in the vicinity of the confluence of Murrieta and Temecula Creeks.

Surface runoff from the SMR does not augment the dry weather flows in the Santa Margarita River. Dry-weather runoff in the SMR evaporates and infiltrates prior to the confluence of Murrieta and Temecula Creeks. The creeks in the urbanized areas of the watershed, located primarily in the valley, are ephemeral and flows are observed only during and immediately after significant storm events. During major storms, after initial wetting, periods of intense rainfall result in rapid increases in channel flow in steep foothill and mountain areas. Runoff in channels in the watershed is derived primarily from rainfall, and as a result, channel flow exhibits monthly and seasonal variations similar to those shown by the precipitation records. There is a rapid decrease in channel flow at the conclusion of the winter precipitation season. Following severe storms, discharge in the larger channels often increases in a few hours from no flow, to a rate of thousands of cubic feet per second. Channel flows vary greatly from month to month and from season to season.

1.2.iii Historical Urbanization in the SMR

The Riverside County Drainage Area Management Plan (2007 DAMP) assumes that 92% of the SMR remained undeveloped as of 2010. Much of the remaining SMR lands will ultimately be incorporated into the Western Riverside County Multi-Species Habitat Conservation Plan

(MSHCP), which requires the ongoing conservation of 500,000 acres within the County. For the average annual event, it is estimated that approximately 89% of the volume of runoff in the SMR is due to non-urban land uses not regulated under the federal stormwater program (2007 DAMP).

1.3 SMR HMP Organization

The HMP is organized in two major sections, supported with technical appendices. The first major section identifies the HMP Performance Standards and identifies the applicable tools and measures to meet these standards. The second major section establishes specific categorized requirements for a User, based on a classification of the PDP and the susceptibility to Hydromodification of the channels receiving stormwater runoff from the PDP. The technical appendices reference the HMP development process and reporting requirements per 2010 SMR MS4 Permit Provision F.1.h.(5), provide a literature review of the state of the Hydromodification science per 2010 SMR MS4 Permit Provisions F.1.h.(1)(g) and F.1.h(1)(k), and incorporate the findings of HMP studies performed to classify channel segments per susceptibility category. The HMP also is required to identify areas with historic Hydromodification of Receiving Waters and that are tributary to documented low or very low Index of Biotic Integrity scores for potential opportunities for channel restoration or rehabilitation per Permit provisions F.1.h(1)(a) and F.1.h(1)(h), respectively.

It should be noted that this HMP has in large part been based on the San Diego HMP, which was developed by the San Diego Copermittees and the South Orange County HMP developed by the Copermittees of South Orange County. The San Diego HMP was approved by the SDRWQCB and served as the starting point for development of the SMR HMP.

2.0 SMR HMP Criteria and Performance Standards

The objective of this section is to identify the specific HMP criteria and Performance Standards for Hydromodification to be implemented. PDPs are required to implement Hydrologic Control BMPs so that post-project runoff flow rates and durations are similar to those found in pre-development conditions, i.e. naturally occurring conditions, flow rates and durations where they would result in an increased or decreased potential for erosion or significant impacts to Beneficial Uses (Permit Section F.1.h.). The purpose of this chapter is to identify the HMP criteria, detail the HMP applicability requirements, and provide a framework for alternative compliance.

2.1 HMP Criteria and Performance Standards

The HMP Criteria is designed to manage changes in runoff discharge rates and durations from PDPs:

> All PDPs must use continuous simulation to ensure that post-project runoff flow rates and durations for the PDP must not exceed pre-development, naturally occurring, runoff flow rates and durations by more than 10% over more than 10% the length of the flow duration curve, from 10% of the 2-year runoff event up to the 10-year runoff event.

Section F.1.h.(1)(d) of the 2010 SMR MS4 Permit identifies that PDPs are required to implement Hydrologic Control and Sediment Supply BMPs to meet the following Performance Standards such that that geomorphic stability within a channel will not be compromised as a result of receiving runoff from a PDP:

1. The Hydrologic Performance Standard, which consists of demonstrating flow duration matching for the range of geomorphically-significant flows. This HMP includes a tool to provide continuous simulation of peak flow rates, from 10% of the 2-year runoff event up to the 10-year runoff event for PDPs. The tool is the SMR Hydrology Model (SMRHM), which is a Hydrologic Simulation Program FORTRAN (HSPF) model based on the South Orange County Hydrology Model. This model allows Users to demonstrate compliance with the Hydrologic Performance Standard defined below through interactive graphic user interface. Details about how to use the model are provided in the 2013 SMRHM Guidance Manual (See APPENDIX G).

2. The Sediment Supply Performance Standard, which consists of the approximate maintenance of pre-project Bed Sediment supply. The general approach that a User must follow to demonstrate compliance with the Sediment Supply Performance Standard is described in **Section 2.3**.

Users managing a PDP must demonstrate compliance with the Hydrologic Performance Standard and the Sediment Supply Performance Standard. Compliance with these standards constitutes compliance with the overall HMP criteria.

As demonstrated in APPENDIX C , the lower flow threshold ($0.1Q_2$) satisfies Section F.1.h.(1)(b) in that it corresponds with the critical channel flow that produces the Critical Shear Stress that initiates channel Bed Sediment movement or that erodes the toe of channel banks of a soft-bottomed channel.

In addition, the Copermittees have selected the lower flow threshold ($0.1Q_2$) based on the results from the Flow Control Threshold Analysis performed for the San Diego HMP. The analysis evaluated the geomorphic stability of a channel under 170 scenarios that are representative of the typical watershed sizes, receiving channel dimensions, channel Bed Sediment, and rainfall conditions in San Diego County. As identified in Appendix C, the SMR is located within the Peninsular Ranges geomorphic zone; hence the results from the San Diego HMP Flow Control Threshold Analysis are applicable to the SMR. A copy of the Flow Control Threshold Analysis is available in APPENDIX J .

Alternatively, the User may put forth other low flow thresholds for individual PDPs, but other low flow thresholds will require site-specific justification, at the User's expense, using modeling or field tests to support the unique threshold value. For those PDPs that chose to perform a site-specific analysis, the selected lower flow threshold must also ensure that it meets the requirements of Section F.1.h.(1)(b) of the 2010 SMR MS4 Permit, i.e. the selected lower flow threshold must correspond to the critical channel flow that produces the critical shear stress that initiates channel Bed Sediment movement or that erodes the toe of channel banks. For a channel segment that is lined but not exempt by this HMP, the low flow threshold must be computed based on a comparable natural channel. The User may consult APPENDIX I to identify a site-specific low-flow threshold, as follows:

- A simplified approach, which consists of a critical flow sensitivity assessment, which provides the User with a general indication that a site-specific low flow threshold may be appropriate, but is not sufficient to quantify the threshold. The approach is consistent with the Flow Control Threshold Analysis, also referenced in APPENDIX J .

- Guidelines for performing a full-scale geomorphic assessment of the stability of the channel receiving runoff from a PDP that may be considered by the Copermittee with jurisdiction over the project site.

The HMP Performance Standard is also applicable to those PDPs that are unable to implement flow duration controls onsite or via a regional or sub-regional BMP that accepts discharges from the project, but is located outside of the project boundaries, but seek compliance through offsite Hydrologic Control BMP projects. The offsite Hydrologic Control BMP project must be capable of matching or reducing the equivalent flow duration curves from the PDP.

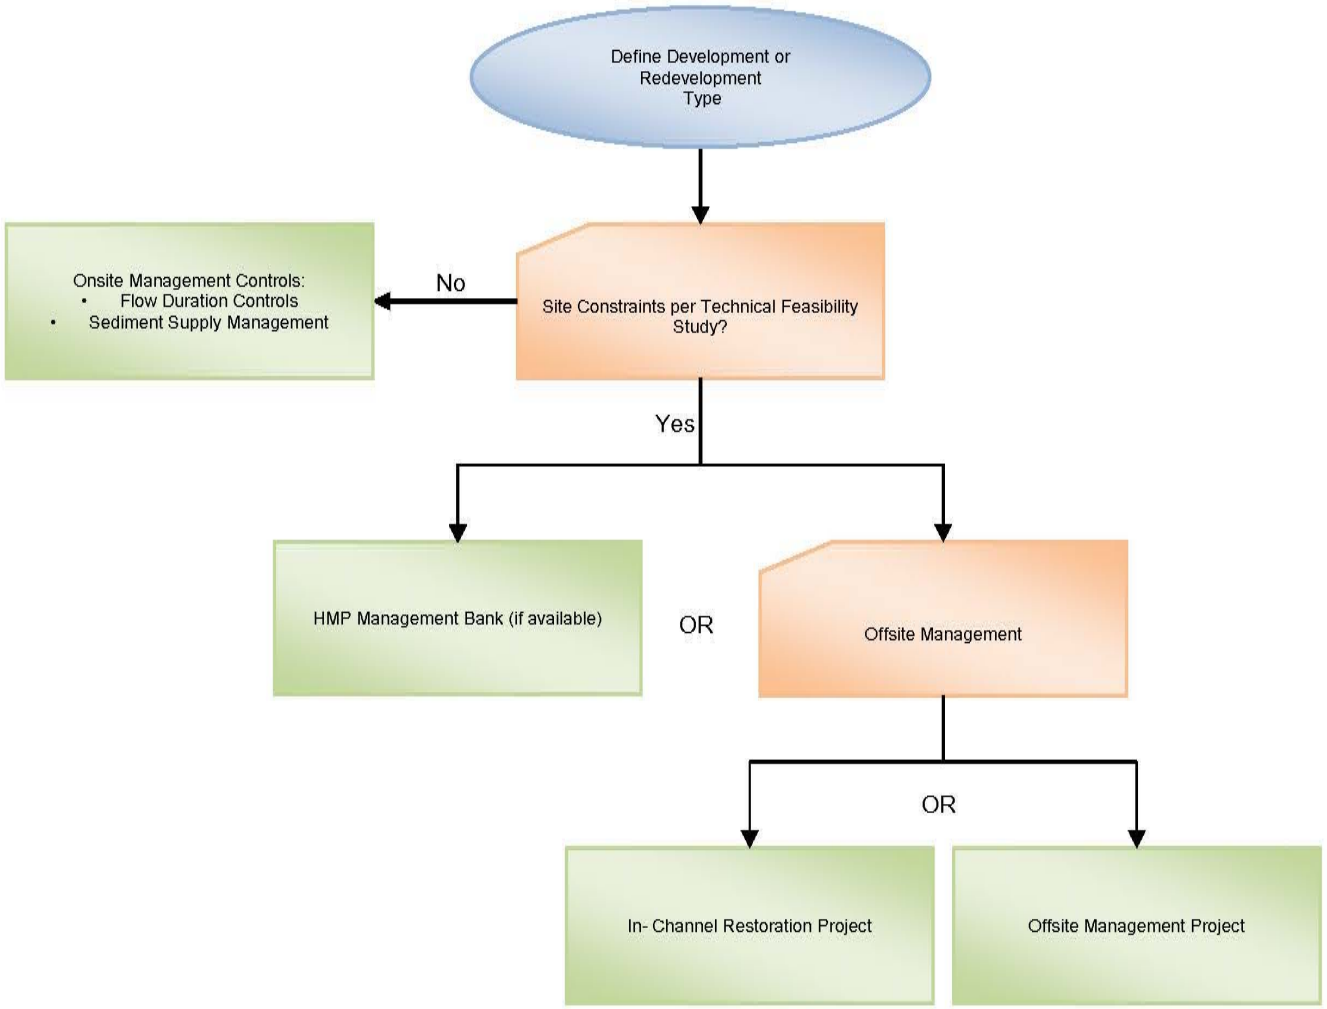
This HMP offers an alternate Hydrologic Performance Standard to those PDPs that are unable to implement flow duration matching onsite and offsite, only if the infeasibility is demonstrated and documented to the Copermittee with jurisdiction over the project site. The alternative Hydrologic Performance Standard consists of implementing projects to restore or rehabilitate channels with historic Hydromodification that are tributary to documented low or very low Index of Biotic Integrity scores. The performance equivalency of a restoration or rehabilitation project must be demonstrated to the Copermittee.

PDPs that either fail to meet both the Hydrologic Performance Standard and the Sediment Supply Performance Standard OR that do not qualify for the Alternate Performance Standard are required to redesign the project.

2.2 Meeting the Hydrologic Performance Standard

The User should consider the full suite of Hydrologic Control BMPs to manage runoff from the post-development condition and meet the Hydrologic Performance Standard identified in this section. The intent of the HMP is not to specify the types of Hydrologic Control BMPs that can be used but rather identify the criteria that must be met, allowing flexibility for PDPs to use the full suite of BMPs to meet the Hydrologic Performance Standard. The User may consider the following in identifying the Hydrologic Control BMPs for incorporation in the design of the PDP:

- LID principles as defined in Section 3.2. of the SMR WQMP;
- Structural LID BMPs that may be modified or enlarged, if necessary, beyond the Design Capture Volume (DCV)
- Structural Hydrologic Control BMPs are distinct from the LID BMPs. The LID BMP Design Handbook provides information not only on Hydrologic Control BMP design, but also on BMP design to meet the combined LID and Hydromodification requirements. The handbook specifies the type of BMPs that can be used to meet the Hydrologic Performance Standard.



LID principles, structural LID BMPs, and structural Hydrologic Control BMPs can each be modeled in the SMRHM. SMRHM has been developed as the primary tool to assist the User in selecting and sizing Hydrologic Control BMPs. SMRHM can be used by the User not only to meet the Hydrologic Performance Standard, but also to meet the LID requirements. SMRHM incorporates additional BMPs that may be investigated by the User. For example, buffer zones for those PDPs adjacent to channels can be modeled and sized the meet the Hydrologic Performance Standard. The User may refer to the SMRHM User Guidance Manual in APPENDIX G for further details on the BMPs available to meet the Hydrologic Performance Standard.

For some PDPs, implementation of onsite Hydrologic Control BMPs consistent with the HMP may not be feasible due to site constraints. There are two Alternative Compliance Options for PDPs that cannot implement onsite Hydrologic Control BMPs:

- Identify and construct offsite Hydrologic Control BMPs; and
- Pay into an HMP management bank, if an HMP management bank is available to the PDP.

The decision matrix that Users should follow to meet the Hydrologic Performance Standard is summarized in **Figure 2**.

Figure 2. Hydrologic Performance Standard – Decision Matrix

2.2.i Continuous Simulation Modeling

Introduction to the SMR Hydrology Model

Permit Provision F.1.h.(1)(b) identifies that the Hydrologic Performance Standard should be demonstrated based on continuous hydrologic simulation over the entire available rainfall record. As part of the HMP development, an integrated Hydrologic Control BMP sizing tool, SMRHM, has been prepared. The SMRHM has been developed to help Users comply with Hydromodification requirements. This modeling approach is different from the District's calibrated rainfall-runoff procedures and criteria for drainage design, flood control design, and hydrologic management purposes. HMP requirements specified in the 2010 SMR MS4 Permit are separate from the requirements for hydrologic management within the SMR for development effects of runoff per the District's Hydrology Manual. Specific evaluation criteria were developed for the design and analysis of Hydrologic Control BMPs using continuous simulation hydrologic modeling.

Continuous simulation modeling uses an extended time series of recorded precipitation data as input and generates hydrologic output, such as surface runoff, infiltration, and evapotranspiration, for each model time step. Continuous hydrologic models are typically run using either 1-hour or 15-minute time steps. Based on a review of available rainfall records in the SMR, the SMRHM uses 15-minute time series of rainfall data. Continuous models generate model output for each time step. In this case, hydrologic output is generated at each time step (15 minutes) of the continuous model.

Use of the continuous modeling approach allows for the estimation of the frequency and duration by which flows exceed the significant flow range (with a lower flow threshold adopted as 10% of the 2-year flow for this plan, and an upper flow valued adopted as 100% of the 10-year flow for this plan, which is considered the significant flow range). The limitations to increases of the frequency and duration of flows within that geomorphically significant flow range represent the key component to the SMR approach to Hydromodification management.

The SMRHM, along with a SMRHM Guidance Document explaining how to operate the model, is made available to all Users at no cost. The SMRHM is the only software that is approved by the Copermittees. However, the User may opt to develop its own model using publicly-available software, which performs continuous hydrologic simulations over the available period of rainfall record (over 30 years). The use of a different model than the SMRHM is subject to prior approval by the Copermittee with jurisdiction over the project site. The following public domain software models may be used:

- Hydrologic Simulation Program – FORTRAN (HSPF), distributed by the United States Environmental Protection Agency (USEPA)
- Hydrologic Engineering Center – Hydrologic Modeling System (HEC-HMS), distributed by the USACE Hydrologic Engineering Center
- Stormwater Management Model (SWMM); distributed by USEPA

Peak Flow and Duration Statistics

To assess the effectiveness of Hydrologic Control BMPs to meet the Hydrologic Performance Standard, peak flow frequency statistics are required. Peak flow frequency statistics estimate how often flow rates exceed a given threshold. In this case, the key peak flow frequency values are the lower and upper bounds of the geomorphically significant flow range. Peak flow frequency statistics can be developed using either a partial-duration or peak annual series. Partial-duration series frequency calculations consider multiple storm events in a given year while the peak annual series considers just the peak annual storm event.

Flow duration statistics are also summarized to determine how often a particular flow rate is exceeded. To determine if a Hydrologic Control BMP meets the Hydrologic Performance Standard, peak flow frequency and flow duration curves are generated for the pre-development (naturally occurring) condition and the post-project condition. Both pre-development and post-project simulation runs are extended for the entire length of the rainfall record.

The need for partial-duration statistics is more pronounced for Hydrologic Performance Standards based on more frequent return intervals (such as the 2-year runoff event), since the peak annual series does not perform as well in the estimation of such events due to the bimodal nature of the precipitation in Southern California (few wet years with many events, many dry years with few events). This problem is especially pronounced in the SMRs semi-arid climate. After a review of supporting literature, the use of a partial-duration series is recommended for semi-arid climates similar to the climate in the SMR, where prolonged dry periods can skew peak flow frequency results determined by a peak annual series for more frequent runoff events.

For the statistical analysis of the rainfall record, partial duration series events have been separated into discrete unrelated rainfall events assuming the following criteria.

1. A minimum interval of 24 hours between peaks is applied to capture those peaks generated from back-to-back storms.
2. The Weibull plotting method is used to rank the selected peaks by the partial duration method as this method is the most adequate for statistical analysis of Southern California channels, in which wet-weather and dry-weather years produce two populations of flood events.

Rainfall Data

The SMRHM integrates local rainfall data to design Hydrologic Control BMPs. To provide for clear climatic distinction between the Temecula Valley, the western plateau, the northern valley, and the eastern slopes of the SMR, historical records for a series of three rainfall data stations located within or in close proximity to the SMR were compiled, formatted, modulated, and quality controlled for analysis.

Long-term rainfall records of 15-minute intervals have been prepared and made available by the District for these three rainfall stations. The District operates and maintains several rainfall stations, which feed into the Riverside County Automated Local Evaluation in Real Time

(ALERT) telemetry system rain gauges, the California Climatic Data Archive, National Oceanic and Atmospheric Administration (NOAA), the National Climatic Data Center, and the Western Regional Climate Center. For the selected three stations, the length of the overall rainfall station record is a minimum of 37 years.

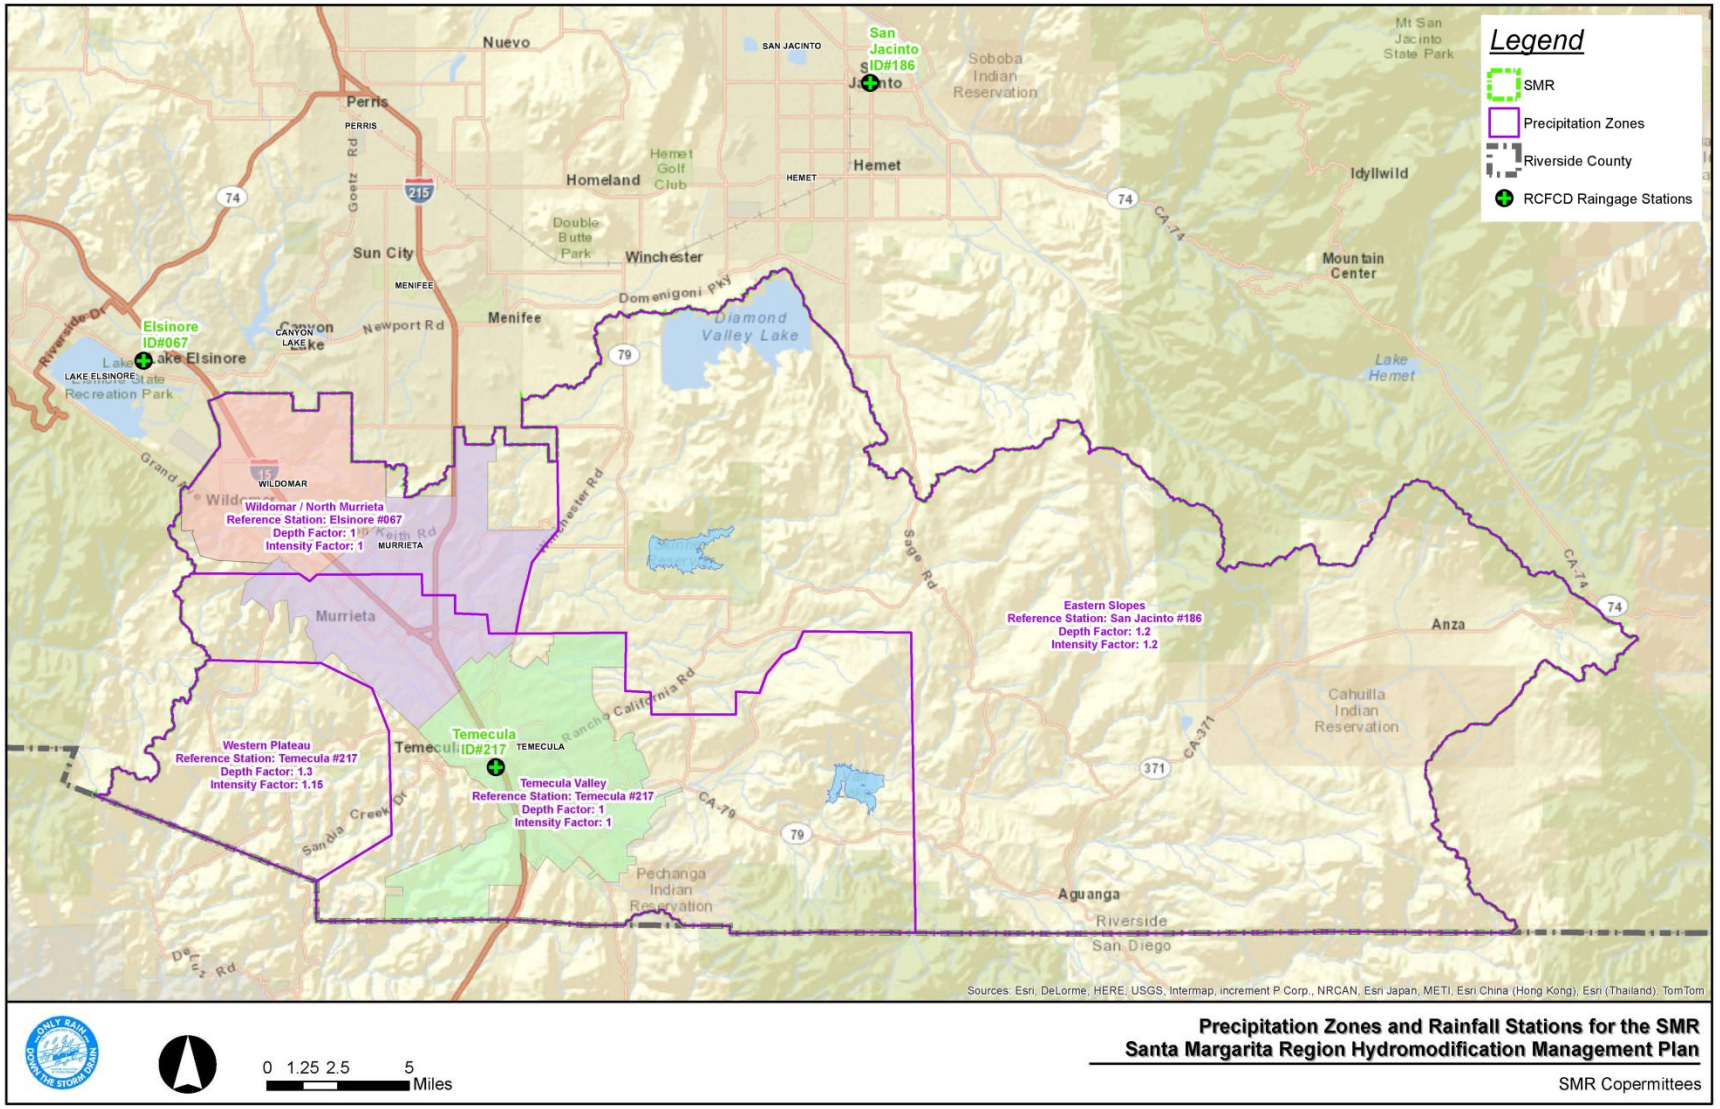
Gauge selection was further governed by minimum continuous simulation modeling requirements, including the following:

- The selected precipitation gauge data set should exhibit similar meteorological and rainfall trends, especially in terms of intensity and total precipitation depth, to ensure that long-term rainfall records are similar to the anticipated rainfall patterns for the project site. When available, gauges were selected near areas planned for future development and redevelopment.
- Reporting frequency for the gauge data set should be at least hourly, if not at a 15-minute interval. Most of the rainfall stations operated by the District report precipitation in real-time.
- The gauge rainfall data set should extend for the entire length of the record, with a minimum of 37 years.
- Use of the most applicable long-term rainfall gauge data, along with regional scaling of rainfall patterns from a reference station, is required to account for the diverse rainfall patterns across the SMR.

Four meteorological zones were identified and delineated from the rainfall patterns observed from NOAA Atlas 14 precipitation-frequency maps, isohyetal maps from the District's Hydrology Manual (1978), and the professional knowledge of the District's Hydrologic Data Collection Section. Only three precipitation stations were identified as viable for the purpose of continuous simulation because of the available length of precipitation records. Out of the three stations, only one station (Temecula, ID#217) is located within the SMR; the two other stations, Elsinore (ID#067) and San Jacinto (ID#186), are located in close proximity to the SMR. The four meteorological zones are: the Western Plateau covering the Santa Rosa Plateau area, the Temecula Valley, the Wildomar/North Murrieta area, and the Eastern Slopes covering the eastern part of the SMR. For each meteorological zone, a correction factor, which accounts for the variations in depths and intensity observed on the isohyetal maps, is applied independently to the associated precipitation records. The location of the three selected rain gauge stations and the delineation of the four meteorological zones are shown in **Figure 3**.

Table 1 lists the meteorological zones and the associated rainfall stations. In addition, the period of available record is presented.

Table 1 - SMR Meteorological Zones & Associated Rainfall Stations



Meteorological Zone	Station	15-minute data span
Western Plateau	Temecula (ID#217)	January 1974 – July 2012
Wildomar/North Murrieta	Elsinore (ID#067)	January 1940 – July 2012
Temecula Valley	Temecula (ID#217)	January 1974 – July 2012
Eastern Slopes	San Jacinto (ID#186)	January 1940 – July 2012

All the presented factors have been considered in the selection of the appropriate rainfall data set before inclusion into the SMRHM. For a given project location, the User should refer to the rainfall station map shown in **Figure** and identify the meteorological zone where the proposed project is located. The meteorological zones are integrated in the SMRHM and the appropriate rain gauge station will be automatically selected by the model upon pinpointing the location on the model's map.

If desirable, the User is allowed to design a project-specific continuous simulation model and must comply with the factors and precipitation zones presented in this section when selecting the associated rain gauge station.

A rainfall station map associated with this HMP is presented in **Figure 3** for public use. Where possible, rainfall data sets located in the same meteorological zone as the project should be selected.

Figure 3 - Precipitation Zones and Rainfall Stations for the Santa Margarita Region

Evapotranspiration Parameters

Hydrologic Performance Standards developed as part of this HMP to control runoff peak flows and durations are based on a continuous simulation of rainfall runoff using locally derived parameters for evaporation and evapotranspiration. Known data sources for potential evapotranspiration data in proximity to the SMR are listed below.

Historical potential evapotranspiration at Elsinore station (CA042805) is considered to best represent the evapotranspiration conditions within the SMR.

Other gauging stations that record potential evapotranspiration were not selected because the period of record did not match with that of the precipitation station, or the local meteorological patterns are not representative of those observed in the SMR. The potential evapotranspiration will be coupled with historical records of temperature to determine the actual daily evapotranspiration. **Table 2** summarizes available sources for potential evapotranspiration in the SMR.

Table 2 - Available Evapotranspiration Sources

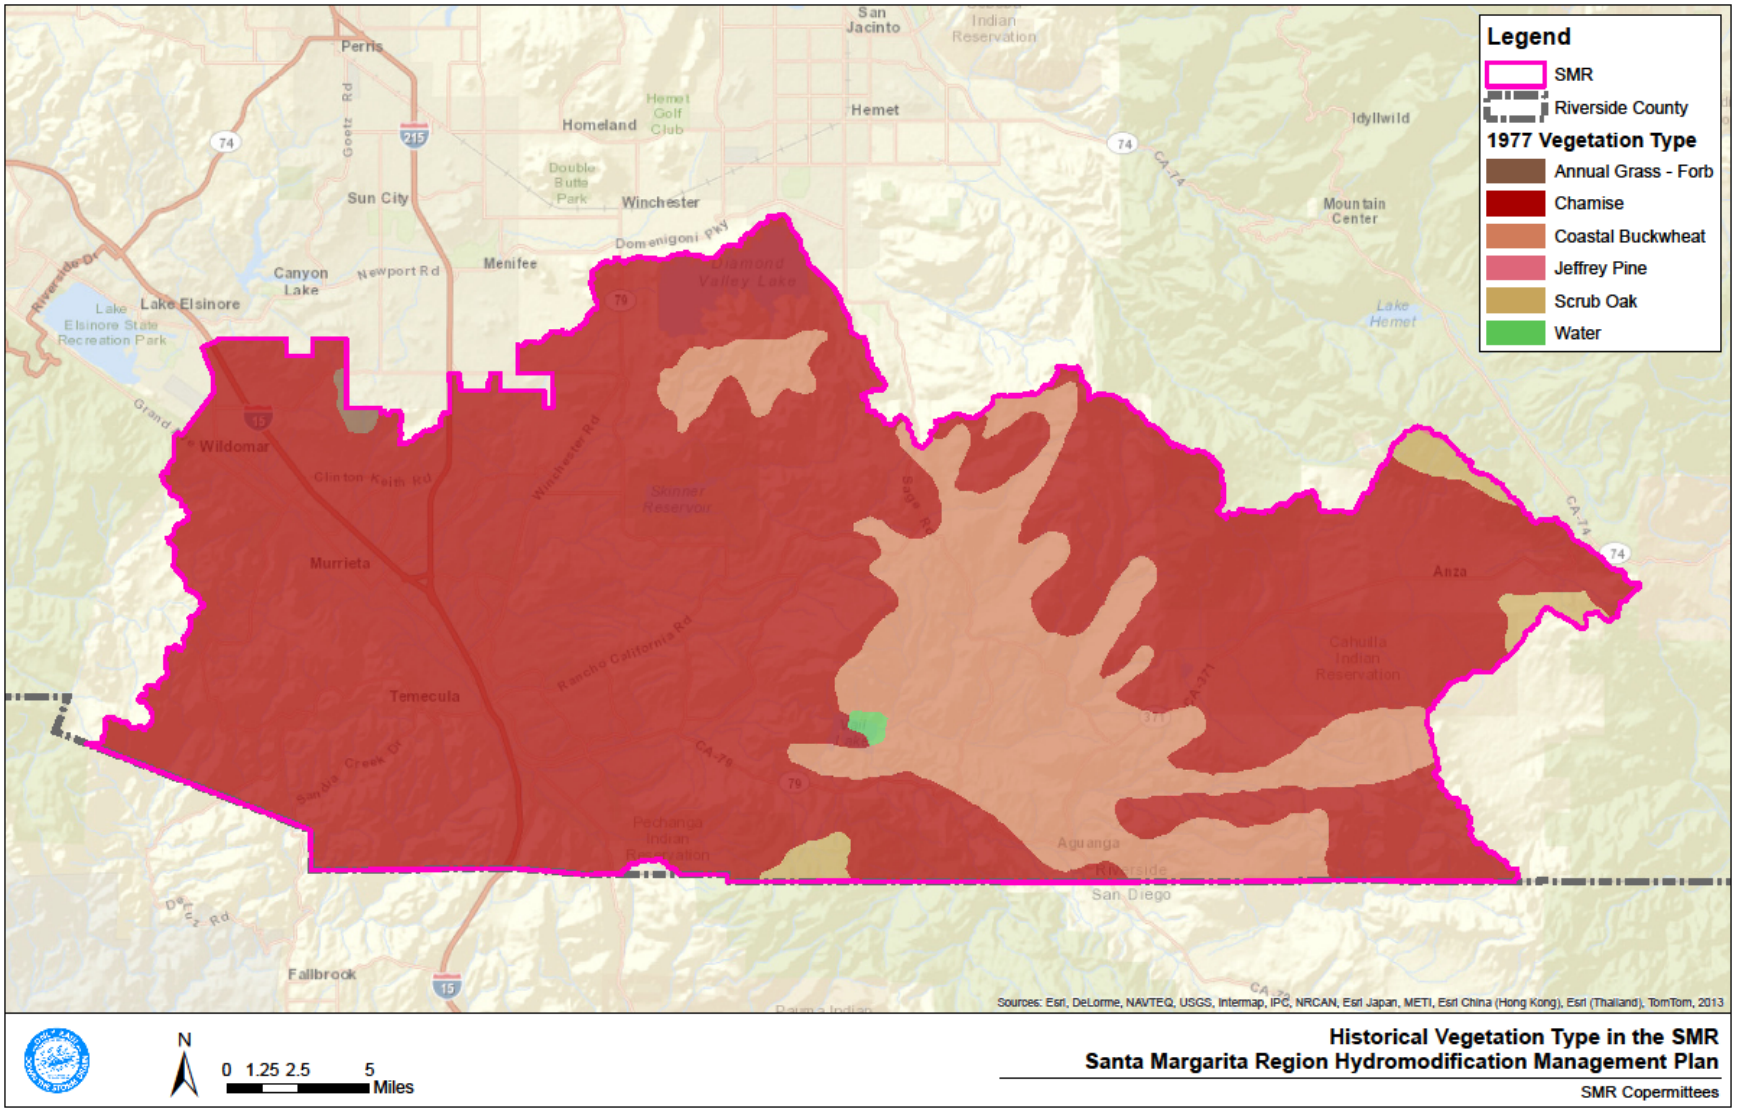
Station Name ID	Data Type	Data Source	Recording Frequency	Hourly data span
Elsinore (CA042805)	Potential Evapotranspiration	BASIN	Hourly	August 1948 – November 2005

Long-term evaporation / evapotranspiration data sets are being generated to correspond with long-term rainfall records. The final selection of rainfall loss parameters and evaporation data is part of the SMRHM development process.

In summary, the published literature reviewed as part of this study support the methods and approach taken in developing the SMR HMP.

2.2.ii Identification of naturally-occurring conditions

Section F.1.h.(d) of the 2010 SMR MS4 Permit requires that estimated post-project runoff discharge rates and durations shall not exceed pre-development (naturally occurring) discharge rates and durations. Compliance with this Permit requirement should be based on the results of continuous simulation and the use of the SMRHM or an approved equivalent model. As part of developing the supporting hydrology model for a PDP, a User must identify and document, using professional knowledge, pre-development (naturally occurring) conditions in terms of geology, topography, soils, and vegetation.



Several publicly-available information sources may help the User characterize pre-development conditions, including:

- Soil database (#678, #679, and #680) from the Natural Resources Conservation Service (NRCS). Among the parameters of interest, the database identifies the type, the original range of observed topographic slopes, the soil erosion factor K, and, if available, plant

community information for the native or pre-development soil. The database is accessible through the Web Soil Survey page (http://websoilsurvey.nrcs.usda.gov/app/HomePage.htm).

- Vegetation and ecoregional GIS information listed by the U.S. Forest Services. The USEPA Ecoregion database information locates the SMR in the Southern California Mountains and Valleys Ecoregion and references the climate of humid and temperate Mediterranean type. The USEPA Ecoregion database identifies also the vegetation province of the SMR within the California Coastal Range Open Woodland-Shrub-Coniferous Forest-Meadow province. A historical CALVEG GIS vegetation layer is available for the year 1977 (USFS, 2000). The historical vegetation layer reveals a majority of evergreen chaparral shrub and scrub oak within the watershed. For those areas located within the Urban Land and Agriculture vegetation area, the User may select the shrub vegetation for pre-development, naturally occurring, conditions. **Figure 4.** Historical Vegetation and Ecoregions in the Santa Margarita Region delineates the distribution of historical vegetation types in the SMR. GIS-based layers are available on the USFS website: (http://www.fs.usda.gov/detail/r5/landmanagement/gis/). Consistent with historical aerials, the User should select Shrub as the native vegetation, if the PDP is located in an urban/agricultural area on the 1977 CALVEG GIS layer.
- Other historical USGS topographic maps and aerial photos of Riverside County, specifically of the SMR area, are publicly available from the USGS website.

Figure 4. Historical Vegetation and Ecoregions in the Santa Margarita Region

2.2.iii Hydrologic Control BMPs

As identified in **Section 2.2.i**. PDPs are encouraged to use the full suite of Hydrologic Control BMPs available to meet the Hydrologic Performance Standards. The intent of the HMP is not to specify the types of Hydrologic Control BMPs that can be used but rather identify the criteria that must be met.

Selection and design of Hydrologic Control BMPs is an iterative process that can be facilitated using the SMRHM. The SMRHM has a comprehensive menu of site design LID BMPs and Hydrologic Control BMPs that can be selected for PDPs. The design parameters for these Hydrologic Control BMPs have been incorporated into the model and can be modified to an extent based on site constraints. The User is invited to refer to the SMRHM Guidance Document that is referenced in APPENDIX G for SMRHM specific questions.

Hydrologic Control BMPs must be maintained for optimal operation. PDPs are conditioned to provide verification of inspections and maintenance operations as defined in Section H of the SMR WQMP Template that must be completed in its entirety prior to the issuance of a grading permit. The list of such inspections and maintenance operations must be included in the WQMP for the PDP submitted by the User. Maintenance activities must ensure that the Hydrologic Control BMPs are functioning as designed.

2.2.iv Alternative Compliance Options

The use of Alternative Compliance Options will require coordination with the Copermittee with jurisdiction over the project site and may also require coordination with other Copermittee(s) with jurisdiction over an offsite location where a Hydrologic Control BMP may be proposed. For some PDPs, implementation of onsite Hydrologic Control BMPs consistent with the HMP may not be feasible due to site constraints. These projects require alternatives to onsite Hydrologic Control BMPs. There are two Alternative Compliance Options for PDPs that cannot implement onsite Hydrologic Control BMPs. One option is for the User to identify and construct offsite Hydrologic Control BMPs. The other option is for the PDP to pay into an HMP Management Bank, if an HMP Management Bank option is available.

HMP Alternative Compliance Option 1: Offsite Hydrologic Control Management

A progression through a defined process is required to document eligibility then implementation of alternative HMP compliance. Offsite Hydrologic Control management is based on completing a series of steps to meet compliance that is consistent with Section F.1.h.(3) of the 2010 SMR MS4 Permit. These steps include the following:

1. Technical feasibility study of onsite Hydrologic Control BMPs; and
2. Offsite Hydrologic Control BMP project within the same hydrologic unit as the PDP or in-channel restoration of a channel receiving runoff from the PDP.

Step 1: Conduct a technical feasibility study for onsite Hydrologic Control BMPs

A technical feasibility study is required to identify why onsite Hydrologic Control BMPs cannot be incorporated into the PDP. The technical feasibility study must include the project constraints and provide detailed technical justification as to why the project constraints prevent implementation of onsite Hydrologic Control BMPs. The technical feasibility study will be submitted to the Copermittee with jurisdiction over the project site for review as part of the Preliminary WQMP. The Copermittee must approve the findings of the technical feasibility study before the PDP moves on to Step 2.

The Hydrologic Control BMP technical feasibility study will be incorporated into the SMR WQMP Template and integrated with the LID feasibility analysis; however, it should be noted that the criteria for Hydrologic Control BMP and LID requirements are different. The feasibility analysis for both Hydrologic Control BMPs and LID will be integrated into one feasibility study for the PDP and submitted with the Preliminary WQMP.

The technical feasibility study should:

- Provide a narrative regarding the applicability of LID principles onsite as required by the SMR WQMP;
- Evaluate the feasibility of infiltration to capture partially or in its entirety the DCV based on the presence of either low infiltrating soils or high groundwater level, proximity to a water well or a contaminated plume, or a geotechnical report precluding effective and safe infiltration;
- Evaluate the feasibility of harvest-and-use BMPs based on local water demands;
- Evaluate the feasibility of implementing detention or retention BMPs onsite based on critical geotechnical considerations such as collapsible soil, expansive soil, slopes, liquefaction and other factors identified by a registered Geotechnical Engineer. The feasibility to implement Hydrologic Control BMPs and meet the Hydrologic Performance Standard onsite may be principally dictated by the geotechnical considerations.

Step 2: Implement offsite Hydrologic Control BMP projects within the same channel system as the PDP (2a) or implement in-channel restoration or rehabilitation of the PDP receiving water (2b)

For those PDPs where the Hydrologic Control BMP technical feasibility study for onsite controls has been approved by the Copermittee with jurisdiction over the project site, step 2 is to either (a) implement an offsite Hydrologic Control BMP project within the same channel system as the PDP, or (b) implement an in-channel restoration project for the channel receiving runoff from the PDP. The process for these options under Step 2 is detailed below:

HMP Alternative Compliance Option 1 – Step 2a: Implement Offsite Hydrologic Control Project within the Channel System receiving runoff from the PDP

In choosing this option, the PDP must investigate potential locations for implementation of an offsite Hydrologic Control project within the channel system receiving runoff from the PDP. If the User demonstrates that an offsite Hydrologic Control project is not feasible in the channel system receiving runoff from the PDP, then an offsite Hydrologic Control project in the same hydrologic unit as the PDP may be approved. The offsite Hydrologic Control project must manage the incremental impact from not achieving the pre-development (naturally occurring) runoff flow rates and durations for the project site. Sizing of offsite Hydrologic Control projects may be accomplished using the SMRHM. The User will evaluate and identify potential sites in the channel system receiving runoff from the PDP, and if not feasible, then evaluate projects in the same hydrologic unit for implementation of an offsite Hydrologic Control project that has the capacity to provide the PDPs Hydrologic Performance Standard requirements. If an Adequate Sump is identified in the channel system receiving runoff from the PDP, the User will submit a report detailing:

- That the offsite Hydrologic Control project manages the incremental impact from the pre-development (naturally occurring) runoff flow rates and durations for the project site;
- Conceptual plans for the offsite Hydrologic Control project as part of an amended WQMP for review and approval;
- If the PDP is a redevelopment project, that the post-project runoff flow rates and durations do not exceed pre-project runoff flow rates and durations; and
- If no potential offsite Hydrologic Control project sites are identified in the channel system receiving runoff from the PDP, that there is an offsite Hydrologic Control project in the same hydrologic unit.

If no potential offsite Hydrologic Control project sites are identified in the same hydrologic unit as the PDP, the PDP must implement Option 2(b), a restoration or rehabilitation project in the channel system with historic Hydromodification and receiving runoff from the PDP.

HMP Alternative Compliance Option 1 – Step 2b: Implement In-Channel Restoration or Rehabilitation of the Channel Receiving Runoff from the PDP

In choosing this option, the PDP investigates the potential for implementation of an in-channel restoration or rehabilitation project for the channel receiving runoff from the PDP. It must be determined that the channel receiving runoff from the PDP has experienced historic Hydromodification. The in-channel restoration or rehabilitation project must be located in the channel receiving runoff from the PDP. The PDP must submit a report detailing the historic Hydromodification, as well as conceptual plans for the in-channel restoration or rehabilitation project to the Copermittee with jurisdiction over the project site for review. The Copermittee is responsible for ensuring that the level of restoration or rehabilitation is adequate given the potential Hydromodification impacts of the PDP. Copermittees maintain individual processes

consistent with their approval procedures to ensure that the User's obligations under the HMP alternative compliance process are completed prior to approval of the PDP.

Once the project conceptual plans have been approved by the Copermittee with jurisdiction over the project site, the User must submit required permit applications to the appropriate regulatory agencies (e.g., SDRWQCB, California Department of Fish and Wildlife, USACE) for review and approval. If the PDP identifies no opportunities for in-channel restoration or rehabilitation in the channel receiving runoff from the PDP, then the PDP must implement Option 2(a), an offsite Hydrologic Control project within the same hydrologic unit as the PDP.

HMP Alternative Compliance Option 2: HMP Management Bank Alternative Compliance Option

(Note: Option 2 is available only if an HMP management bank has been developed and is available to the PDP.)

The Copermittees have the option to develop an HMP Management Bank or multiple HMP Management Banks. A HMP Management Bank will develop regional HMP management projects where PDPs can buy HMP management credits if it is determined that implementing onsite Hydrologic Control BMPs is infeasible. The development and operation of an HMP Management Bank will include the identification of potential regional Hydrologic Control projects; the planning, design, permitting, construction, and maintenance of regional Hydrologic Control projects; the development of a fee structure for PDPs participating in the HMP Management Bank; and managing the HMP Management Bank fund. Regional Hydrologic Control projects can also serve as projects for an LID waiver program if site conditions allow for implementation of LID-type projects.

If PDPs are unable to meet the Hydrologic Performance Standard by incorporating onsite Hydrologic Control BMPs, and a HMP Management Bank is available, the PDP can apply to participate in the Bank. The application must include a technical feasibility study to identify why onsite Hydrologic Control BMPs cannot be incorporated into the PDP. The technical feasibility study must include the project constraints and detailed technical justification as to why the project constraints prevent implementation of onsite Hydrologic Control BMPs. The technical feasibility study will be submitted to the Copermittee with jurisdiction over the project site for review as part of the Preliminary WQMP. The Copermittee must approve the Hydrologic Control BMP technical feasibility study for the PDP to participate in a HMP Management Bank.

2.3 Meeting the Sediment Supply Performance Standard

Bed Sediment Supply from PDPs plays a role in the stability of alluvial channels. As identified in APPENDIX C , a change in Bed Sediment Load may cause instability in the receiving channel manifested through general scour or aggradation. Lateral bank migration may also result from changes in Bed Sediment Load as the channel slope increases or decreases.

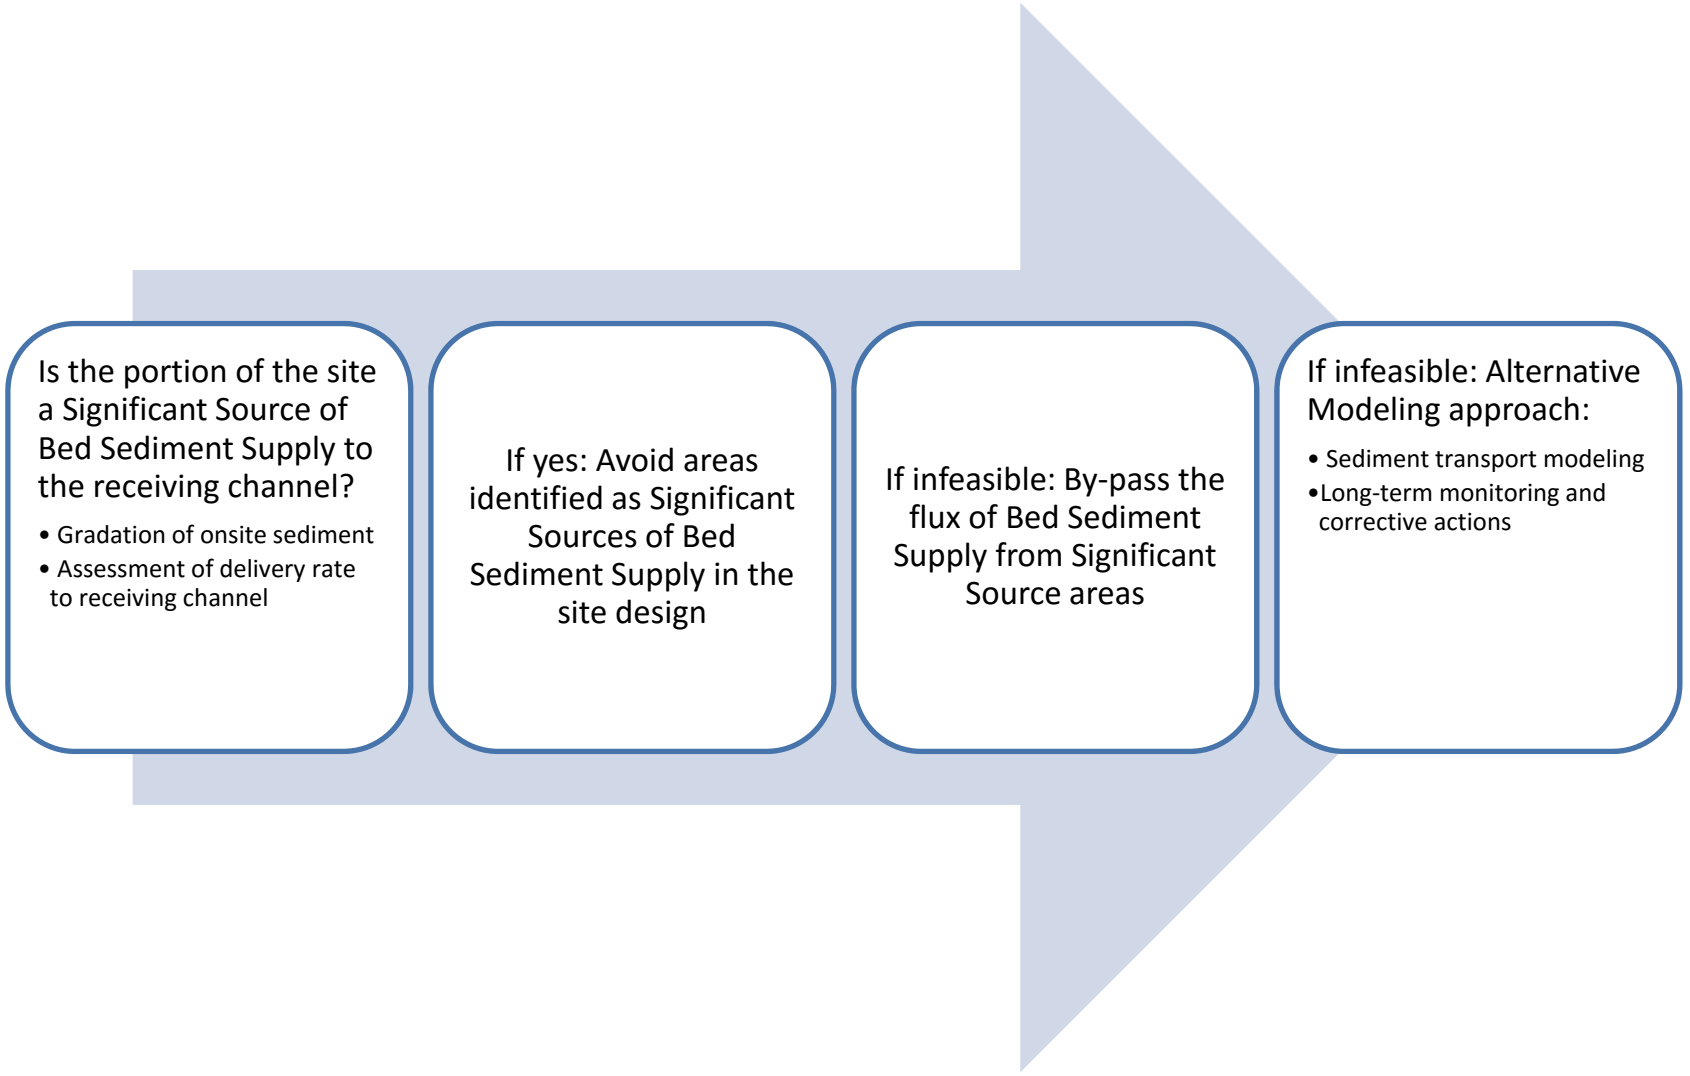
Bed Sediment typically includes coarse sand (1-2 mm) and thicker sediment sizes. The User may refer to the classification table (Table 14 of APPENDIX I) for a full listing of sediment sizes and associated critical shear stresses.

Bed Sediment Supply to a receiving channel during construction may increase as land surface is cleared and the potential for erosion is increased. Once the land surface is urbanized, the potential for Bed Sediment Supply may be reduced as compared to the pre-development condition. The purpose of this portion of the HMP is to maintain the pre-development supply of Bed Sediment to receiving channels following urban development. Total Sediment Load consists of the Bed Sediment Load that includes both material moving along the bed by rolling, sliding or Saltation) and coarse sand (1-2 mm) that is transported in near-suspension by the velocity of flow, and the Wash Load that includes clays, silts and fine sand (under 1 mm). Bed Sediment Load is a primary variable controlling channel morphology. Wash Load is the portion of the total sediment load carried continuously in suspension by the flow. Changes in Wash Load are not likely to significantly affect the channel stability, and reductions in Wash Load are generally assumed to improve habitat function.

The resiliency of channels to forestall changes due to urban development varies with the magnitude of the change and characteristics of the channel (bed and bank sediment, vegetation, channel cross-section and slope). It is difficult to quantitatively predict the response in a channel receiving runoff from urban development to changes in the fundamental variables described by Lane (1955) of discharge, Bed Sediment grain size, channel slope and Bed Sediment Load. Accordingly, the most effective approach to ensuring channel stability may be to avoid changes in the fundamental variables (Lane's interrelationship) during urban development through the implementation of channel management guidelines. In the case of Bed Sediment Load, this will be accomplished by avoiding development in areas that are a Significant Source of Bed Sediment Supply to a channel. The User must identify the areas on the project site that are a Significant Source of Bed Sediment Supply. The determination will be performed following the three-step process, as described in **Section 2.3.i**.

The general approach to ensure maintenance of the pre-project Bed Sediment Supply is a three-step process:

1. Determine whether the portion of the site is a Significant Source of Bed Sediment Load to the channel receiving runoff from the PDP.
2. Avoid areas identified as Significant Sources of Bed Sediment Supply in the PDP design.
3. Site-specific alternative compliance measures.



In the event of a projected reduction in Bed Sediment Supply, the User must investigate the feasibility of Sediment Supply BMPs, including bypassing the flux of Bed Sediment Supply from Significant Source areas onsite, otherwise maintaining pre-project Bed Sediment Supply from the site, or providing additional management of site runoff to accommodate the reduced Bed Sediment Supply. Specific guidance on sediment management measures will be provided in the SMR WQMP Template. Specifically, the SMR WQMP Template includes a Section for performing a Bed Sediment Supply assessment, which:

- Identifies the conditions for exemption from the Sediment Supply Performance Standard, if any;
- Summarizes the results of the three-step approach and identifies, for each step, the documentation required for approval of the evaluation by the Copermittee with jurisdiction over the project site. Documentation may include:
    - Results from the geotechnical and sieve analysis, the soil erodibility factor, a description of the topographic relief of the project area, and the lithology of onsite soils;
    - Results from the analyses of the sediment delivery potential to the channel receiving runoff from the project site, including the sediment source, the distance to the receiving channel, the onsite channel density, the PDP watershed area, the slope, length, land use, and rainfall intensity;
    - Quantification of the bank stability investigation, including the degree of incision, a gradation of the Bed Sediment, and identification if the receiving channel is sediment supply-limited.
- Provides a site map that identifies all onsite channels and highlights those that were identified as a Significant Source of Bed Sediment Supply. The site map must demonstrate if feasible, that the site design avoids those project site channels that may be a Significant Source of Bed Sediment Supply. In addition, the User must describe the characteristics of each channel on the project site identified as a Significant Source of Bed Sediment Supply. If the design plan cannot avoid the channels on the project site, the User should provide a rationale for each channel individually.

An Alternative Compliance Option allows the User to model the site conditions and the channel receiving runoff from the project site and provide additional management of site runoff to compensate for the reduction (or addition) of Bed Sediment Load. This option may only be used if the general approach outlined above is deemed infeasible by the Copermittee with jurisdiction over the project site, or if the project site design requires significant alteration of channel(s) on the project site. Step 1 of the three-step approach describes how channels on the project site should be identified and characterized by the User.

The stepwise approach that Users should follow to meet the Sediment Supply Performance Standard is summarized in **Figure 5**.

Figure 5 - Sediment Supply Performance Standard – Stepwise Approach

2.3.i Three-Step Process

The User must determine the location of the alluvial channel receiving runoff from the project site. The first such channel that is unlined (invert, side slopes or both) will serve as the "assessment" or "receiving" channel for the PDP. The following methodology will be used to ensure that the PDP does not adversely impact the delivery of Bed Sediment Supply to the assessment channel.

Step 1: Determine whether the Portion of the Project Site is a Significant Source of Bed Sediment Supply to the Channel Receiving Runoff

A triad approach will be completed to determine whether the project site is a Significant Source of Bed Sediment Supply to the channel receiving runoff and includes the following components:

A. Site soil assessment, including an analysis and comparison of the Bed Sediment in the receiving channel and the onsite channel;

B. Determination of the capability of the channels on the project site to deliver the site Bed Sediment (if present) to the receiving channel; and

C. Present and potential future condition of the receiving channel.

Prior to performing a site-specific triad assessment, the User should refer to the macro-scale findings of the HRU/GLU Analysis performed as part of the SMR Hydromodification Susceptibility Study (APPENDIX D). The HRU/GLU Analysis will provide the designer with critical geomorphic information for the subwatershed where the PDP is located, including the impacts of existing imperviousness on the hydrologic cycle and the potential for sediment production.

A. Site soil assessment, including an analysis and comparison of the Bed Sediment in the channel receiving runoff and the onsite channels

A geotechnical and sieve analysis is the first piece of information to be used in a triad approach to determine if the project site is a Significant Source of Bed Sediment Supply to the assessment channel. An investigation must be completed of the assessment channel to complete a sieve analysis of the Bed Sediment. Two samples will be taken of the assessment channel using the "reach" approach (TS13A, 2007). Samples in each of the two locations should be taken using the surface and subsurface bulk sample technique (TS13A, 2007) for a total of four samples. Pebble counts may be required for some channels.

A similar sampling assessment should be conducted on the project site. First-order and greater channels that may be impacted by the PDP (drainage area changed, stabilized, lined or replaced with underground conduits) will be analyzed in each subwatershed. First-order channels are identified as the unbranched channels that drain from headwater areas and develop in the uppermost topographic depressions, where two or more contour crenulations (notches or

indentations) align and point upslope (NEH, 2007). First-order channels may, in fact, be field ditches, gullies, or ephemeral gullies (NEH, 2007). One channel per subwatershed that may be impacted on the project site must be assessed. A subwatershed is defined as tributary to a single discharge point at the project site boundary.

The sieve analysis should report the coarsest 90% (by weight) of the sediment for comparison between the site and the assessment channel. The User should render an opinion if the Bed Sediment found on the site is of similar gradation to the Bed Sediment found in the receiving channel. The opinion will be based on the following information:

- Sieve analysis results
- Soil erodibility (K) factor
- Topographic relief of the project area
- Lithology of the soils on the project site

The User should rate the similarity of onsite Bed Sediment and Bed Sediment collected in the receiving channel as high, medium, or low. The rating should be consistent with Figures 4 through 6 of the Hydromodification Susceptibility Report and Mapping: SMR (See APPENDIX D). This site soil assessment serves as the first piece of information for the triad approach.

B. Determination of the capability of the onsite channels to deliver Bed Sediment Supply (if present) to the channel receiving runoff from the project site.

The second piece of information is to qualitatively assess the sediment delivery potential of the channels on the project site to deliver the Bed Sediment Supply to the channel receiving runoff from the project site, or the Bed Sediment delivery potential or ratio. There are few documented procedures to estimate the Bed Sediment delivery ratio (see: Williams, J. R., 1977: Sediment delivery ratios determined with sediment and runoff models. IAHS Publication (122): 168-179, as an example); it is affected by a number of factors, including the sediment source, proximity to the receiving channel, onsite channel density, project sub-watershed area, slope, length, land use and land cover, and rainfall intensity. The User will qualitatively assess the Bed Sediment delivery potential and rate the potential as high, medium, or low.

C. Present and potential future condition of the channel receiving runoff from the project site.

The final piece of information is the present and potential future condition of the channel receiving runoff from the project site. The User should assess the receiving channel for the following:

- Bank stability - Receiving channels with unstable banks may be more sensitive to changes in Bed Sediment Load.

- Degree of incision - Receiving channels with moderate to high incision may be more sensitive to changes in Bed Sediment Load.
- Bed Sediment gradation - Receiving channels with more coarse Bed Sediment (such as gravel) are better able to buffer change in Bed Sediment Load as compared to beds with finer gradation of Bed Sediment (sand).
- Transport vs. supply limited channels. Receiving channels that are transport limited may be better able to buffer changes in Bed Sediment Load as compared to channels that are supply limited.

The User will qualitatively assess the channel receiving runoff from the project site using the gathered observations and rate the potential for adverse response based on a change in Bed Sediment Load as high, medium, or low.

In addition to the findings of the macro-scale HRU/GLU Analysis, the User should use the triad assessment approach, weighting each of the components based on professional judgment to determine if the project site provides a Significant Source of Bed Sediment Supply to the receiving channel, and the impact the PDP would have on the receiving channel. The final assessment and recommendation must be documented in the HMP portion of the WQMP.

The recommendation may be any of the following:

- Site is a Significant Source of Bed Sediment Supply – all channels on the project site must be preserved or by-passed within the site plan.
- Site is a source of Bed Sediment Supply – some of the channels on the project site must be preserved (with identified channels noted).
- Site is not a Significant Source of Bed Sediment Supply.

The final recommendation will be guided by the triad assessment. Projects with predominantly "high" values for each of the three assessment areas would indicate preservation of channels on the project site. Sites with predominantly "medium" values may warrant preservation of some of the channels on the project site, and sites with generally "low" values would not require site design considerations for Bed Sediment Load.

The User should also assess if the receiving channel has been altered either for alignment, cross section, or longitudinal grade, or has degraded to the extent that an in-channel restoration or rehabilitation project would be required to restore the functions and values of the channel bed. In such cases, the User should discuss options for participating in an in-channel project in lieu of onsite design features to preserve the Bed Sediment Supply.

Step 2: Avoid Areas Identified As Significant Sources of Bed Sediment Supply in the Site Design

If the analysis in Step 1 indicates that some or all of the channels on the project site must be preserved as a source of Bed Sediment Supply to the receiving channel, the site plan should be

developed to avoid impacting the identified channels. The User will designate channels on the project site that should be avoided to preserve the discharge of Bed Sediment Supply from the site. The User may consider the factors discussed above when determining whether a specific channel on the project site is a Significant Source of Bed Sediment Supply and should be preserved.

Step 3: Site-Specific Alternative Compliance Measures

If it is infeasible to avoid channels on the project site that are Significant Sources of Bed Sediment Supply in the design of the site plan, the drainage(s) may be by-passed to maintain the Bed Sediment Supply to the receiving channel. The User will need to prepare specific designs to achieve this objective.

2.3.ii Alternative Compliance Option

An Alternative Compliance Option may only be pursued if the replacement of Bed Sediment Supply is deemed infeasible by the Copermittee with jurisdiction over the project site, or if the project site design requires significant alteration of onsite channels. The infeasibility of the different Sediment Supply BMPs stated in the general approach may only be demonstrated and documented by the User. The User may also demonstrate the expected feasibility of the Alternative Compliance Option.

In such an eventuality, Users may propose an Alternative Compliance Option for Bed Sediment management from a PDP based on numerical modeling. This option would generally include a long-term monitoring program, with potential corrective measures to be identified and implemented as needed in response to findings from the monitoring program. The use of an Alternative Compliance Option derives from Lane's interrelationship that conceptualizes the balance between hydrologic and geomorphic processes for alluvial channels.

For example, the User may recommend an annual replenishment of Bed Sediment Load downstream of the project site based on an estimation of the amount of reduction of Bed Sediment Supply from the project site as a result of development.

The general steps to estimate the average annual replacement of Bed Sediment Load are:

1. Identify the sources of Total Sediment Supply based on a geotechnical review of the site. Areas that are not a Significant Source of Bed Sediment Supply may be omitted from the analysis.
2. Estimate the base erosion rate of areas identified as sources of Total Sediment Supply. This estimate should be completed using the Modified Universal Soil Loss Equation (MUSLE) and a 2-year runoff return period.
3. Approximate the sediment delivery ratio of sources. This can be done using published values for the area or estimated values based on best professional judgment.
4. Evaluate the Bed Sediment proportion of sources and calculate the yield rate. The Bed Sediment proportion of the sources should be determined by comparing the sieve analysis

in the channel with that in the identified supply areas on the project site. The yield is computed by multiplying the total yield, by the Bed Sediment proportion and the sediment delivery ratio.

5. Identity sources of Bed Sediment Supply to be eliminated after development. This is performed based on a review of the site plan.
6. Calculate and compare the total pre- and post-development Bed Sediment Supply yield to estimate the average annual amount of Bed Sediment that should be replenished to the channel.

Alternatively, the User may propose adjusting the flow duration curve to maintain pre-project conditions in the receiving channel with the expected change in Bed Sediment Supply discharge from the project site. The erosion potential (total sediment transported in the proposed condition vs. the baseline) should be modeled and used to adjust the flow duration curve to ensure a condition that does not vary more than 10% from the natural condition. Bledsoe (2002) introduced the index of stream erosion potential (Ep), which compares the erosive power of pre- and post-development streamflows. This index allows comparison of sediment-transport relationships to ensure that an erosion potential that is comparable to pre-development conditions is achieved. Changes in Total Sediment Supply after development are accounted for by changing the target Ep from 1.0 (proposed is the same as pre-project) in proportion to the change in Bed Sediment Supply (post-development/pre-development), calculated using the six steps above. This option may not be practical when changes in Bed Sediment Supply are relatively large (greater than 50%). The User should determine, using best professional judgment, if the alternative modeling approach is applicable.

The alternative modeling approach must include the following:

1. Continuous hydrologic simulation for the project baseline condition and proposed condition over the range of flow values up to the pre-project 10-year event;
2. Sediment transport model of the receiving channel for the PDP baseline condition and proposed condition;
3. Analysis of the change in Bed Sediment Supply from the PDP baseline condition to the proposed condition;
4. Explanation of method used to control the discharge from the PDP to account for changes in the delivered Bed Sediment Supply; and
5. Summary report.

Channel systems and fluvial processes react to changes in the watershed as to progressively evolve to a dynamic equilibrium. However, the SMR is geomorphically highly dynamic due to natural conditions including topography, vegetative cover and soils, and may only achieve dynamic equilibrium in geologic time (i.e., many thousands of years). The alternative Hydrologic Performance Standard for this option consists of evaluating the changes in both Bed Sediment Supply and hydrologic changes caused by a PDP. The User must demonstrate through a channel stability impact assessment that the changes to both the amount of Bed Sediment Load being transported and the amount of sediment supplied to the receiving channel will maintain the

general trends of aggradation and degradation in the different impacted channel reaches, which are representative of the pre-development geormorphologic state of a channel. Typical channel sediment continuity analysis procedures may be performed using moveable bed fluvial models such as HEC-6t or equivalent.

Receiving channel monitoring may be required for the project site to verify that the PDP does not result in long-term changes to the receiving channel. The User should make a recommendation if long-term monitoring is required, for concurrence by the Copermittee with jurisdiction over the project site. Some of the considerations in assessing the need for a long-term monitoring program are:

1. Total area of the watershed at the PDP discharge point vs. the PDP area;
2. Condition and type of receiving channel;
3. Magnitude of change in Bed Sediment Supply to the receiving channel;
4. Relief of the land on the project site;
5. Number of channels (density) potentially delivering Bed Sediment Supply to the receiving channel, and the delivery ratio; and
6. Soil characteristics on the project site.

Site-specific modeling is discussed further in APPENDIX H .

2.4 Mechanisms to Assess and Address Cumulative Impacts

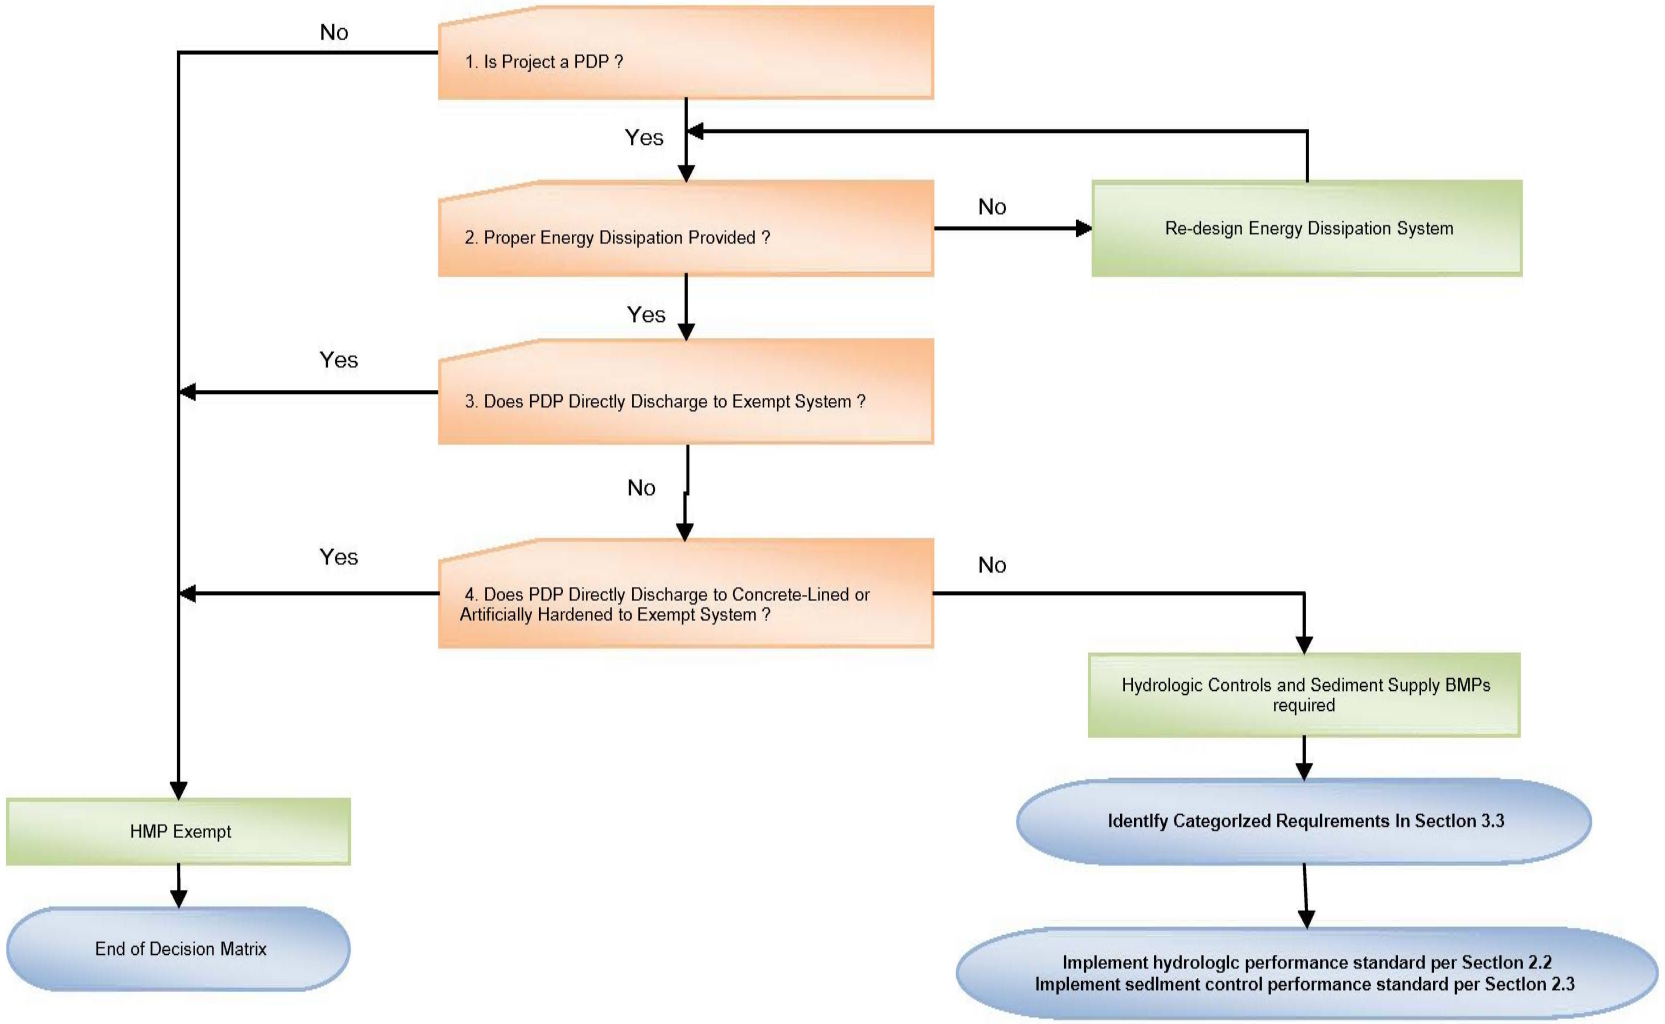
The Copermittees have developed the SMR HMP Monitoring Program, which defines both a Hydromodification monitoring approach and a mechanism for assessing and addressing cumulative impacts from PDPs within a watershed on channel morphology, as required by provisions F.1.h. (1)(m) and F.1.h. (1)(n) of the 2010 SMR MS4 Permit. The mechanism includes an evaluation of changes over time to physical features of receiving channels which are located downstream of urbanized areas. The findings of the initial monitoring efforts will be considered during assessment of priority water quality conditions in the SMR.

3.0 HMP Requirements for Projects

Per 2010 SMR MS4 Permit Provision F.1.h(1)(d), this chapter identifies where in the SMR and under what circumstances do the HMP Performance Standards apply to PDPs. The HMP identifies the coverage areas that are exempted from Hydromodification requirements based on Permit Provisions, the state of the Hydromodification science, the practicality of implementation of Hydrologic Control BMPs, environmental benefits of the implementation of Hydrologic Control BMPs, and approved Hydromodification exemptions for other jurisdictions in California.

Users may refer to the HMP Decision Matrix presented in **Section 3.1** to determine if Hydrologic Control and/or Sediment Supply BMPs are required. When required, the HMP Decision Matrix will direct the User to the adequate sections of this HMP describing the Hydrologic Control and Sediment Supply BMPs to be implemented based on the project type and size.

3.1 HMP Applicability Requirements



3.1.i HMP Decision Matrix

To determine if a proposed project must implement Hydrologic Control BMPs, refer to the HMP Decision Matrix in **Figure 6.**

The HMP Decision Matrix can be used for all projects. PDP categories are based on the size and type. Their associated requirements are defined in **Section 3.3**.

It should be noted that all PDPs are subject to the 2010 SMR MS4 Permit's LID and water quality treatment requirements even if Hydrologic Control BMPs are not required.

Figure 6 - SMR HMP Decision Matrix

- **Figure 6**, Node 1 – Hydrologic Control BMPs are only required if the proposed project is a PDP, as defined per 2010 SMR MS4 Permit Section F.1.d.
- **Figure 6**, Node 2 – Properly designed energy dissipation systems are required for all PDP outfalls to unlined channels. Such systems should be designed in accordance with the District Standard Drawings and the 1982 Los Angeles County Flood Control District Hydraulic Design Manual or approved alternative to ensure downstream channel protection from concentrated outfalls (identified in **Section 3.1.ii)**.
- **Figure 6**, Node 3 – Exemptions may be granted for PDPs discharging runoff directly to an exempt receiving water, such as Vail Lake or Skinner Lake, or to an exempt channel discharging directly into a large river channel (identified in **Table 3**).
- **Figure 6**, Node 4 – For PDPs discharging runoff directly to a concrete-lined or artificially hardened MS4 facility that has the capacity to convey the 10-year ultimate condition discharge that extends to exempt receiving waters detailed in Node 3, exemptions from HMP Performance Standards may be granted. Such concrete-lined or artificially hardened MS4 facilities that have the capacity to convey the 10-year ultimate condition discharge, include storm drain and channel reaches that have been identified as not-susceptible to Hydromodification (see SMR Hydromodification Susceptibility Study in **Appendix C**).
- **Figure** provides an overview of the SMR, and identifies potentially exempt areas per the requirements of the 2010 SMR MS4 Permit and non-exempt areas.
- **Figure 8** and **Figure 9** zoom geographically into the Temecula area and the Temecula Creek area downstream of Vail Lake, respectively.

3.1.ii Requirement for Proper Energy Dissipation System(s)

As identified in the HMP Decision Matrix in **Figure 6**, properly designed energy dissipation systems are required for all PDP outfalls to unlined channels. The provision is consistent with the District's Standard Design Manual and the 1982 Los Angeles County Flood Control District Hydraulic Design Manual or approved alternative to ensure downstream channel protection from concentrated outfalls.

For reference purposes, the 1982 Los Angeles County Flood Control District Hydraulic Design Manual identifies that (page B-12):

"When a storm drain outlets into a natural channel, an outlet structure shall be provided, which prevents erosion and property damage. Velocity of the flow at the outlet should agree as closely as possible with the existing channel velocity. Fencing and a protection barrier shall be provided…

(1) … When the discharge velocity is high, or supercritical, the designer shall, in addition, consider bank protection in the vicinity of the outlet and an energy dissipation structure."

In order to encroach upon a Copermittee MS4 facility and construct an energy dissipation system, an Encroachment Permit must be obtained during the design phase. The User may contact the

District's Operations and Maintenance Division or the Copermittee's Public Works Department, as appropriate, for up-to-date criteria as to location and type of location to be used prior to initiating any design of outlet structure. For a majority of projects seeking encroachment to a MS4 facility, the initial location and type of outlet structures and energy dissipation systems will typically be assessed during the planning phase, specifically during the Environmental Review and Document phase.

Figure 7 - SMR Channel Susceptibility and Exemption Coverage

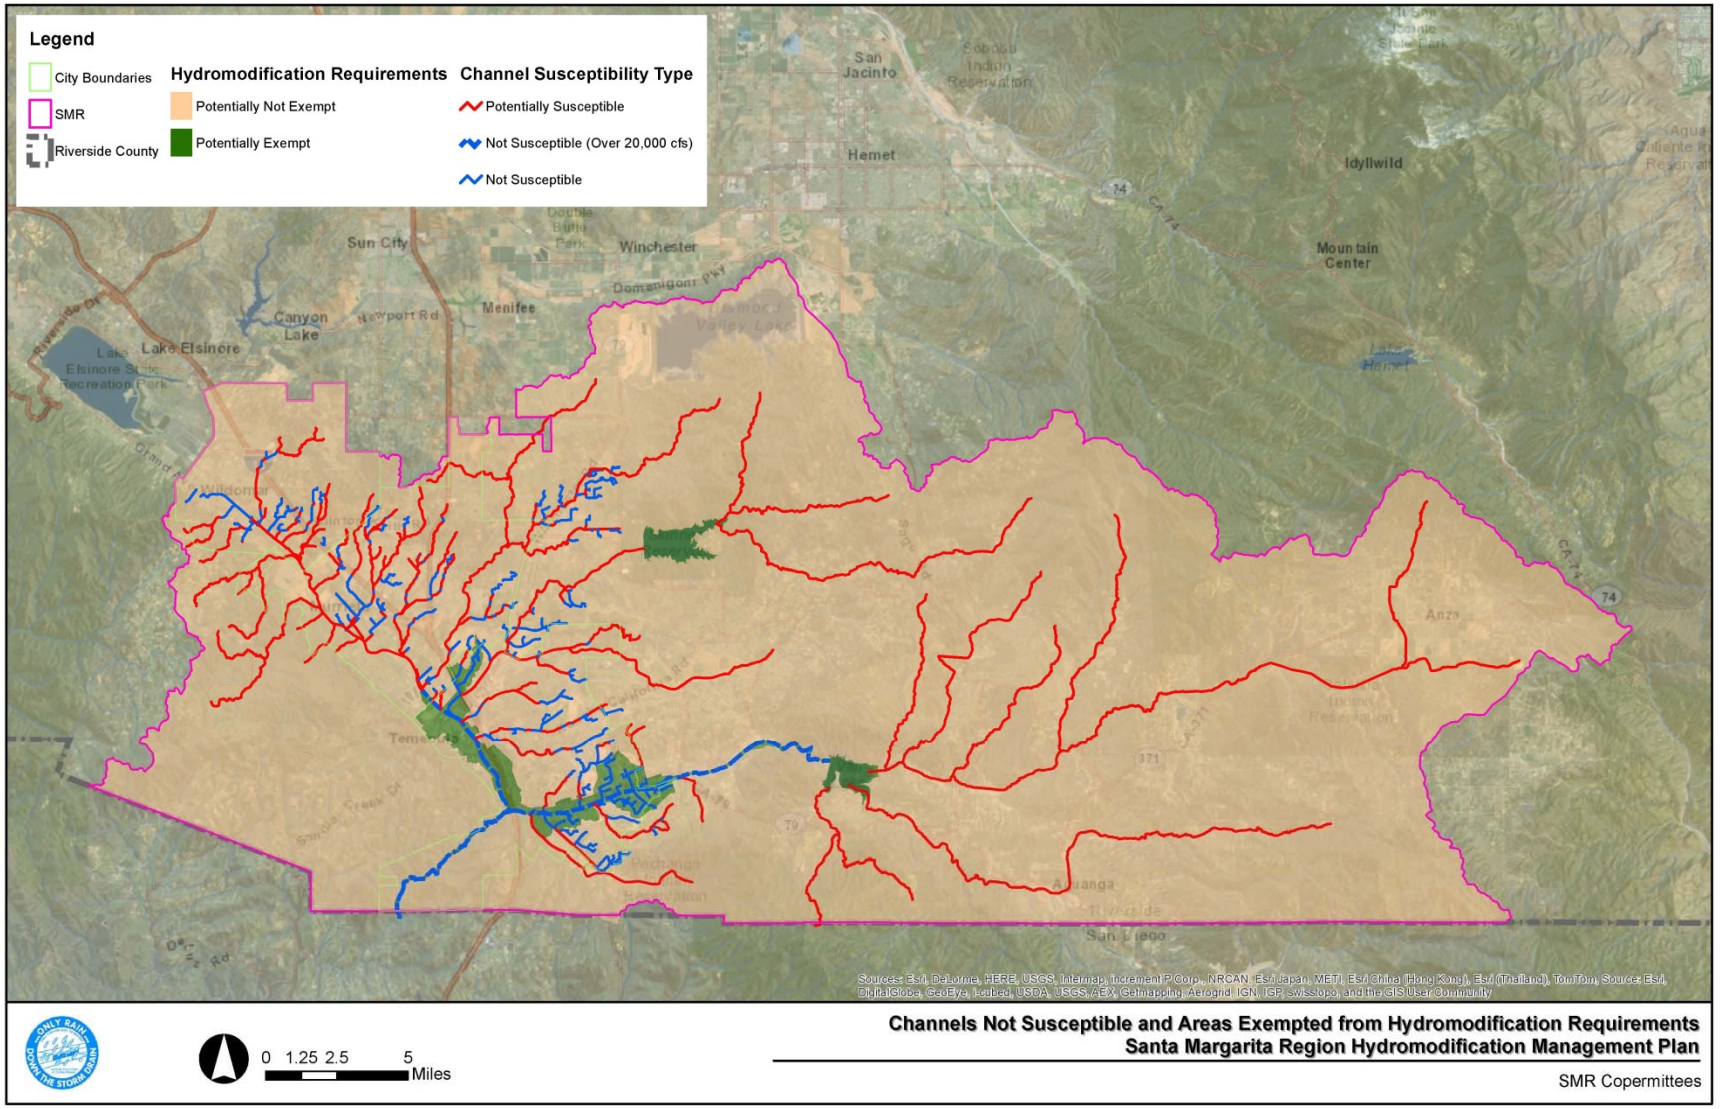


Figure 8 - SMR Channel Susceptibility and Exemption Coverage – Temecula Area

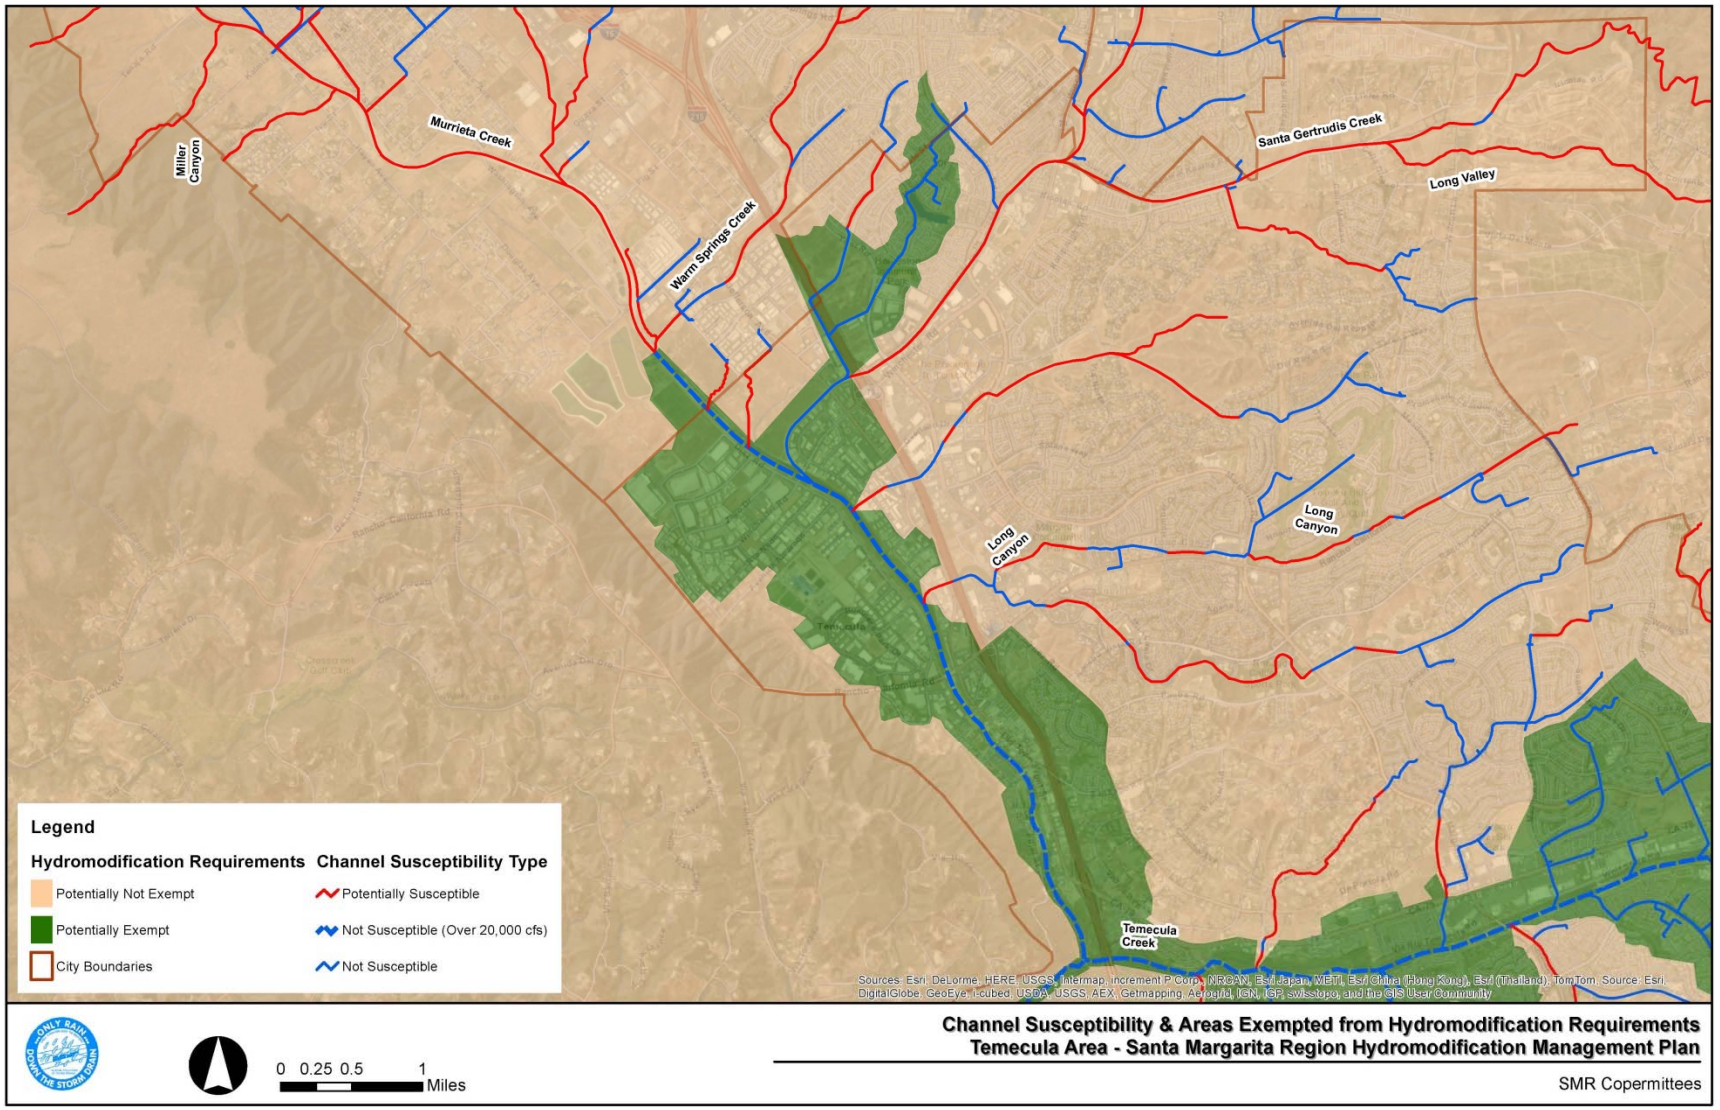

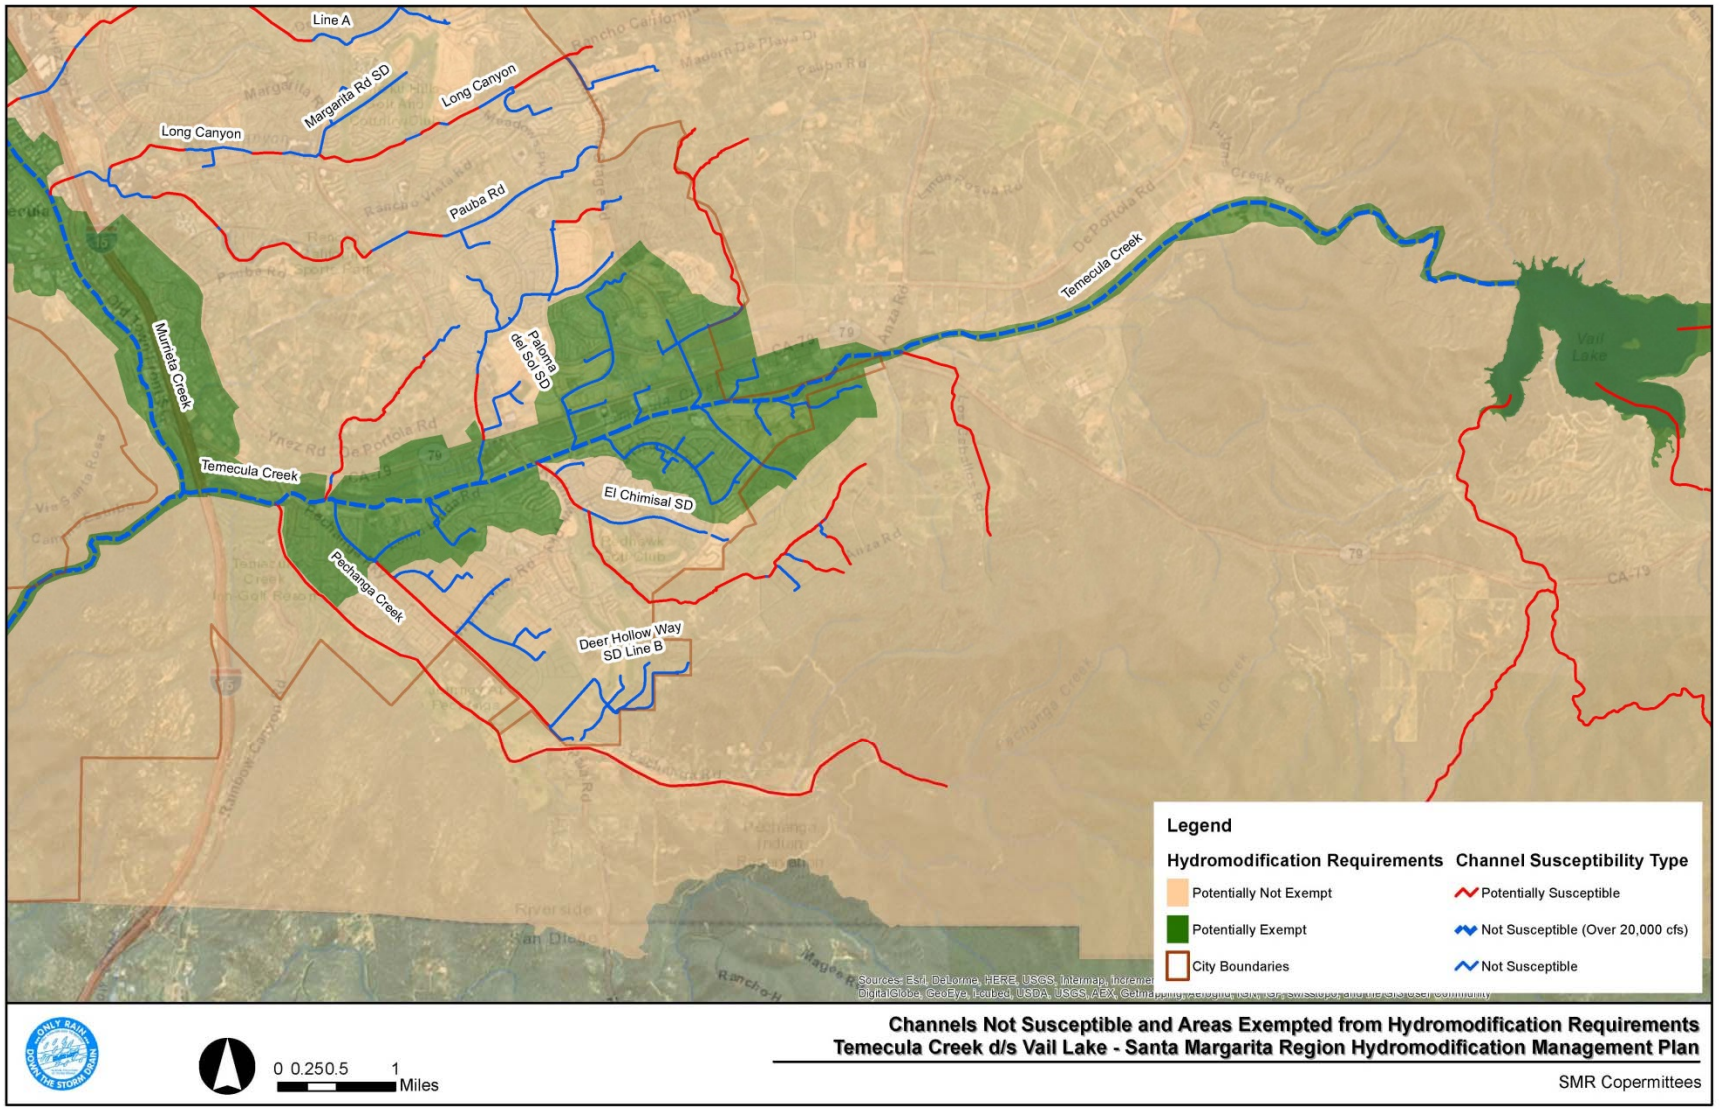

Figure 9 - SMR Channel Susceptibility and Exemption Coverage – Temecula Creek Area

3.2 HMP Exemptions

PDPs may be exempt from HMP Performance Standards based on specific channel or watershed conditions or already approved design guidelines.

3.2.i Concrete-Lined & Artificially Hardened Channel Exempt Areas

The channel exempt areas include those areas that discharge to concrete-lined or artificially hardened channels sections. This includes, as identified in Section F.1.h.(4) of the Permit:

- PDPs that discharge runoff into underground storm drains discharging directly to water storage reservoirs and lakes; or
- PDPs that discharge runoff into MS4 facilities whose bed and bank are concrete lined all the way from the point of discharge to water reservoirs and lakes; or
- PDPs that discharge runoff into other areas identified in the HMP as acceptable to not need to meet the requirements of Section F.1.h by the San Diego Water Board Executive Officer.

Concrete-lined or artificially hardened MS4 facilities that are identified as Engineered, Fully Hardened and Maintained (EFHM) in the SMR Hydromodification Susceptibility Study (see APPENDIX D) are exempt from the HMP Performance Standards. The exemption does not apply to PDPs that discharge to Engineered, Partially Hardened and Maintained (EPHM) and Engineered, Earthen and Maintained (EEM) channels. To confirm the exemption, the succession of existing concrete-lined or artificially hardened MS4 facilities must be continuous from the discharge point to an exempt receiving water, such as a reservoir or a large river. PDPs may evaluate local drainage systems that were not included in the SMR Hydromodification Susceptibility Report for exemption applicability. The User must ensure that the MS4 facilities have been designed to convey the 10-year ultimate condition peak discharge.

The 10-year flow should be calculated based upon the 10-year high confidence synthetic rainfall hydrograph, as detailed in the 1978 RCFCWCD Hydrology Manual. As an alternative, the 10-year ultimate peak discharge may also be determined based on continuous simulation and the results of the SMRHM.

Pursuant to 2010 SMR MS4 Permit Provision F.1.h(1)(a), the SMR was screened to identify and classify susceptible and non-susceptible channels. The screening analysis consisted of verifying the type of material and susceptibility of the GIS-delineated District drainage facilities using as-built plans and aerial photography. For questionable segments, the analysis was complemented by a field visit. Findings are summarized in the Hydromodification Susceptibility Documentation Report and Mapping (see APPENDIX D).

Major MS4 facilities that are exempt from HMP Performance Standards are presented in **Table 3** for reference only. The PDP may use the exemption maps, including Figures 6 through 11 of this

HMP and Map 2: HCOC Applicability Map from the Hydromodification Susceptibility Documentation Report and Mapping: SMR (see APPENDIX D), for planning purposes and must determine if the PDP would discharge runoff into a continuous succession of existing concrete-lined or artificially hardenedMS4 facilities that have the capacity to convey the 10-year ultimate condition discharge all the way to an exempt reservoir or other exempt waterbody. The table contains the name of the channel, as well as the associated downstream and upstream limits. The upstream limit being reported corresponds to the nearest cross street. The resulting map from this effort is presented in **Figure** . The map shows drainage areas that are potentially exempt from HMP Performance Standards.

Table 3 - Channels Exempt from Hydromodification Performance Standards

Channel	Downstream Limit	Upstream Limit
Murrieta Creek	Confluence with Warm Spring Creek	600 feet downstream of Elm Street
Storm Drain RCFC5429	Santa Gertrudis Creek Lateral A,B	Lock Haven Center
Santa Gertrudis Creek Line I	Santa Gertrudis Creek Lateral A,B	End of Line I
Santa Gertrudis Creek Lateral A,B	Murrieta Creek Channel	Confluence with Storm Drain RCFC4057
Wolf Valley Creek Channel	Temecula Creek	Loma Linda Road
Wolf Valley – Loma Linda Road Storm Drain	Wolf Valley Creek Channel	None – all tributaries are exempt
Via Del Coronado Storm Drain	Temecula Creek	None – all tributaries are exempt
Line V / VV of Temecula Creek	Temecula Creek	Upstream of tunneling structure under CA-79
Apis Road Storm Drain	Temecula Creek	None – all tributaries are exempt
Wolf Valley Loop / Margarita Road Storm Drain	Temecula Creek	None – all tributaries are exempt
Mahlon Vail Circle Storm Drain	Temecula Creek	None – all tributaries are exempt
DePortola Road Storm Drain	Temecula Creek	Butterfield Stage Park
Butterfield Stage Road / Macho Road Storm Drain	Temecula Creek	None – all tributaries are exempt
Temecula Creek Road Storm Drain	Temecula Creek	Highway 79
Chaote Street Storm Drain	Temecula Creek	None – all tributaries are exempt
Nighthawk Pass Storm Drain	Temecula Creek	None – all tributaries are exempt
Temecula Creek	Confluence with Santa Margarita River	Outflow of Vail Lake

Table 4 provides a summary of the two exempt reservoirs in the SMR, as identified in the Hydromodification Susceptibility Study. Discharges from PDPs to large reservoirs or lakes can be exempt from HMP Performance Standards since stormwater inflow velocities are naturally managed by the significant tailwater condition in the reservoir. HMP Performance Standard exemptions would only be granted for PDPs discharging runoff directly to the exempt reservoirs or into concrete-lined or artificially hardened MS4 facilities designed convey the 10-year ultimate condition discharging into a lake or reservoir. To qualify for the exemption, the outlet elevation of the MS4 facility must be within (or below) the normal operating water surface elevations of the reservoir and properly designed energy dissipation must be provided.

Table 4 - Reservoirs in the Santa Margarita Region

Reservoir	Watershed
Vail Lake	Temecula Creek

Skinner Lake	Tucalota Creek
Diamond Valley Reservoir	

Figure 10 below displays areas that are potentially exempt for the entire SMR based on the criteria outlined above, where the areas in green are potentially exempt as they discharge to engineered MS4 facilities all the way to exempt receiving waters (large river, water storage reservoirs). **Figure 11** provides the User with an exemption map of higher definition in the Temecula area. **Figure 12** provides the User with an exemption map of higher definition for Temecula Creek downstream of Vail Lake.

Figure 10 - SMR Exemption Area

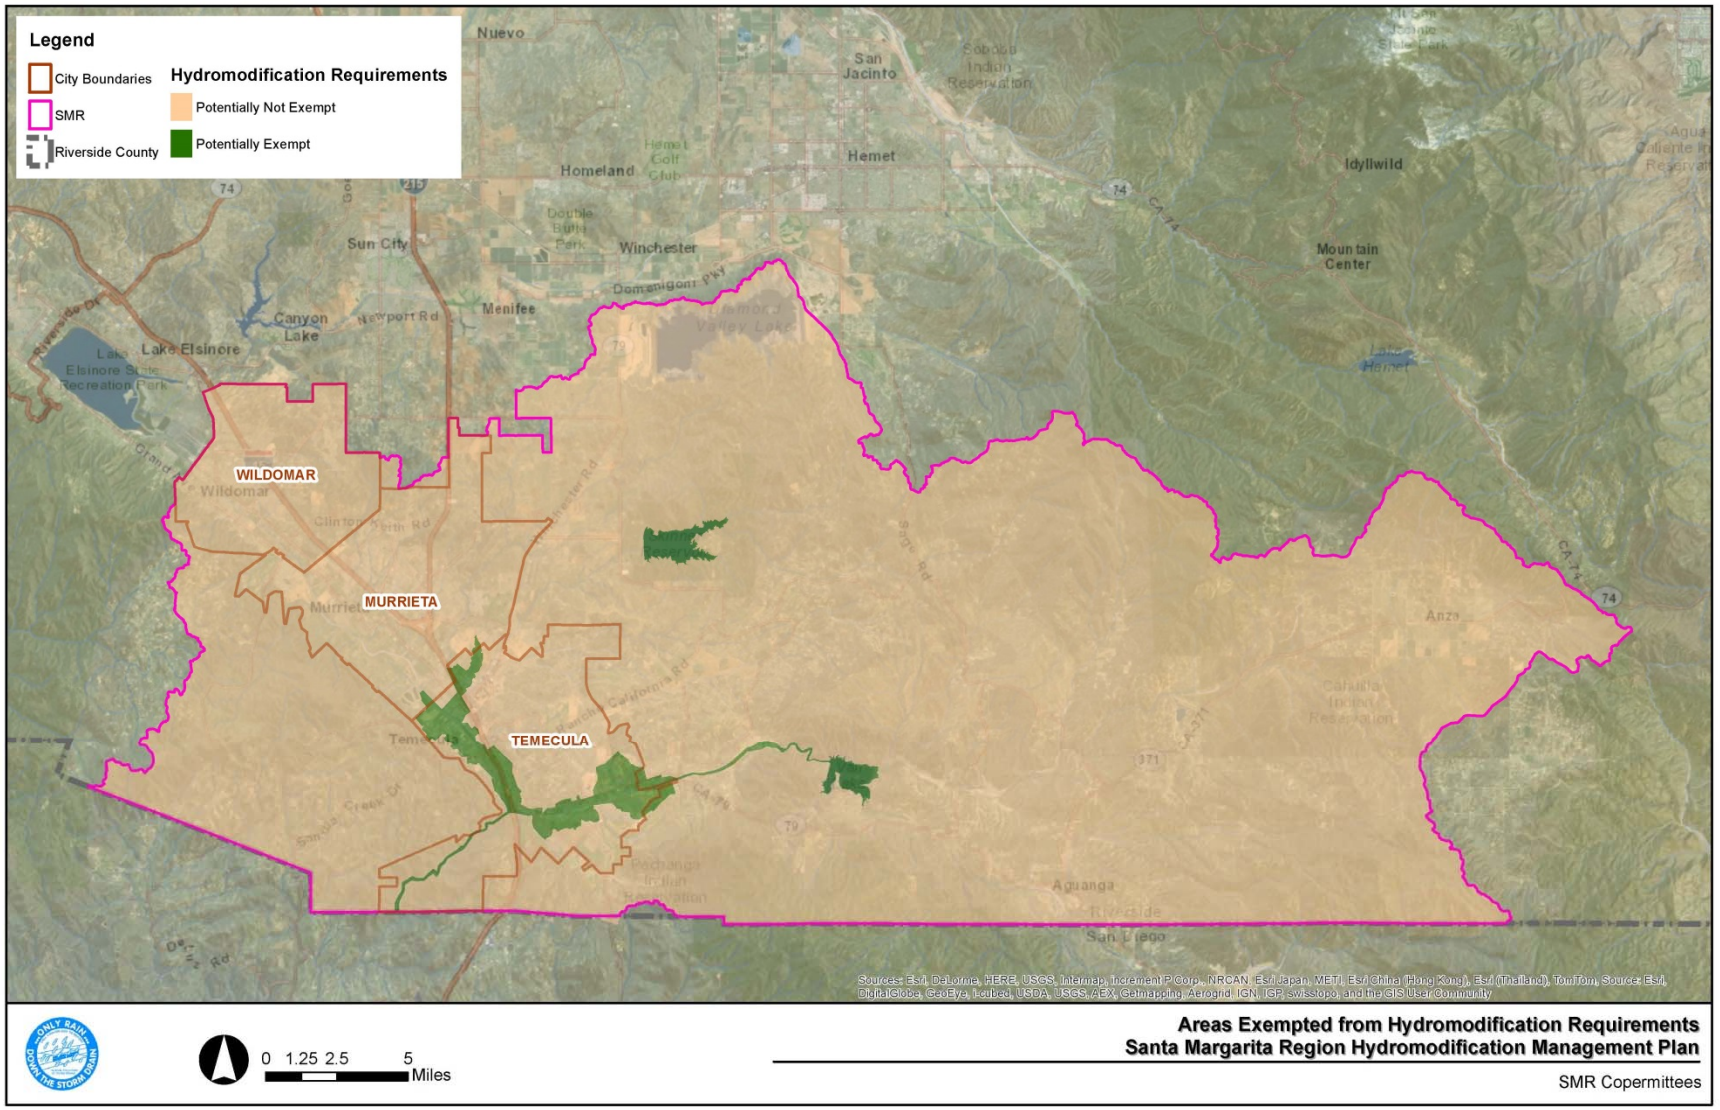

Figure 11 - SMR Exemption Area – Temecula Area

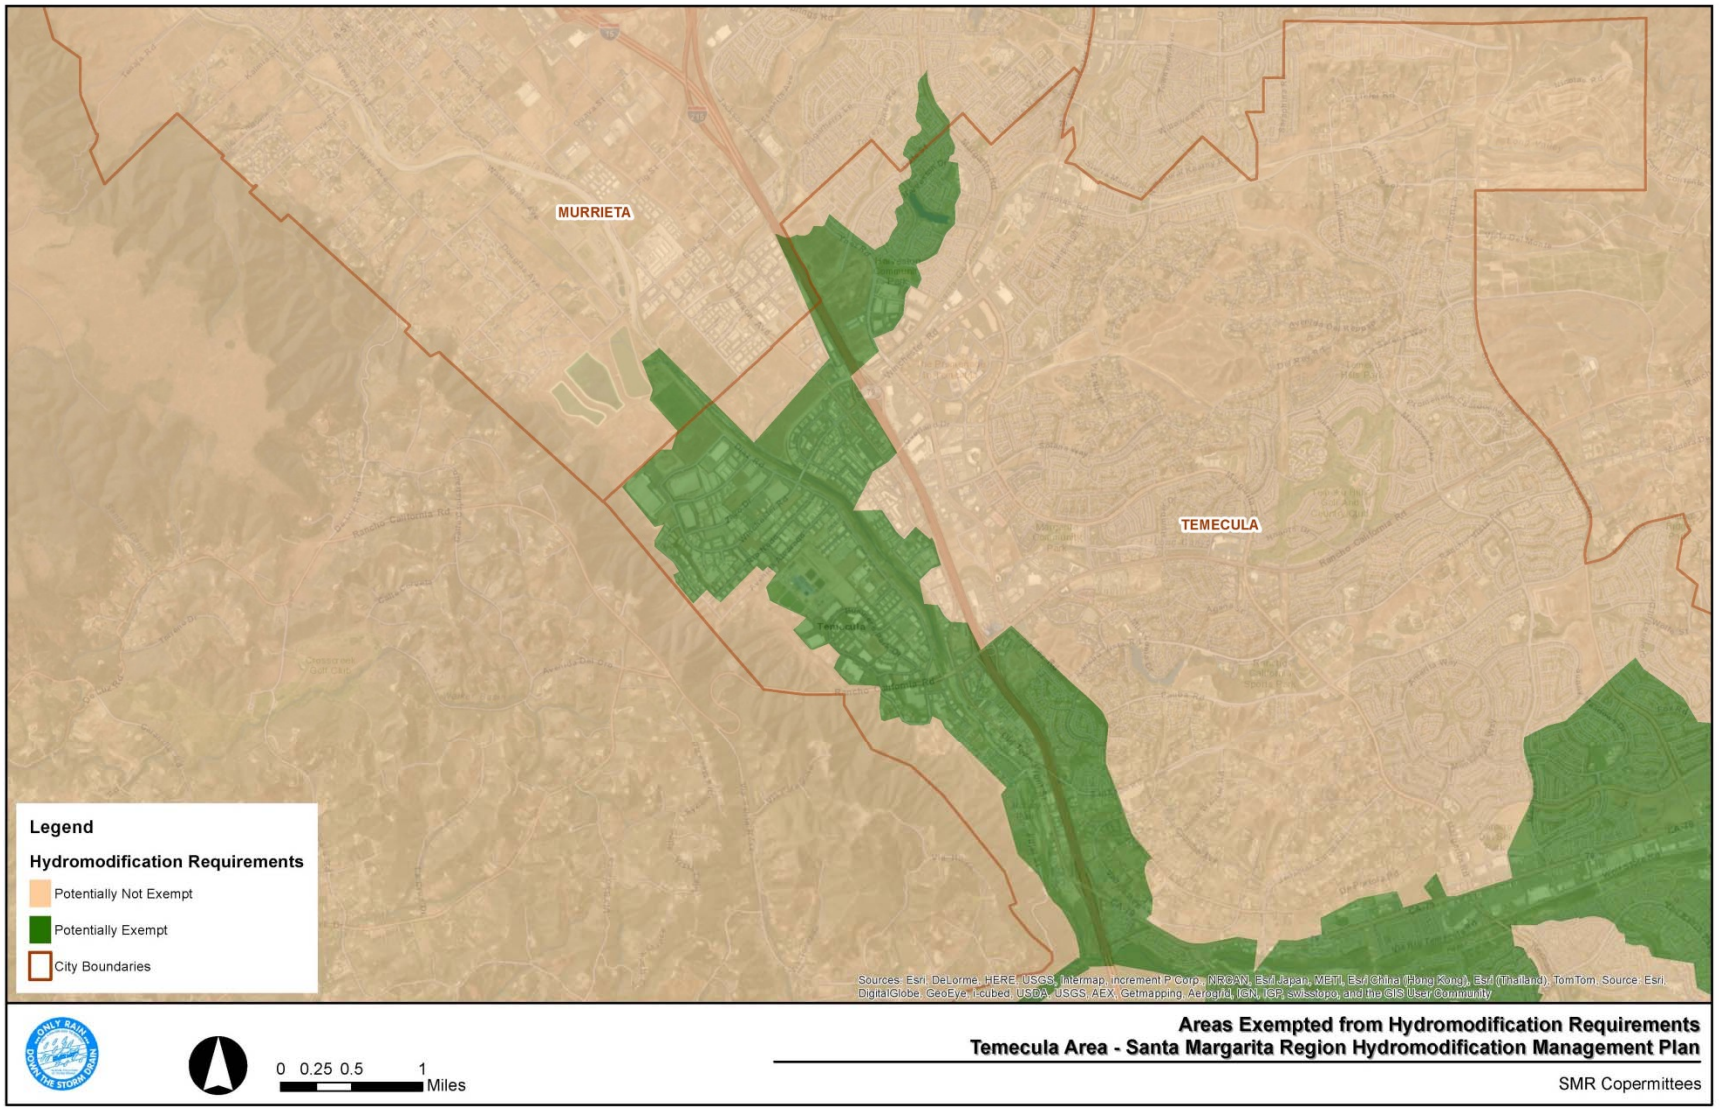

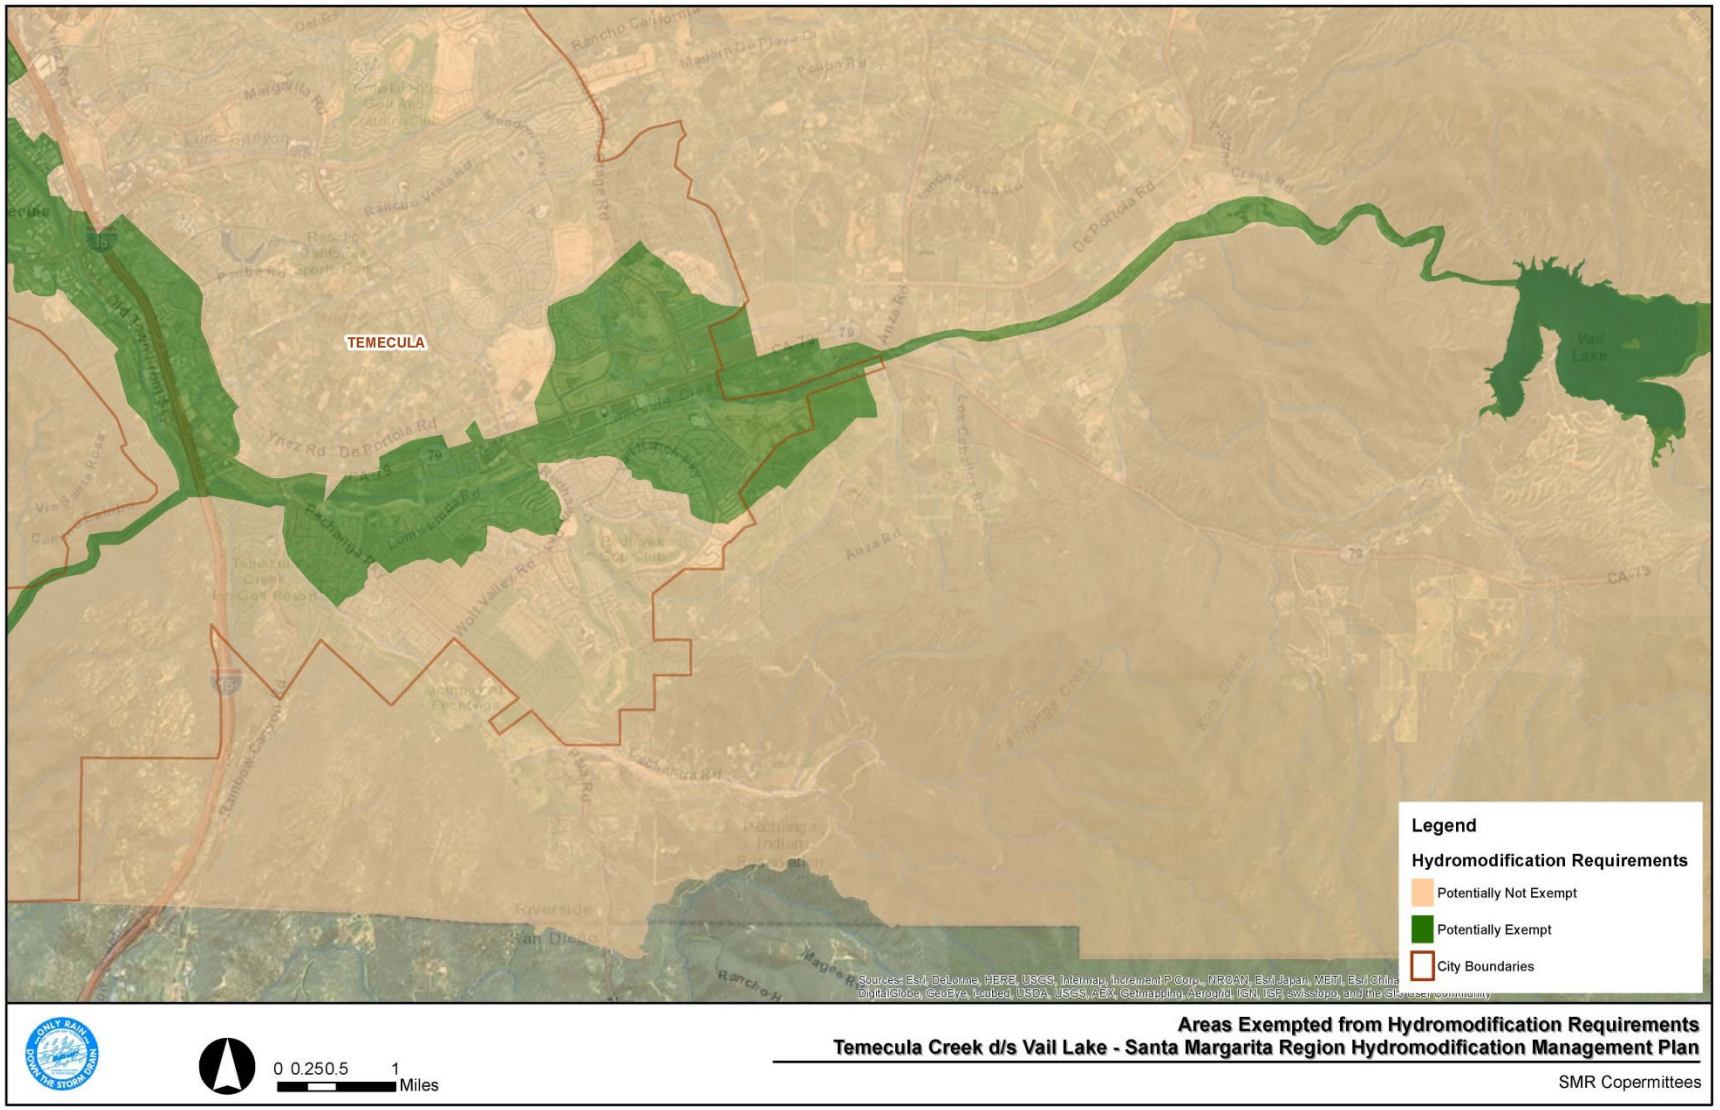

Figure 12 - SMR Exemption Area – Temecula Creek downstream of Vail Lake

3.2.ii Exemption for Large River Reaches

Effects of cumulative watershed impacts are minimal in channel reaches of large depositional rivers. These large rivers typically have very wide floodplain areas when in the natural condition or are stabilized when in the engineered condition, and are of low gradient.

The results of a flow duration curve analysis that was performed for the San Diego River are presented in the San Diego County HMP. This analysis demonstrated that the effects of cumulative watershed impacts are minimal in those reaches for which the contributing drainage area exceeds 100 square miles and with a 100-year design flow in excess of 20,000 cfs. Development and redevelopment projects that discharge either directly or via an engineered and regularly maintained MS4 facility designed to convey the 10-year ultimate condition into such large river channels are hence exempt from the SMR HMP requirements, provided that properly sized energy dissipation is implemented at the outfall location. As identified in the SMR Hydromodification Susceptibility Study (See APPENDIX D), all exempt river reaches, which are presented in **Table 5** have a drainage area larger than 100 square miles and a 100-year design flow higher than 20,000 cfs. **Table 5** also provides the corresponding upstream and downstream limits to define the exempted reach.

Table 5 - Exempt Channel Reaches in the Santa Margarita Region

River	Downstream Limit	Upstream Limit
Murrieta Creek	Confluence with Santa Margarita River	Above Warm Springs Creek
Temecula Creek	Confluence with Santa Margarita River	Outlet of Vail Lake
Santa Margarita River	Pacific Ocean	At Origin

3.3 PDP Requirements

A proposed PDP that is not located in an exemption zone (see **Figure** , **Figure** , or **Figure**) must meet the HMP Performance Standards defined in **Section 2.1**, following the guidelines described in this section. The User may refer to **Figure** , **Figure** , and **Figure** to identify a potential exemption from Hydromodification requirements. To confirm the eligibility to an exemption from Hydromodification requirements, if any, the User must identify in the Preliminary WQMP:

- The list of successive MS4 facilities and Receiving Waters that the project site is tributary to, from the point of discharge of the project site to an exempt Receiving Water. Exempt Receiving Waters are identified in **Section 3.2**.
- For each listed MS4 facility or Receiving Water, if bed and banks are artificially hardened or concrete-lined.

The exemption from Hydromodification requirements will be considered by the Copermittee having jurisdiction over the project site, if all MS4 facilities and Receiving Waters to an exempt Receiving Water, are concrete-lined and/or artificially hardened.

The User may associate the size and type of the PDP to one of the following Categories and meet all the HMP Performance Standards outlined for that category:

- Category 1 – New Development Projects exceeding one acre or Redevelopment Projects over one acre
- Category 2 – Small-sized projects less than one acre yet defined as a PDP and Copermittee roadway projects

Proposed PDPs face different levels of spatial, environmental, financial, technical, and permitting constraints based on their size and type. As such, the 2010 SMR MS4 Permit was translated into HMP Performance Standards that are specific and adapted to each Category. The definition of each Category was principally derived from the elements of the 2010 SMR MS4 Permit, as well as from a review of the other HMPs (Santa Clara, Alameda, Sacramento, San Diego, and South Orange County). Most individual single-family residential projects will be exempt from the HMP Performance Standards.

The following subsections describe the HMP Performance Standards specific to each Category.

3.3.i Category 1 – PDPs over One Acre

Category 1 PDPs will be subject to a number of spatial, environmental, financial, technical, and permitting constraints.

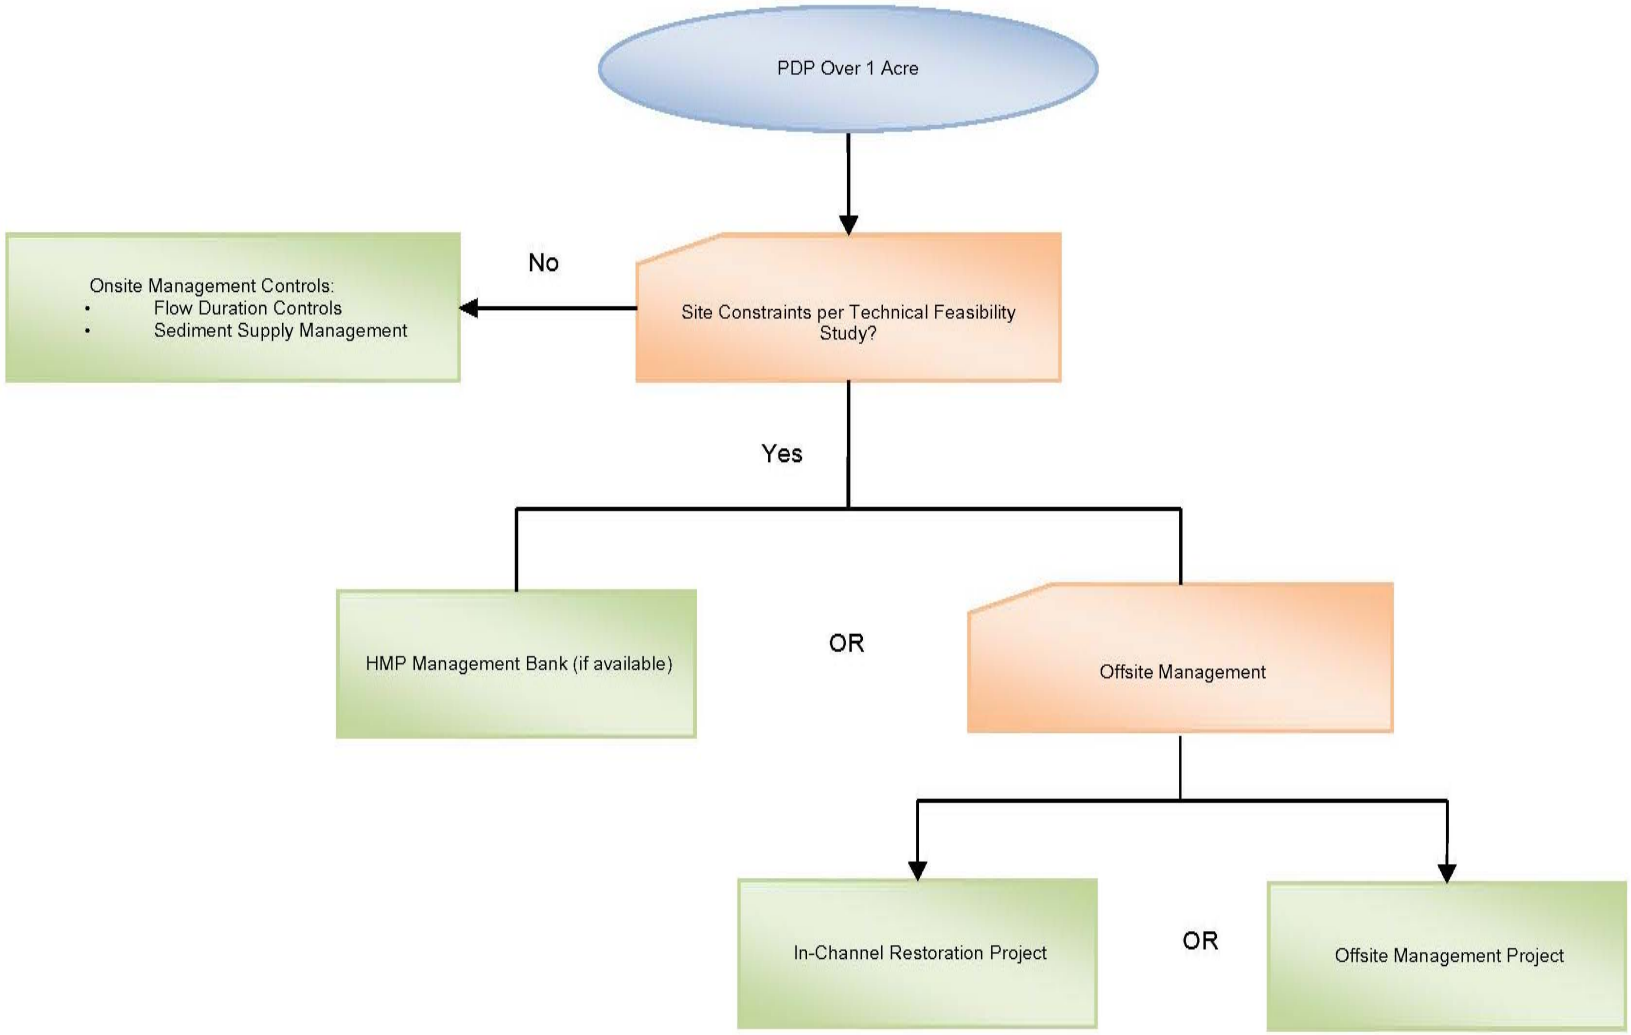
Hydrologic Control and Sediment Supply BMPs to ensure compliance with the HMP Performance Standards are described in **Section 2.1**. Using this approach, management of both flow and duration is achieved through onsite Hydrologic Control BMPs or implementation of hydrologic controls through a regional or sub-regional BMP that accepts discharges from the project, but is located outside of the project boundaries, and sediment loss is addressed through Sediment Supply BMPs.

If allowed by the Copermittee with jurisdiction over the project site, a PDP that is greater than 100 acres or a PDP in a common development plan that exceeds 100 acres may implement Comprehensive Regional BMPs. Comprehensive Regional BMPs must address the incremental impacts of the PDP on the receiving channels from a regional perspective. The User must delineate the subwatersheds that include entirely the project site to demonstrate compliance with the water quality, hydrologic, and fluvial geomorphologic objectives from a regional perspective. The following objectives must be addressed in implementing Comprehensive Regional BMPs:

- Water Quality Objectives, LID site principles, LID BMPs to capture or biotreat the Design Capture Volume (DCV), and HMP Performance Standards in consistency with the requirements set forth in the SMR WQMP;
- Copermittee and regional hydrologic objectives to manage increases in runoff peak discharges and increases in runoff volumes for the 10-year and 100-year frequency storm events, in consistency with the drainage requirements set forth by the Copermittee having jurisdiction over the project;

- Fluvial geomorphologic objectives to manage the adverse impacts of the PDPs over the existing aggradation/degradation of the receiving channel, and the existing stability and erosion of the receiving channels for the 10-year and 100-year frequency storm events, in consistency with the drainage requirements set forth by the Copermittee having jurisdiction over the project.

A PDP may benefit from the implementation of Comprehensive Regional BMPs instead of separate Hydrologic Control BMPs to address NPDES and Local Drainage requirements through the reduction of the overall footprint of Hydrologic Control BMPs, the simplification of the required MS4 facilities, the streamlined maintenance of facilities for optimal operability, and the potential to create multi-use facilities.



Comprehensive Regional BMPs may be onsite or offsite Hydrologic Control BMPs implemented to address regional water quality, hydrologic, and fluvial geomorphologic objectives consistent with the framework of a regional technical study. Comprehensive Regional BMPs will typically be larger detention facilities with a water quality component that manages the DCV, a Hydromodification component including the design of additional storage and adequate outlet structure to manage the range of geomorphically significant flows (10% of Q2 to Q10, or consistent with the guidelines provided in APPENDIX I), and a drainage mitigation component including the design of additional storage and adequate outlet structure to manage increases in runoff peak discharges, runoff volumes, receiving channel aggradation/degradation, channel erosion & channel stability.

The User must develop a regional technical study to demonstrate that the HMP Performance Standards are met for the sub-watersheds that include entirely the project site, through the implementation of Comprehensive Regional BMPs. The regional technical study must be submitted along with the Project-Specific WQMP. The User may consider the following approaches:

- For the Hydrologic Performance Standard, the User may follow Step 1 in **Section 2.2.iv**. If a HMP Management Bank is available, the PDP can pursue this option. The PDP can also pursue the in-channel restoration or rehabilitation option (Option 1 – Step 2b) identified in **Section 2.2.iv**.
- For the Sediment Control Performance Standard, the User may perform the three-step approach as described in **Section 2.3.i**. The alternative compliance will consist of modifying the hydrologic regime of onsite runoff to compensate for sediment loss, while meeting the established Hydrologic Performance Standard.

The Alternative Compliance Options to meet both the Hydrologic Control and Sediment Control Performance Standards are intrinsically related. A flow chart indicating which HMP Performance Standards should be pursued and implemented for a Category 1 project is shown in **Figure 13**

Figure 13 - Hydromodification Performance Standards for PDPs Over One Acre

3.3.ii Category 2 –PDPs less than one acre & Copermittee Roadway Projects

Category 2 PDPs are those projects disturbing an area less than one acre but defined as a PDP. Category 2 PDPs may include the following projects, as characterized by 2010 SMR MS4 Permit Provision F.1.d.(1) and Provision F.1.d.(2):

- New Development Projects that are smaller than one acre that create 10,000 square feet or more of impervious surfaces (collectively over the entire project site) including commercial, industrial, residential, mixed-use, and public projects. This category includes New Development Projects on public or private land which fall under the planning and building authority of the Copermittees.
- Projects to construct automotive repair shops, defined as a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.
- Projects to construct restaurants defined as a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption (SIC code 5812), where the land area for development is greater than 5,000 square feet. Restaurant projects where land development is less than 5,000 square feet must meet all WQMP requirements except for Structural Treatment BMP and numeric sizing criteria requirement F.1.d.(6) and Hydromodification requirement F.1.h.
- All hillside development projects greater than 5,000 square feet but less than one acre. This category is defined as any development which creates 5,000 square feet of impervious surface which is located in an area with known erosive soil conditions, where the development will grade on any natural slope that is 25% or greater.
- All development projects less than one acre that are located within or directly adjacent to or discharging directly to an ESA (where discharges from the development or redevelopment will enter receiving waters within the ESA), which either creates 2,500 square feet of impervious surface on a proposed project site or increases the area of imperviousness of a proposed project site to 10% or more of its naturally occurring condition. "Directly adjacent" means situated within 200 feet of the ESA. "Discharging directly to" means outflow from a drainage channel that is composed entirely of flows from the subject development or redevelopment site, and not commingled with flows from adjacent lands.
- Impervious parking lots 5,000 square feet or more and potentially exposed to runoff. Only parking lots that are less than one acre are included into Tier 3. Parking lots are defined as a land area or facility for the temporary parking or storage of motor vehicles used personally, for business, or for commerce.
- Retail Gasoline Outlets (RGOs) - This category includes RGOs that meet the following criteria: (a) 5,000 square feet or more or (b) a projected Average Daily Traffic of 100 or more vehicles per day. RGO projects that are less than one acre are included into Tier 3.

- Those Redevelopment projects less than one acre that create, add, or replace at least 5,000 square feet of impervious surfaces on an already developed site and the existing development and/or the redevelopment project falls under the project categories or locations listed in 2010 SMR MS4 Permit Provision F.1.d.(2). Where redevelopment results in an increase of less than 50% of the impervious surfaces of a previously existing development, and the existing development was not subject to WQMP requirements, the numeric sizing criteria discussed in 2010 SMR MS4 Permit Provision F.1.d.(6) applies only to the addition or replacement, and not to the entire development. Where redevelopment results in an increase of more than 50% of the impervious surfaces of a previously existing development, the numeric sizing criteria applies to the entire development.

In addition, Copermittee Roadway Projects are included in Category 2. Copermittee Roadway Projects are linear New Development or Redevelopment projects to be completed within a limited right-of-way. Category 2 includes also the following roadway projects, as defined per Permit Provisions F.1.d.(1) and F.1.d.(2):

- Streets, roads, highways, and freeways. This category includes any paved surface that is 5,000 square feet or greater used for the transportation of automobiles, trucks, motorcycles, and other vehicles. To the extent that the Copermittees develop revised standard roadway design and post-construction BMP guidance that comply with the provisions of Section F.1 of the Order, then public works projects that implement the revised standard roadway sections do not have to develop a WQMP.
- Roadway Redevelopment Projects that create, add, or replace at least 5,000 square feet of impervious surfaces. Where a roadway Redevelopment Project results in an increase of less than 50% of the impervious surface within the limits of the project, and the existing development was not subject to WQMP requirements, the numeric sizing criteria discussed in Permit Provision F.1.d.(6) applies only to the addition or replacement, and not to the entire development. Where the roadway Redevelopment Project results in an increase of more than 50% of the impervious surface within the limits of the project, the numeric sizing criteria applies to the entire project.

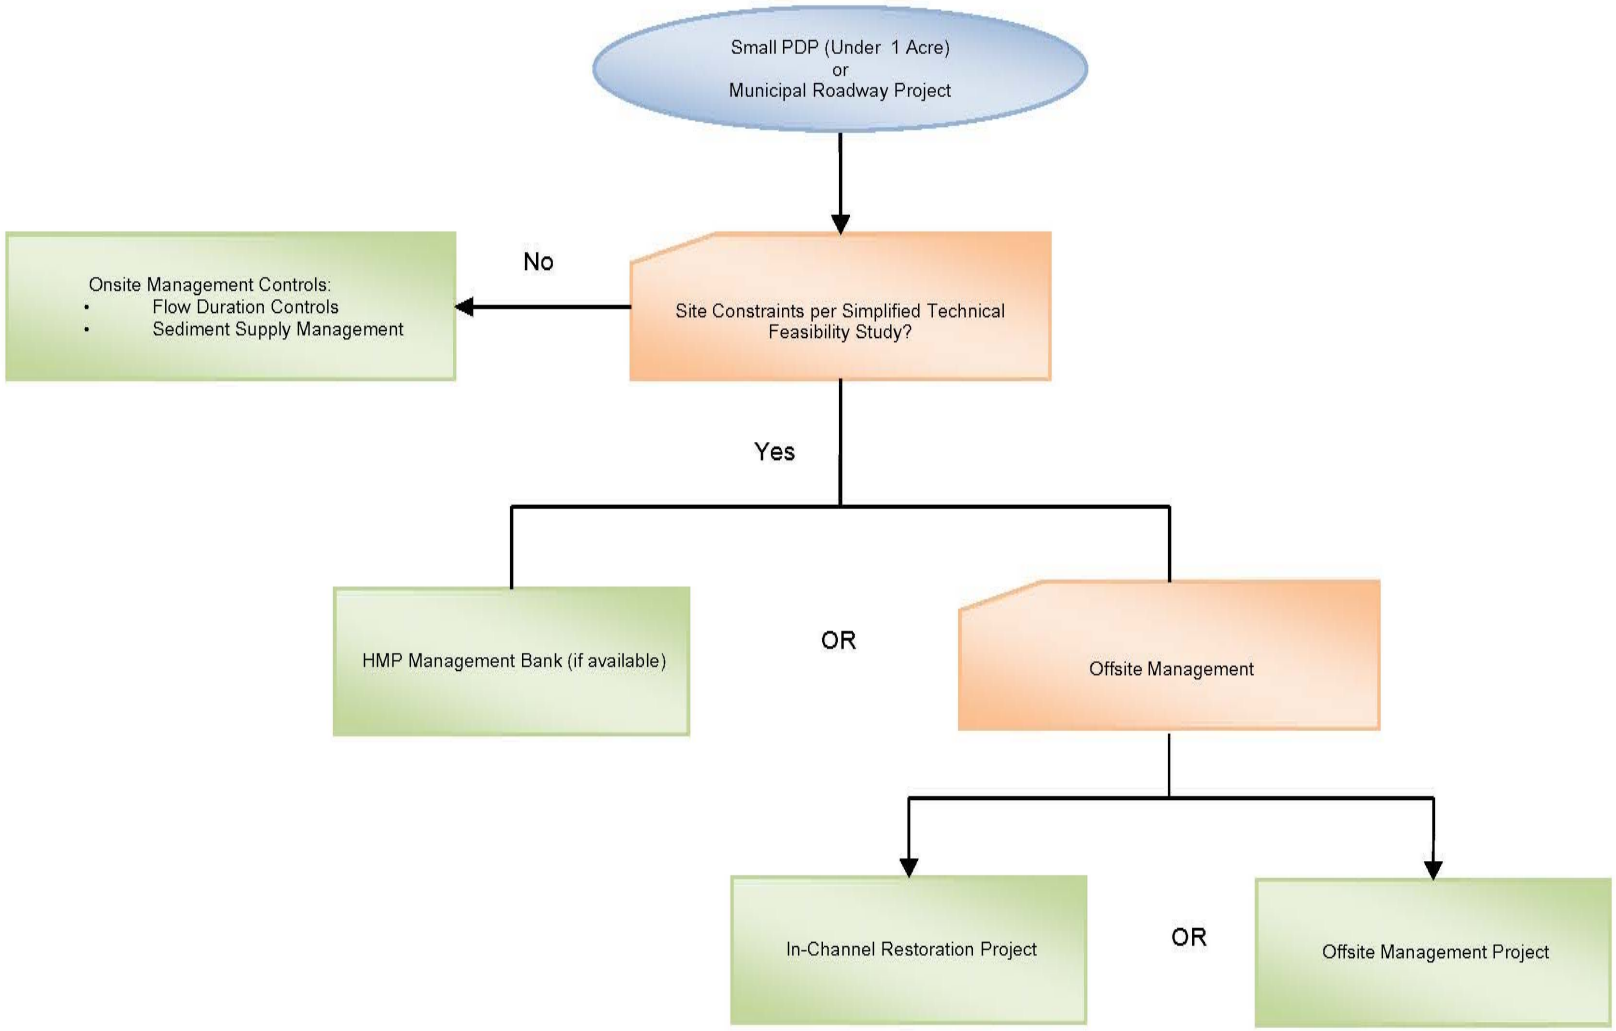
Attachment C of the 2010 SMR MS4 Permit identifies that:

> "Redevelopment does not include trenching and resurfacing associated with utility work; resurfacing existing roadways; new sidewalk construction, pedestrian ramps, or bike lane on existing roads; and routine replacement of damaged pavement, such as pothole repair."

The majority of Category 2 projects are completed within a limited amount of space, making it unlikely the User will be able to implement onsite Hydrologic Control and Sediment Supply BMPs. The following approaches are available:

- Implementing Hydrologic Control BMPs either within the project boundaries or through a regional or sub-regional BMP that accepts discharges from the project, but is located outside of the project boundaries and Sediment Supply BMPs to ensure compliance with

the HMP Performance Standards identified in **Section 2.1**. Using this approach, management of both flow and duration is achieved through Hydrologic Control BMPs.



- If onsite Hydrologic Control BMPs are not technically feasible due to site constraints, a simplified technical feasibility study must be developed to explain why the HMP Performance Standards cannot be met onsite. The simplified technical feasibility study must include:

    - the soil conditions of the PDP site;
    - a demonstration of the lack of available space for onsite Hydrologic Control BMPs;
    - an explanation of prohibitive costs to implement onsite Hydrologic Control BMPs; and
    - a written opinion from a California Registered Geotechnical Engineer, who will identify the infeasibility due to geotechnical concerns.

- Once the simplified technical feasibility study is accepted by the Copermittee with jurisdiction over the project site, the User may pursue payment into the HMP Management Bank, if one exists and is available to the PDP. If not, the User must pursue either an offsite Hydrologic Control BMP project or an in-channel restoration or rehabilitation project detailed in Option 1 – Step 2b in **Section 2.2.iv**. The offsite management project or in-channel restoration will meet the hydrologic performance standard.

A flow chart indicating which HMP performance standard should be considered for a Category 2 PDP is shown in **Figure 14**.

Figure 14 - Hydromodification Performance Standards for Small Size PDPs

4.0 HMP and Model WQMP Integration

Within the SMR WQMP, the HMP Performance Standards are incorporated into Section 3.6 – Meet Hydromodification Requirements. The section also identifies HMP Performance Standards for Category 1 and 2 PDPs, as well as the methodology and steps that Users must follow to achieve compliance with these Performance Standards. The alternatives for compliance with HMP Performance Standards – Off-Site Management and 3.6.3.b) – HMP Management Bank, and Section 3.6.4 – Meet the Sediment Supply Performance Standard, respectively will also be integrated into Sections 3.6.3.a) of the WQMP.

Guidance regarding the Hydrologic Control BMP technical feasibility study has also been integrated with the LID feasibility analysis as part of Section D of the SMR WQMP Template. Section D of the SMR WQMP Template addresses evaluation of onsite conditions that may require implementation of offsite Hydrologic Control BMPs. The Copermittees will use the SMR WQMP, WQMP Template, and LID BMP Design Handbook to incorporate the HMP Performance Standards into their development approval processes via their WQMPs and ordinances.

APPENDIX A - User Quick Start Sheet

The quick start summary lists the following steps that a User should follow for their PDP to meet the HMP Performance Standards:

1. The first step consists of verifying if the project is exempt from HMP Performance Standards. Exemption occurs:

    - If the project is not classified as a PDP per the 2010 SMR MS4 Permit Provision F.1.d.;
    - If the proposed project discharges runoff directly to an exempt Receiving Water such as an exempt river reach, or an exempt reservoir. Or, if the proposed project discharges to an engineered MS4 facility with the capacity to convey the 10-year ultimate condition that extends to the an exempt river reach or reservoir (See **Section 3.2.i**);
    - If the project discharges to a large river per the definition provided in **Section 3.2.iii;** or
    - If the project discharges to stable Receiving Waters per the results of a channel stability analysis (See **Section** Error! Reference source not found.).

2. If not exempt from HMP Performance Standards, the User should identify the Performance Standards that apply to the PDP Category of the proposed project. For specific Category Performance Standards, the User may refer to the HMP Decision Matrix referenced in **Section 3.1**and requirements listed in **Section 3.3**. These direct the User to implement, when required, Hydrologic Control and Sediment Supply BMPs following the approach listed in **Section 2.0**:

    a. Hydrologic Control BMPs

Figure 13 summarizes the options that a User may pursue to achieve Hydrologic Control Performance Standards. Prioritization of Hydrologic Control BMPs, as well as the applicability of each type of Hydrologic Control BMPs, is defined in **Figure 13**. Onsite Hydrologic Control BMPs are to be designed based on the SMRHM. Alternatively, the User may develop their own numerical criteria but should support the findings with continuous simulation models. Technical infeasibility of a type of Hydrologic Control BMP should be documented. Specifics are provided in **Section 2.2**.

Figure 13 - SMR HMP Options for Hydrologic Control BMPs

Type of Hydrologic Control BMP	Onsite	Regional	Offsite (management or in-channel restoration)	Management Bank (if available)	Green Street Project or equivalent
Large (>100 ac)	Yes	Yes	n/a	n/a	n/a
Medium (1 ac ≤A≤100 ac)	Yes - #1	n/a	Yes - #2a	Yes - #2b	n/a
Small (<1 ac)	Yes - #1	n/a	Yes - #2a	Yes - #2b	n/a
Public roadway	n/a	n/a	Yes	n/a	Yes

b. Sediment Supply BMPs

The User may follow a three-step process to ensure maintenance of the pre-project sediment supply to the channel:

1. Determine whether the site is a significant source of Bed Sediment Load to the receiving channel.
2. Avoid areas of significant Bed Sediment Load supply in the site design.
3. Replace areas of significant Bed Sediment Load supply that are eliminated through urban development.

If the three-step process is deemed infeasible, an alternative compliance option allows the User to model the site conditions and the receiving channel and provide additional management in site runoff to compensate for the reduction (or addition) of Bed Sediment Load. Specifics are detailed in **Section 2.3.ii**.

1. The User should integrate Hydrologic Control and Sediment Supply BMPs into the project site design, and define the design specifics in the preliminary project-specific WQMP that should be submitted to the Copermittee with jurisdiction over the project site. The Copermittee may approve the proposed design upon identification of compliance with the HMP Performance Standards.

APPENDIX B - Copermittee HMP Development Process

The District was the lead in the Copermittee development of the HMP. The Copermittees participated financially and through participation in HMP workshops. The workshops were scheduled over the course of the project at times corresponded with key decision points in the development of the HMP. Participants in the HMP workshops provided valuable input on the development of the HMP.

The Copermittees will continue to meet to discuss and resolve issues that may arise during HMP implementation. Participants in the HMP development process will also assist in refining and reinforcing methodologies, criteria, and standards established in the HMP.

The group of participants in the SMR HMP development process has met four times since October 2012. **Table 6** shows meeting dates, locations, and agenda items. In addition to the formal meetings, the Copermittees coordinated via email to review and discuss technical documents, deliberate on specific HMP related topics, and concur on issues.

Table 6 - SMR HMP Copermittee Meetings

Date	Location	Agenda
October 29, 2012	District, Riverside	SMR HMP Outline and Approach Presentation of the San Diego Hydrology Model Tool
December 2012	City Hall, Murrieta	Presentation and discussion of the first Draft SMR HMP Presentation and discussion of the HMP Evaluation Program Schematic
March 2013	City Hall, Temecula	Presentation and discussion of the second Draft SMR HMP Presentation and discussion of the Draft HMP Evaluation Program
April 2013	District, Riverside	SMRHM Training Workshop
May 2013	City Hall, Temecula	Presentation and discussion of the Final SMR HMP Presentation of the Final HMP Evaluation Program
June 2014	District, Riverside	Compliance document training

A Draft SMR HMP was submitted to the SDRWQCB in June 2013 and a proposed final HMP that addressed the SDRWQCBs comments was submitted on March 10, 2014. The final HMP was submitted on July 11, 2014 to address the additional SDRWQCBs comments received on April 8, 2014 and incorporate the Final SMR HMP requirements into the SMR WQMP. In addition, the Copermittees used the revised SMR WQMP to incorporate the HMP requirements into their development approval processes through their WQMPs and municipal ordinances.

As required by Permit Provision F.1.h(5)(a), the draft document was posted on the District's website in January 2013 (http://rcflood.org/NPDES/SantaMargaritaWS.aspx) for public review and comment. The Final Draft SMR HMP was also posted on the District's website for a second round of public review and comment.

APPENDIX C - State of the Hydromodification Science: A Literature Review

Pursuant to 2010 SMR MS4 Permit Provision F.1.h(1)(g), this appendix provides the results of a literature review conducted as a basis for the development of the HMP.

Hydromodification in the context of this HMP refers to changes in the magnitude and frequency of channel flows due to urbanization and the resulting impacts on the receiving channels in terms of erosion, sedimentation, and degradation of in-channel habitat. The processes involved in aggradation and degradation are complex, but may be affected by an alteration of the hydrologic regime of a watershed due to increases in impervious surfaces, more efficient MS4 facilities, and a change in historic sediment supply sources, among other factors. The study of Hydromodification is an evolving field, and regulations to manage the impacts of Hydromodification must be grounded in the latest science available.

HMPs seek ways to manage Hydromodificaton that may result from urban development by establishing requirements for controlling runoff from New Development and Redevelopment projects. In order to establish appropriate requirements for New Development and Redevelopment, it is important to understand 1) how land use changes alter stormwater runoff; and 2) how these changes can impact receiving channels. These and other issues central to HMPs adopted in California have been addressed in numerous journal articles, books, and reports. This literature review builds upon previous literature reviews developed for the South Orange County HMP and the San Diego County HMP, including recent studies or information relevant to Southern California.

C.1. Hydromodification Management Concepts

There are many different approaches to managing Hydromodification impacts from urban development, and most HMPs provide multiple options for achieving and documenting compliance with National Pollutant Discharge Elimination System (NPDES) MS4 permit requirements. In general, hydrograph management approaches focus on managing runoff from a developed area to not increase instability in a channel, and in-channel solutions focus on managing the receiving channel to accept an altered flow regime without becoming unstable. This section briefly summarizes various approaches for HMP compliance.

C.1.1. Stability of Alluvial Channels

Southern California channels typically combine steep slopes and erodible materials with a predominance of sand and gravel substrates, which may be assimilated to alluvial channels (SCCWRP, 2011). An exchange of material between the inflowing sediment load and the bed and banks of the channel is established, thus creating a constant adjustment of the channel's width, depth, slope, and planform in response to changes in water or sediment discharge (NEH, 2007). A channel planform is defined as the horizontal alignment of a channel as observed from a point

perpendicular to the Earth's surface (USDA, 2007). Natural alluvial channels constantly form their geometry by moving boundary material to react to changes in precipitation and the rate of tectonic uplift. Lane's interrelationship (1955) conceptualizes this balance between hydrologic and geomorphic processes for alluvial channels:

$$Q_s \times D_{50} \propto Q_w \times S$$

Where:

Q_s = Sediment discharge

D_{50} = Median sediment size

Q_w = Flow

S = Channel Slope

As seen by Lane's interrelationship, if any of the four variables is altered, one or more of the remaining variables must change.

Due to natural and/or man-made conditions, such as construction of Vail Lake and Skinner Reservoir, a majority of channels within the SMR are dynamically adjusting to a new geomorphic equilibrium corresponding to the altered hydrology and sediment transport regimes. The tributary areas to both Vail Lake and Skinner Reservoir consist primarily of mountainous highlands, with narrow, deeply incised drainages whose rate of incision is naturally dependent on precipitation and the rate of tectonic uplift. In addition, the construction of Vail Dam and Skinner Reservoir and historical urbanization within the SMR have progressively altered the hydrology and sediment transport regimes in the downstream channels. Approximately two-thirds of the Upper Santa Margarita River Watershed is controlled by these dams, which conserve virtually all of the runoff for municipal, industrial and agricultural use. Recent observations of the downstream channels show that the latter are still geomorphically adjusting to the altered hydrology and sediment transport regimes. Downstream of the constructed dams, the reduction in frequency and magnitude of discharges into Temecula Creek and Tulacota Creek has resulted in a significant reduction of the cumulative work performed in those downstream channels (See Section C.2.1.), which may result into increased aggradation of Temecula Creek, Tulacota Creek, and their respective downstream reaches. In essence, the SMR is a dynamic system that is still converging towards a geomorphic equilibrium.

In addition to Vail Lake and Skinner Reservoir, the Permittees have constructed a significant storm drain infrastructure to control storm water discharges from urbanized areas and provide an adequate level of protection against flooding hazards in urbanized communities. Currently, two-thirds of the SMR are controlled by controlled-release points, or flood control basins that effectively reduce the magnitude and frequency of incoming storm water discharges. In areas tributary to those controlled-release points, increases in runoff discharge, magnitude, and frequency associated with future urbanization are managed to ensure the long-term stability of downstream channels, thus resulting in aggradation in those downstream channels.

For those channels that are not influenced by dams and controlled-release points, urban development in the upstream reaches will usually result in increased runoff, causing an

incremental reduction in channel slope (S) through downcutting or increased channel meander to the existing dynamic adjustment due to the construction of Vail Dam and Skinner Reservoir. Urban development may also result in incremental change in sediment discharge (Qs). Bed sediment load is derived from the channel bed and banks. If channels are altered by urban development in such a way as to reduce or increase sediment discharge, instability may occur.

Only a portion of the total sediment load in a channel is important for channel stability. Total channel sediment load may be classified by size or transport mechanism. The wash load commonly refers to the portion of the total sediment load that remains continuously in suspension (based on particle size). The wash load has a nominal impact on channel stability. Bed sediment load refers to the material that moves along the channel bed via Saltation, and is continuously in contact or exchange with the channel bed. Bed sediment load is the critical portion of total sediment discharge for channel stability.

C.1.2.Hydrologic Management Measures

Facilities that detain or infiltrate runoff to manage development impacts are the focus of most HMP implementation guidance. They work by either reducing the volume of runoff (infiltration facilities) or holding water and releasing it below the critical flow (Qc) (detention facilities). These facilities, also referred to as Hydrologic Control BMPs, can range from regional detention basins designed solely for flow control, to bioretention facilities that serve a number of functions. A number of Hydrologic Control BMPs, including swales, bioretention, flow-through planters, and extended detention basins have been developed to manage stormwater quality, and several resources describe the design of stormwater quality BMPs (CASQA 2003; Richman et al. 2004). In many cases, these facilities can be designed to also meet Hydrologic Performance Standards.

Many HMPs also provide guidance for applying LID approaches to site design and land use planning to preserve the hydrologic cycle of a watershed and manage Hydromodification impacts. These plans typically include decentralized stormwater management systems and protection of natural drainage features, such as wetlands and channel corridors. Runoff is typically directed toward infiltration-based stormwater BMPs that slow and treat runoff. Hydrologic Control BMPs differ from those used to meet Water Quality Objectives in that they focus more on generating a flow duration curve that matches or reduces the undeveloped flow duration curve than on removing potential Pollutants, although these two functions can be combined into one facility. Various methods exist for sizing Hydrologic Control BMPs.

- **Hydrograph Matching** uses an outflow hydrograph for a particular site that matches closely with the pre-project hydrograph for a design storm. This method is most traditionally used to design flood-detention facilities to manage for a particular storm recurrence interval (e.g., the 100-year storm). Although hydrograph matching can be employed for multiple storm recurrence intervals, this method generally does not take into account the smaller, more frequent storms that are identified by the actual state of the science as performing a majority of the erosive work on channels and is therefore not widely accepted for HMP compliance nor recommended for use as a part of this HMP.

- **Volume Control** matches the pre-project and post-construction runoff volume for a project site. Any increase in runoff volume is either infiltrated onsite, or discharged to

another location where channels will not be impacted. The magnitude of peak flows and Time of Concentration is not controlled, so while this method ensures there is no increase in total volume of runoff, it can result in higher erosive forces during storms.

- **Flow Duration Control** matches or reduces both the duration and magnitude of a specified range of storms. The entire hydrologic record is taken into account, and pre-project and post-construction runoff magnitudes and volumes are matched as closely as possible. Excess runoff is either infiltrated onsite or discharged below Qcp (Geomorphically critical flow – 10% of the 2-year flow).

The Santa Clara Valley Urban Runoff Pollution Prevention Program (SCVUPPP) HMP reviewed each of these methods and concluded that a Flow Duration Control approach was the most effective in controlling erosive flows. Two examples were evaluated using this approach, one on the Thompson Creek subwatershed in Santa Clara Valley and one on the Gobernadora Creek watershed in Orange County. The evaluation approach used continuous simulation modeling to generate flow duration curves, and then designed a test Hydrologic Control BMP to match pre-project durations and flows.

In addition to the SCVURPP HMP, the flow duration control approach has been applied by the Alameda Countywide Clean Water Program, San Mateo County Water Pollution Prevention Plan, the Fairfield-Suisun Urban Runoff Management Program, Contra Costa Clean Water Program, San Diego County, and South Orange County. Among these agencies, different approaches have emerged on how to demonstrate that proposed Hydrologic Control BMPs meet flow duration control guidelines. Both methods employ continuous simulation to match or reduce flow durations, but differences exist in how continuous simulation is used (site-specific simulation vs. unit area simulation). Differences also exist in the focus of the two approaches (regional detention facilities vs. onsite LID facilities). Both approaches were evaluated by the different RWQCBs and deemed valid (Butcher 2007).

Other existing HMPs have defined an approach to design and implement hydrologic control BMPs, including Counties of the Bay Area and Contra Costa County.

BAHM Approach

The Bay Area Hydrology Model (BAHM) is a continuous simulation rainfall runoff hydrology model developed for ACCWP, SMCWPPP, and SCVURPP. It was developed from the Western Washington Hydrology Model, which focuses primarily on meeting Hydromodification Management Performance Standards using stormwater detention ponds alone or combined with LID facilities (Butcher 2007). The Western Washington Hydrology Model is based on the Hydrologic Simulation Program – FORTRAN (HSPF) modeling platform, developed by the USEPA, and uses HSPF parameters in modeling watersheds.

Users who want to size a Hydrologic Control BMP select the location of their project site from a map of the Bay Area and BAHM correlates the project location to the nearest rainfall gauge and applies an adjustment factor to the hourly rainfall for the nearest gauge, to produce a weighted hourly rainfall at the project site. The User then enters parameters for the proposed project site describing soil types, slope, and land uses. BAHM then runs the continuous rainfall-runoff

simulation for both the pre-project and the post-construction conditions of the project site. Output is provided in the form of flow duration curves that compare the magnitude and timing of storms between the pre-project and the post-construction modeling runs.

If an increase in flow durations is predicted, the User can select and size Hydrologic Control BMPs from a list of modeling elements. An automatic sizing subroutine is available for sizing detention basins and outlet orifices that matches the flow duration curves between the pre-project scenario and a post-construction management scenario. Manual sizing is necessary for other Hydrologic Control BMPs included in the program, such as storage vaults, bioretention areas, and infiltration trenches. The program is designed so that, once a Hydrologic Control BMP is selected and sized, the modeling run can be transferred to the Copermittee with jurisdiction over the project site for approval. The Copermittee model reviewer can launch the program and verify modeling parameters and sizing techniques.

A HMP tool was also developed to support Users with the San Diego County HMP. The San Diego Hydrology Model (SDHM) derives from the BAHM, and integrates parameters that are specific to San Diego County. Similarly, the South Orange Hydrology Model (SOHM) was developed for the purposes of the South Orange County NPDES Permit.

A similar approach will be used for the SMR HMP. The Western Washington Continuous Simulation Hydrology Model (WWHM) has been modified to include local rainfall and loss rate information, in addition to preferred local BMP selection to provide Users a user-friendly tool to develop a Hydromodification management strategy. The SMRHM allows the user to match or reduce the flow duration curve for the selected range of flows using locally preferred BMPs.

Contra Costa Clean Water Program (CCCWP) Approach

The CCCWP developed a protocol for selecting and sizing Hydrologic Control BMPs, which are referred to as Integrated Management Practices (IMPs) in their guidebook. Instead of a User running a site-specific continuous simulation to size Hydrologic Control BMPs, the CCCWP provides sizing factors for designing site level IMPs. Sizing factors are based on the soil type of the project site and are adjusted for Mean Annual Precipitation. Sizing factors are provided for bioretention facilities, flow-through planters, dry wells and a combination cistern and bioretention facility.

Sizing factors were developed through continuous simulation HSPF modeling runs for a variety of development scenarios. Flow durations were developed for a range of soil types, vegetation and land use types, and rainfall patterns for development areas in Contra Costa County. Then, based on a unit area (one acre) of impervious surface, flow durations were modeled using several IMP designs. These IMPs were then sized to achieve flow control for the range of storms required, (from 10% of the 2-year storm up to the 10-year storm). These sizing factors were then transferred to a spreadsheet form for use by Users.

The primary difference between the CCCWP approach and the BAHM approach is the level of modeling required. The CCCWP approach is simplified for the User in that both Hydromodification and water quality management is incorporated into the IMP sizing factors. The BAHM allows for more flexibility in that regional BMPs may be used to meet

Hydromodification Performance Standards, and if desired, water quality, in addition to site level approaches. The 2010 SMR MS4 Permit allows for offsite management of Hydromodification, if the onsite infeasibility of Hydrologic Control BMPs has been demonstrated. Therefore, an approach that uses continuous simulation to assess regional or neighborhood level BMP implementation is preferred for this HMP.

C.1.3. Sediment Management Measures

Urban development can reduce the mass of Bed Sediment transported through the elimination of alluvial channel sections. This occurs in site development when first-order and particularly larger channels are lined or placed into underground conduits. First-order channels are identified as the unbranched channels that drain from headwater areas and develop in the uppermost topographic depressions, where two or more contour crenulations (notches or indentations) align and point upslope (NEH, 2007). First-order channels may, in fact, be field ditches, gullies, or ephemeral gullies (NEH, 2007).

There are two general approaches for managing the Bed Sediment Load relative to urbanization and channel stability. The first approach attempts to correct for the change in Bed Sediment Load material load by increasing or decreasing the discharge rate as appropriate to generally maintain the balance between hydrologic and geomorphic processes as conceptualized in Lane's interrelationship. While theoretically a sound approach, this option requires a significant amount of detailed information that is difficult to obtain and requires good calibration of sediment models.

Sediment transport models are non-linear and relatively sensitive to the rate of sediment supply and particle size distribution. This HMP does not recommend any specific sediment transport equation or model as the selection of such a model should be based on channel and watershed specific information, and the amount and quality of available data. Examples of sediment transport equations the designer may consider include: Duboys Formula, Meyer-Peter Formula, Einstein Bed Load Function, Modified Einstein Procedure, Colby's Method, Engelund and Hansen Method, Ackers and White Method. There are several models that use these transport formulas to predict long-term sediment transport. General guidance for site-specific analysis is provided in APPENDIX H

The second approach to maintaining sediment supply is physically based, relying on a field assessment of site locations that may supply Bed Sediment Load to the receiving channel, and protecting those sources during the site planning and development process. With this approach, the User will only provide engineered solutions for flow management. Protection of site Bed Sediment Load sources is the preferred approach since it is physically based and potentially less prone to error. Guidelines for field assessment of Bed Sediment Load sources are provided with the sediment control management approach, which is described in **Section 2.3**.

C.1.4. In-Channel Stabilization Solutions

In-Channel solutions focus on managing the channel corridor to provide stability, modifying the channel to accept an altered flow regime. In cases where development is proposed in a watershed with an impacted channel it may be beneficial to focus on rehabilitating the channel to match the new independent variables of channel cross section, sediment discharge, flow discharge and channel slope rather than retrofitting the watershed or only controlling a percentage of the runoff with onsite controls. This type of approach can restore channel functions, beneficial uses, and values at a much more rapid pace, especially in locations that cannot physically be returned to their natural state due to changes in channel alignment and restrictions on the channel cross section due to adjacent development. In addition, in some cases where a master planned watershed development plan is being implemented it may be more feasible to design a new channel to be stable under the proposed watershed land use rather than to construct distributed onsite facilities.

In-channel stabilization and restoration solutions are available as alternative compliance as a part of the SMR HMP. In-channel restoration projects are available if onsite Hydrologic Control BMPs are not feasible and it has been determined that the receiving water that the project discharges to has impacts due to Hydromodification. Tiered benefits (benthic communities, morphology) of such in-channel restoration projects must offset the hydrologic and sediment changes induced by the associated PDP(s).

A number of methods exist for managing channels to accept altered flow regimes and higher shear forces. These have been covered in detail in a number of sources available to watershed groups and public agencies. A few helpful sources include Riley 1998, Watson and Annable 2003, and FISRWG 1998.

C.1.5. Channel Susceptibility – Domain of Analysis

Southern California Coastal Water Research Project (SCCWRP) has developed a series of screening tools that evaluate the susceptibility of a channel to Hydromodification impacts (SCCWRP, 2010). These screening tools allow a User to rate the susceptibility of the evaluated channel to erosion for a variety of geomorphic scenarios including alluvial fans, broad valley bottoms, incised headwaters, etc.

The development of HMPs in most Southern California counties is correlated to the ultimate findings of SCCWRP studies on Hydromodification (SCCWRP, 2008 through 2011). It is generally acknowledged that SCCWRPs formulation of regional standards for Hydromodification management may serve as a baseline for development of HMP Performance Standards for specific regions in Southern California.

When evaluating the channel susceptibility though the SCCWRP screening tools, a domain of analysis is defined. This domain of analysis corresponds to the reach lengths upstream and downstream from a project from which Hydromodification assessment is required. The domain of analysis determination includes an assessment of the incremental flow accumulations downstream of the site, identification of grade control points in the downstream channel, and quantification of downstream tributary influences. The SMR program elected not to perform the

extensive susceptibility mapping required to correlate channel reaches with variable low flow discharge thresholds, since the return on investment for this type of analysis appears to be very low.

The effects of Hydromodification may propagate for significant distances downstream (and sometimes upstream) from a point of impact such as a MS4 outfall. Accordingly, the domain of analysis serves as a representative buffer domain across which the susceptibility of a channel should be evaluated. This representative domain spans multiple channel types/settings, and is defined as follows in this HMP (SCCWRP, 2010):

Proceed downstream until reaching the closest of the following:

- at least one reach downstream of the first grade-control point (but preferably the second downstream grade-control location)
- tidal backwater/lentic waterbody
- equal order tributary (Strahler 1952)
- a two-fold increase in drainage area

OR demonstrate sufficient flow attenuation through existing hydrologic modeling.

Proceed upstream to extend the domain for a distance equal to 20 channel widths or to grade control in good condition – whichever comes first. Within that reach, identify hard points that could check headward migration, evidence that head cutting is active or could propagate unchecked upstream

Within the analysis domain there may be several reaches that should be assessed independently based on either length or change in physical characteristics. In more urban settings, segments may be logically divided by road crossings (Chin and Gregory, 2005), which may offer grade control, cause discontinuities in the conveyance of water or sediment, etc.

The domain of analysis is discussed here since it may be relevant for use in site-specific analysis as discussed in APPENDIX H . It is not used in this HMP as a discriminator for HMP applicability to a specific project.

C.2. Flow Duration Control Approach

C.2.1. Effects of Urban Development and Critical Flow

The effects of urban developments on channel response have been the focus of many studies (see Paul and Meyer, 2001 for a review), and the widely accepted consensus is that increases in impervious surfaces associated with urbanizing land uses can cause channel degradation. Urban development generally leads to a change in the amount and timing of runoff in a watershed, which may increase erosive forces on channel bank and bed material and can cause large-scale channel enlargement, general scour, channel bank failure, loss of aquatic habitat, and degradation of water quality.

Channel erosion is a complex process subject to a variety of influences. Channel erosion is non-linear (Philips 2003), meaning the response of channels is not directly proportional to changes in land use and flow regimes. Small changes or temporary disturbances in a watershed may lead to unrecoverable channel instability (Kirkby 1995). These disturbances may give rise to feedback systems whereby small instabilities can be propagated into larger and larger instabilities (Thomas 2001).

A number of studies have sought to correlate the amount of urban development in a watershed and channel instability (Bledsoe 2001; Booth 1990, 1991; Both and Jackson 1997; MacRae 1992; 1993; 1996; Coleman et al. 2005). Evidence from these studies suggests that below a certain threshold of watershed imperviousness, channels maintain stability. This threshold or imperviousness transition zone appears to be around seven to 10% watershed urbanization for perennial channels (Schueler 1998 and Booth 1997), but may begin at a lower level for intermittent channels such as those found in Southern California. Studies done in Santa Fe, New Mexico (Leopold and Dunne 1978) suggest that changes occur at 4% impervious area of the watershed.

Initial studies by Coleman et al. (2005) suggest that a response in the channel may begin to occur at two to 3% watershed imperviousness for intermittent channels in Southern California. It is important to understand that use of impermeable cover alone is a poor predictor of channel erosion due to differences in stormwater detention and infiltration within regions.

In highly urbanized watersheds returning a channel to a natural condition is infeasible due to existing development in the watershed. In these scenarios the focus should be on in-channel restoration to restore the beneficial uses of the Receiving Water.

Though it is well established that watershed urbanization causes channel degradation, a detailed understanding of how development alters runoff and how this altered runoff in turn causes erosion is still being developed.

The ability to transport sediment is proportional to the amount of flow in the channel: as flow increases, the amount of sediment moved within a channel also increases. The ability of a channel to transport sediment is termed stream power, which integrated over time is work. Leopold (1964) introduced the concept of effective work, whereby the flow-frequency relationship of a channel is multiplied by sediment transport rate. This gives a mass-frequency relationship for erosion rates in a channel. Flows on the lower end of the relationship (e.g., two-year flows) may transport less material, but occur more frequently than higher flows, thereby having a greater overall effect on the work within the channel. Conversely, higher magnitude events, while transporting more material, occur infrequently causing less effective work. Leopold found that the maximum point on the effective work curve occurred around the 1-to 2-year frequency range. This maximum point is commonly referred to as the dominant discharge. It corresponds roughly to a bankfull event (a flow that fills the active portion of the channel up to a well-defined break in the bank slope).
The constructions of Vail Lake, Skinner Reservoir, and Diamond Valley Reservoir have effectively created man-made sumps capturing the majority of incoming storm water flows from Temecula Creek, Wilson Creek, Kolb Creek, and Tucalota Creek. At these reservoirs, stormwater may only overtop the spillway(s) and be discharged into the downstream channels during higher magnitude events (10-year and higher magnitude events). Since the completion of the dams, the

reduction in frequency and magnitude of discharges into Temecula Creek and Tulacota Creek has resulted in a significant reduction of the cumulative work performed in those downstream channels.

Urban development tends to have the greatest relative impact on flows that are frequent and small, and which tend to generate less-than-bankfull flows. Change is greatest in these events because prior to urban development, infiltration would have absorbed much or all of the potential runoff, but following urban development, a high percent of the rainfall runs off. Thus, events that might have generated little or no flow in a non-urbanized watershed can contribute flow in urban settings. These smaller less-than-bankfull events have been found to cause a significant proportion of the work in urban channels (MacRae 1993) due to their high frequency, and can lead to channel instability. Less frequent, larger magnitude flows (e.g., flows greater than Q10) are less strongly affected by urban development because during such infrequent storm events, the ground rapidly becomes saturated, and acts (for purposes of runoff generation) in a similar manner as impervious surfaces.

Due to the increase in impervious surfaces and fewer opportunities for infiltration of stormwater, urban development creates a higher runoff rate and more runoff volume than an un-urbanized watershed. Opportunities for infiltration of excess stormwater exist in urbanized areas, but many times are infeasible due to cost, technical barriers or land use constraints. Therefore, some of the excess stormwater must be discharged to a receiving channel. In order to achieve a comparable Ep to a pre-developed condition, this excess runoff volume must be discharged at a rate at which insignificant effective channel work is done.

The Bed Sediment Load moves through transmission of shear stress from the flow of water on the channel bed. An increase in the hydraulic radius (measure of channel flow efficiency through a ratio of the channel's cross sectional area of the flow to its wetted perimeter) corresponds to an increase in shear stress. In order to initiate movement of Bed Sediment Load, however, a shear stress threshold must be exceeded. This is commonly referred to as Critical Shear Stress, and is dependent on sediment and channel characteristics. For a given point on a channel where the bed composition and cross-section is known, the Critical Shear Stress can be related to a flow. The flow that corresponds to the Critical Shear Stress is known as the critical flow, or Qc. For a given cross-section, flows that are below the value for Qc do not initiate Bed Sediment Load movement, while flows above this value do initiate Bed Sediment Load movement.

C.2.2. Geomorphically-Significant Flows in Existing HMPs

SCVURPPP expressed Qc as a percentage of the two-year flow in order to develop a common metric across watersheds of different size, and allow for easy application of HMP performance standards. For the two watersheds studied in detail in the SCVURPPP study, a similar relationship was found where Qc corresponded to 10% of the two-year flow. Several methodologies were used to determine both the two-year flows and the ten-year flows across the evaluated watersheds. The two-year flow was computed based on either the rational method, as described in the Santa Clara Valley Hydrology Procedures, or the Cunnane ranking schema applied to "all event frequency" curves. The ten-year flow was computed based on the Log Pearson type III distribution applied to annual flow frequency curves. This became the basis for

the lower range of geomorphically significant flows under the SCVURPPP HMP and is referred to as Qcp to indicate that it is a percentage of flow. That program also adopted the 10-year flow as the upper end of the range of flows to control with the justification that increases in channel work above the 10-year flow were small for urbanized areas.

A similar study was conducted for the Fairfield-Suisun Urban Runoff Management Program (FSURMP) on two watersheds in Fairfield, California following a geomorphic assessment. That study found Qcp to be 20%t of the pre-development two-year flow. The differences in the two values may be attributable to differences in watershed characteristics in Santa Clara County and Fairfield, the number of channels studied, the methodology used to compute the two-year flow, and the precision of the modeling tools. Channels in Fairfield were found to have a more densely vegetated riparian corridor and may have a higher resistance to increases in shear stresses (FSURMP). Values for Qcp appear to be similar among neighboring watersheds, but there appears to be a range of appropriate Qcp values. The characteristics of individual biomes (climatically and geographically defined areas of ecologically similar climatic conditions, such as communities of plants, animals, and soil organisms, often referred to as ecosystems) should be taken into account when developing a Qcp. For example, Western Washington State, which has more densely vegetated riparian zones than either Fairfield or Santa Clara County, has adopted a Qcp of 50% of the 2-year flow.

The Santa Clara HMP focused on using detention basins for Hydromodification management and emphasized the lower flow control limit for site runoff. Extended detention Hydrologic Control BMP basins can be constructed with multi-stage outlets to manage both the duration and magnitude of flows within a prescribed range. To avoid the erosive effects of extended low flows, the maximum rate (depth) at which runoff is discharged is set below the erosive threshold. Per the Santa Clara HMP, the lower flow control limit was defined as the flow rate that generates critical shear stress on the channel bed and banks. Both Santa Clara and Alameda Counties correlated the lower flow control limit to a value equal to 10% of the 2-year runoff event.

The Contra Costa HMP emphasized the importance of using LID methods to meet Hydromodification Performance Standards. LID approaches to Hydrologic Performance Standards rely on site design and distributed LID BMPs to control the frequency and duration of flows, and to manage hydrograph modification impacts. By minimizing directly connected impervious areas and promoting infiltration, LID approaches mimic natural hydrologic conditions to counteract the hydrologic impacts of development. LID systems are sized to achieve flow control for the range of storms required (from 10% of the 2-year storm up to the 10-year storm).

The San Diego County HMP defined an adaptive lower flow threshold based on the channel susceptibility rating (high, medium, or low). Receiving channels in San Diego County were individually classified by their susceptibility to channel erosion impacts using a critical flow calculator and a channel screening tool developed by SCCWRP. This classification produced three lower flow thresholds which are 0.1Q2, 0.3Q2, and 0.5Q2. The upper range of the management flow was considered the pre-project 10-year storm event.

To date, seven approved HMPs have been published. These include HMPs for SCVURPPP (2005), the CCCWP (2005), the FSURMP (2005), the Alameda Countywide Clean Water Program

(ACCCMP 2005), the San Mateo Countywide Stormwater Pollution Prevention Program (SMCWPPP [formerly STOPPP] 2005), the San Diego County HMP (2009), and the South Orange County HMP (2012). In addition, a number of HMPs were implemented while agencies developed their final plans. Interim HMPs are not detailed in this report because these plans have adopted findings from the above listed HMPs. A summary of flow control standards adopted in each of the approved HMPs in California and western Washington is given in **Table 7**.

Table 7 - Summary of Flow Control Standards – Approved HMPs

Permitting Agency	Q_{cp}	Largest Managed Flow
Alameda County	10% of the 2-year flow (0.1Q2)	10-year flow (Q10)
Contra Costa County	10% of the 2-year flow (0.1Q2)	10-year flow (Q10)
Fairfield-Suisun Urban Runoff Management Program	20% of the 2-year flow (0.2Q2)	10-year flow (Q10)
San Diego County	10, 30, or 50 % of the 2-year flow (0.1Q2, 0.3Q2, or 0.5Q2)	10-year flow (Q10)
San Mateo County	10% of the 2-year flow (0.1Q2)	10-year flow (Q10)
Santa Clara County	10% of the 2-year flow (0.1Q2)	10-year flow (Q10)
South Orange County	10% of the 2-year flow (0.1Q2)	10-year flow (Q10)
Western Washington State	50% of the 2-year flow (0.5Q2)	50-year flow (Q50)

C.2.3. Applicable Flow Thresholds for the SMR

HMPs that have been developed in the San Francisco Bay Area, Northern California (Contra Costa, Santa Clara, and Alameda Counties and the Sacramento area), in Southern California (San Diego, South Orange Counties) vary with regard to the emphasis placed on lower flow control thresholds as compared to other approaches, such as distributed LID methods. The SMR HMP was developed using the lower flow control threshold approach. There is consensus in that both the frequency and duration of flows must be controlled using continuous simulation hydrologic modeling (rather than the standard design storm approach used for flood control design) to manage for potential development impacts. At this point, it is generally accepted that events more frequent than the 10-year flow are the most critical for Hydromodification management, since flows within this range of return period (up to the 10-year event) have been documented to perform the most work on the channel bed and banks. However, the range of analysis could potentially change in the future if new studies provide sufficient evidence warranting a modification.

Rates of sediment production from Southern California rivers depend upon bedrock geology, rates of tectonic uplift, land use, and precipitation (Warrick et al., 2003). The California Geological Survey agency identifies 13 unique geomorphic zones based on geology, faults, topographic relief, and climate (California Department of Conservation, 2002). The SMR is located within the Peninsular Ranges geomorphic zone, whose geology is characterized by the granitic rocks intruding the older metamorphic rocks. South Orange County and San Diego County are also located within the same geomorphic zone, thus exhibits similar macro-scale geomorphic trends to those in the SMR.

The approaches developed for the San Diego County HMP and the South Orange County HMP were approved by the SDRWQCB and selected as the base approach for the SMR HMP. However, the South Orange County program elected not to perform the extensive susceptibility mapping required to correlate channel reaches with variable low flow discharge thresholds. The implementation of HMPs in Northern California, and in San Diego County has shown that numerically larger low flow thresholds generally have very limited applicability in practice. Accordingly, a base low flow threshold (0.1Q2) was selected for this HMP. The selection of the low flow threshold (0.1Q2) was based on other approved HMPs in California with similar hydrologic and geologic conditions. The low flow threshold (0.1Q2) is the most conservative of the potential range identified in the San Diego HMP. Nonetheless, the User may compute a site-specific low flow threshold at their option, following a methodology developed by the User. An example of such a procedure is described in the San Diego County HMP.

If the User opts for developing a site-specific criterion, the selected lower flow threshold should correspond to the critical channel flow that produces the critical shear stress that initiates channel Bed Sediment movement or that erodes the toe of channel banks. For a channel segment that is lined but not exempt by this HMP, the low flow threshold must be computed assuming the lining has been removed.

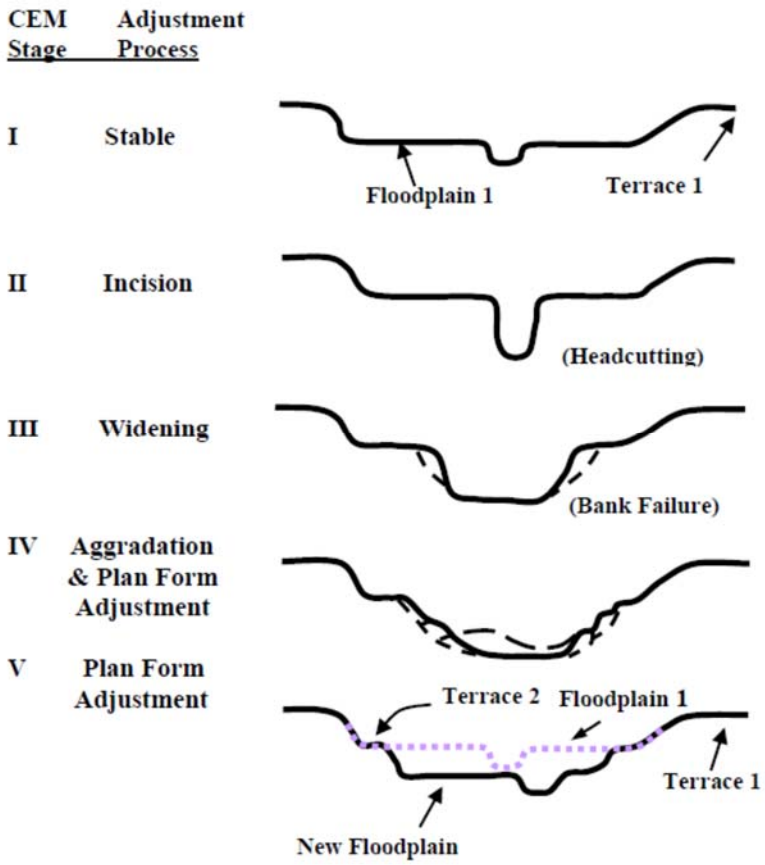
C.3. Classification and Geomorphic Stability of Channels

Numerous channel stability assessment methods have been proposed to help distinguish which channels are most at risk from hydrograph modification impacts and/or define where HMP Performance Standards should apply. Assessment strategies range from purely empirical approaches to channel evolution models to energy-based models (see Simon et al., 2007 for a critical evaluation). Channel stability assessment methods are useful in assessing the impact of urban development or control programs over time. Their value lies in showing trends as changes in a watershed occur, rather than classifying the reach of a discrete channel section at a given point in time.

C.3.1. Empirical approaches and Models

A recent study by Bledsoe et al. (2008) for SCCWRP describes nine types of classification and mapping systems with an emphasis on assessing channel susceptibility in Southern California. The summary below is taken from that study. Bledsoe also provides a summary of the implications of these classification and mapping systems to the development of Hydromodification tools for Southern California. The article provides a detailed breakdown of guidelines for developing Hydromodification tools given the advantages and disadvantages of each system previously assessed.

General Stability Assessment Procedures



By assessing an array of qualitative and quantitative parameters of channels and floodplains, several investigators have developed qualitative assessment systems for channel and river networks. These assessment methods have been incorporated into models used to analyze

channel evolution and stability. Many parameters used to establish methodologies such as the Rosgen approach are extendable to a qualitative assessment of channel response in Californian river networks. Field investigations in Southern California have shown that grade control can be the most important factor in assessing the severity of channel response to Hydromodification. Qualitative methodologies have proven extendable to many regions, and they use many parameters that may provide valuable information for similar assessments in California.

Channel Evolution Models of Incising Channels

The Channel Evolution Model (CEM) developed by Schumm et al. (1984) posits five stages of incised channel instability organized by increasing degrees of instability severity, followed by a final stage of quasi-equilibrium. Work has been done to quantify channel parameters, such as sediment load and specific stream power, through each phase of the CEM. A dimensionless stability diagram was developed by Watson et al. (2002) to represent thresholds in hydraulic and bank stability. This conceptual diagram can be useful for engineering planning and design purposes in channel restoration projects requiring an understanding of the potential for shifts in bank stability.

Figure 15 - Five Stages of the Channel Evolution Model (CEM)

Channel Evolution models Combining Vertical and Lateral Adjustment Trajectories (Schumm et al. 1984)

Originally, CEMs focused primarily on incised channels with geotechnically, rather than fluvially, driven bank failure. Several CEMs have been proposed that incorporate channel responses to erosion and sediment transport into the original framework for channel instability. In these new systems, an emphasis is placed on geomorphic adjustments and stability phases that consider both fluvial and geomorphic factors. The state of Vermont has developed a system of stability classification that suggests channel susceptibility is primarily a function of the existing Rosgen channel type and the current channel condition referenced to a range of variability. This system places more weight on entrenchment (vertical erosion of a channel that occurs faster than the channel can widen, resulting in a more confined channel) and slope than differentiation between bed types.

Equilibrium Models of Supply vs. Transport-capacity / Qualitative Response

The qualitative response model builds on an understanding of the dynamic relationship between the erosive forces of flow and slope relative to the resistive forces of grain size and sediment supply to describe channel responses to adjustments in these parameters. In this system, qualitative schematics provide predictions for channel response to positive or negative fluctuations in physical channel characteristics and Bed Sediment. Refinements to such frameworks have been made to account for channel susceptibility relative to existing capacity and riparian vegetation among other influential characteristics.

Hierarchical Approaches to Mapping Using Aerial Photographs / GIS

It has become an increasingly common practice to characterize channel networks as hierarchical systems. This practice has presented the value in collecting channel and floodplain attributes on a regional scale. Multiple studies have exploited geographical information systems (GIS) to assess hydrogeomorphic behavior at a basin scale. Important valley scale indices such as valley slope, confinement, entrenchment, riparian vegetation influences, and overbank deposits can provide information for river networks in California. Many agencies are developing protocols for geomorphic assessment using GIS and other database associated mapping methodologies. These tools may be useful as they are further developed in a monitoring program, but are not viable at a scale useful for reach-by-reach channel analysis.

The approach taken by this HMP to monitor its effectiveness is embedded in a derivative of the channel classification approach defined by Rosgen (1996). The author distinguishes three different levels of channel classification including: 1) Level I that generally describes channel relief, landform, and valley morphology; 2) Level II that describes the morphology of a channel and associates the later to a channel type based on channel form and Bed Sediment composition. Field measurements of entrenchment, width-to-depth ratio, sinuosity, slope, and representative sampling of channel material may be suitable; and 3) Level III that assesses channel condition and departure. A channel that is geomorphically stable per Rosgen's definition is characterized by two elements: 1) Dimension, pattern, and profile of a channel are maintained over time; and 2) the transport capacity of a watershed's flows and detritus is maintained. As such, physical and biological functions of a geomorphologically stable channel remain at an optimum.

C.3.2. Channel Classification System

Planform Classifications and Predictors

Alluvial channels form a continuum of channel types whose lateral variability is primarily governed by three factors: flow magnitude, bank erodibility, and relative sediment supply. Though many natural channels conform to a gradual continuum between straight and intermediate, meandering, and braided patterns, abrupt transitions in lateral variability imply the existence of geomorphic thresholds where sudden change can occur. The conceptual framework for geomorphic thresholds has proven integral to the study of the effects of disturbance on river and channel patterns. Many empirical and theoretical thresholds have been proposed relating channel power, sediment supply and channel gradient to the transition between braiding and meandering channels. Accounting for the effects of Bed Sediment particle size has been shown to provide a vital modification to the traditional approach of defining a discharge slope combination as the threshold between meandering and braided channel patterns. The many braided planforms in Southern California indicate the need to refine and calibrate established thresholds to river networks of interest. However, at this time there is not a well-accepted model to predict how Hydromodification affects channel planform.

Energy-Based Classifications

The link between channel degradation and urbanization has been studied; however, impervious area is not the solitary factor influencing channel response. Studies have shown that the ratio between specific channel power and median Bed Sediment size D50b, where b is approximately 0.4 to 0.5 for both sand-and gravel-bed channels, can be used as a valuable predictor of channel form. Stream power, which is linearly related to the total discharge, is the most comprehensive descriptor of hydraulic conditions and sedimentation processes in channels. Several studies have been performed relating channel stability to a combination of parameters such as discharge, median Bed Sediment size, and bed slope, as an analog for stream power.

A recent study by Bledsoe et al. (2008) for SCCWRP describes nine types of classification and mapping systems with an emphasis on assessing channel susceptibility in Southern California. The summary below is taken from that study. Bledsoe also provides a summary of the implications of these classification and mapping systems to the development of Hydromodification tools for Southern California. The article provides a detailed breakdown of guidelines for developing Hydromodification tools given the advantages and disadvantages of each system previously assessed.

Sand vs. Gravel Behavior / Threshold vs. Live-Bed Contrasts

It is well recognized that the fluvial-geomorphic behavior varies greatly between sand and gravel/cobble systems. Live bed channels (of which sand channels are good examples) are systems where sediment moves at low flows, and where sediment is frequently in motion. Threshold channels, such as gravel channels, by contrast, require considerable flow to initiate Bed Sediment Load movement. Live bed channels are more sensitive to increases in flow and decreases in sediment supply than threshold channels. Scientific consensus shows that sand bed

channels lacking vertical control show greater sensitivity to changes in flow and sediment transport regimes than do their gravel/cobble counterparts. Factors such as slope, and sedimentation regimes are known to have greater impact on sand bed channels. This can be an important issue for stormwater systems receiving runoff from watersheds composed primarily of channels with sandy substrate. The transition between sand and gravel bed behavior can be rapid, enabling the use of geographic mapping methods to prioritize channel segments according to their susceptibility to the effects of Hydromodification.

Bank Instability Classifications

Early investigations provided the groundwork for bank instability classifications by analyzing shear, beam, and tensile failure mechanisms. The dimensionless stability approach developed by Watson characterized bank stability as a function of hydraulic and geotechnical stability. Rosgen (1996) proposed the widely applied Bank Erosion Hazard Index (BEHI) as a qualitative approach based on the general stability assessment procedures outlined above. Other classification systems, like the CEM, determine bank instability according to channel characteristics that control hydrogeomorphic behavior.

As required per 2010 SMR MS4 Permit Provision F.1.h(1)(a), a Hydromodification Susceptibility Study has been performed as part of this HMP effort to identify and map channel segments that may be vulnerable to Hydromodification and cause a Hydrologic Condition of Concern (HCOC). The study located in APPENDIX D helps Users determine whether or not a project will drain to a potentially susceptible channel segment.

APPENDIX D - Hydromodification Susceptibility Documentation Report and Mapping: Santa Margarita Region

Restoration and Rehabilitation Opportunities in the Santa Margarita Region (refer to Appendix D)

APPENDIX E - HSPF Pervious Land Parameters for SMRHM

Pervious Land Hydrology (PWATER) Parameters

The HSPF hydrology parameters of PWATER are divided into four sections, titled PARM1-4. PARM1 is a series of checks to outline any monthly variability versus constant parameter values within the simulated algorithm; whereas, PARM2 and 3 are a series of climate, geology, topography, and vegetation parameters that require numerical values to be input.

PARM2 involves the basic geometry of the overland flow, the impact of groundwater recession, potential snow impact due to forest cover and the expected infiltration and soil moisture storage. The main parameters of groundwater recession are KVARY and AGWRC. The infiltration and soil moisture storage parameters are INFILT and LZSN.

PARM3 involves the impact of climate temperature during active snow conditions, a wide range of evaporation parameters due to the variability of the onsite soil and existing vegetation and subsurface losses due to groundwater recharge or the existing geology. The main evaporation parameters are INFEXP, INFILD, BASETP, and AGWETP. The parameter for subsurface loss is DEEPFR, which accounts for one of only three major losses from the PWATER water balance (i.e., in addition to evaporation, and lateral and channel outflows).

PARM4 involves the flow and hydrograph characteristics, the expectation of rain interception due to the inherent moisture storage capacity from existing vegetation, land use and/or near surface soil conditions and evaporation due to the root zone of the soil profile. The main interception parameters are CEPSC and UZSN. The parameter for evaporation as a primary function of vegetation is LZETP.

PARM2

KVARY – A groundwater recession flow parameter used to describe non-linear groundwater recession rate (per inches) (initialize with reported values, then calibrate as needed). KVARY is usually one of the last PWATER parameters to be adjusted; it is used when the observed groundwater recession demonstrates a seasonal variability with a faster recession (i.e., higher slope and lower AGWRC values) during wet periods, and the opposite during dry periods. Value ranges are shown in Table A-4. Values that are representative of the conditions in South Orange County have been selected for the SOCHM. Plotting daily flows with a logarithmic scale helps to elucidate the slope of the flow recession.

AGWRC – A groundwater recession rate, or ratio of current groundwater discharge to that from 24 hours earlier (when KVARY is zero) (per day) (estimate, then calibrate).

The overall watershed recession rate is a complex function of watershed conditions, including climate, topography, soils, and land use. Hydrograph separation techniques can be used to estimate the recession rate from observed daily flow data (such as plotting on a logarithmic scale).

INFILT – Index to mean soil infiltration rate (in/hr); (estimate, then calibrate). In HSPF, INFILT is the parameter that effectively controls the overall division of the available moisture from precipitation (after interception) into surface runoff. Since INFILT is not a maximum rate nor an infiltration capacity term, its values are normally much less than published infiltration rates, percolation rates (from soil percolation tests), or permeability rates from the literature. INFILT is primarily a function of soil characteristics, and value ranges have been related to the Soil Conservation Source (SCS) hydrologic soil groups (Donigian and Davis, 1978, p.61, variable INFIL) as follows (**Table 8**):

Table 8 - SCS Hydrologic Soil Group Characteristics

SCS Hydrologic Soil Group	INFILT Estimate		Runoff Potential
	(in/hr)	(mm/hr)	
A	0.4 – 1.0	10.0 – 25.0	Low
B	0.1 – 0.4	2.5 – 10.0	Moderate
C	0.05 – 0.1	1.25 – 2.5	Moderate to High
D	0.01 – 0.05	0.25 – 1.25	High

An alternate estimation method that has not been validated is derived from the premise that the combination of infiltration and interflow in HSPF represents the infiltration commonly modeled in the literature (e.g., Viessman et al., 1989, Chapter 4). With this assumption, the value of 2.0*INFILT*INTFW should approximate the average measured soil infiltration rate at saturation, or mean permeability.

LZSN – Lower zone nominal soil moisture storage (inches). LZSN is related to both precipitation patterns and soil characteristics in the region. Viessman, et al, 1989, provide initial estimates for LZSN in the Stanford Watershed Model (SWM-IV, predecessor model to HSPF) as one-quarter of the mean annual rainfall plus four inches for arid and semiarid regions, or one-eighth annual mean rainfall plus four inches for coastal, humid, or subhumid climates.

PARM3

INFEXP – Exponent that determines how much a deviation from nominal lower zone storage affects the infiltration rate (HSPF Manual, p. 60).

Variations of the Stanford approach have used a POWER variable for this parameter; various values of POWER are included in Donigian and Davis (1978, p. 58). However, the vast majority of HSPF applications have used the default value of 2.0 for this exponent.

INFILD – Ratio of maximum and mean soil infiltration capacities. In the Stanford approach, this parameter has always been set to 2.0, so that the maximum infiltration rate is twice the mean (i.e., input) value; when HSPF was developed, the INFILD parameter was included to allow investigation of this assumption. However, there has been very little research to support using a value other than 2.0.

DEEPFR - The fraction of infiltrating water which is lost to deep aquifers (i.e., inactive groundwater), with the remaining fraction (i.e., 1-DEEPFR) assigned to active groundwater storage that contributes baseflow to the channel.

It is also used to represent any other losses that may not be measured at the flow gauge used for calibration, such as flow around or under the gauge site. Watershed areas at high elevations, or in the upland portion of the watershed, are likely to lose more water to deep groundwater (i.e., groundwater that does not discharge within the area of the watershed), than areas at lower elevations or closer to the gauge.

BASETP – ET by riparian vegetation as active groundwater enters the channel bed; specified as a fraction of potential ET, which is fulfilled only as outflow exists.

If significant riparian vegetation is present in the watershed then non-zero values of BASETP are typically applied. If riparian vegetation is significant, a generic BASETP value of 0.2 is typically representative of the evapotranspiration conditions in the San Juan Hydrologic Unit. This value was established in conjunction with a satisfactory annual water balance.

AGWETP – Fraction of model segment (i.e., pervious land segment) that is subject to direct evaporation from groundwater storage, e.g., wetlands or marsh areas, where the groundwater surface is at or near the land surface, or in areas with phreatophytic vegetation drawing directly from groundwater. This is represented in the model as the fraction of remaining potential ET (i.e., after base ET, interception ET, and upper zone ET are satisfied), that can be met from active groundwater storage.

A value of 0.05 has been selected for inclusion into the SOCHM. This value was adjusted and calibrated in the Aliso Creek watershed HSPF model (Orange County) based on adjustment of the low flow simulation, and ultimately the annual water balance.

PARM4

CEPSC – Amount of rainfall, in inches, which is retained by vegetation, that never reaches the land surface, and is eventually evaporated (estimate, then calibrate). Typical guidance for CEPSC for selected land surfaces is provided in Donigian and Davis (1978, p. 54, variable EPXM) (**Table 9**).

Table 9 - CEPSC for Selected Land Surfaces

Land Cover	Maximum Interception (in)
Grassland	0.10
Cropland	0.10 – 0.25
Forest Cover, light	0.15
Forest Cover, heavy	0.20

LZETP – Index to lower zone evapotranspiration (unitless). LZETP is a coefficient to define the ET opportunity; it affects evapotranspiration from the lower zone, which represents the primary soil moisture storage and root zone of the soil profile. LZETP behaves much like a "crop coefficient" with values mostly in the range of 0.2 to 0.7; as such, it is primarily a function of vegetation. Typical and possible value ranges are shown in **Table 11**, and the following ranges for different vegetation are expected for the "maximum" value during the year (**Table 10**):

Table 10 - LZETP Value Ranges

Land Cover Type	Input Coefficient
Forest	0.6 – 0.8
Grassland 0.4	0.4 - 0.6
Row Crops 0.5	0.5 – 0.7
Barren 0.1	0.1 – 0.4
Wetlands 0.6	0.6 – 0.9

Table 11 - Typical permanent channel cross-section with benchmark locations and points of measurement – Rosgen (1996)

HSPF HYDROLOGY PARAMETERS AND VALUE RANGES

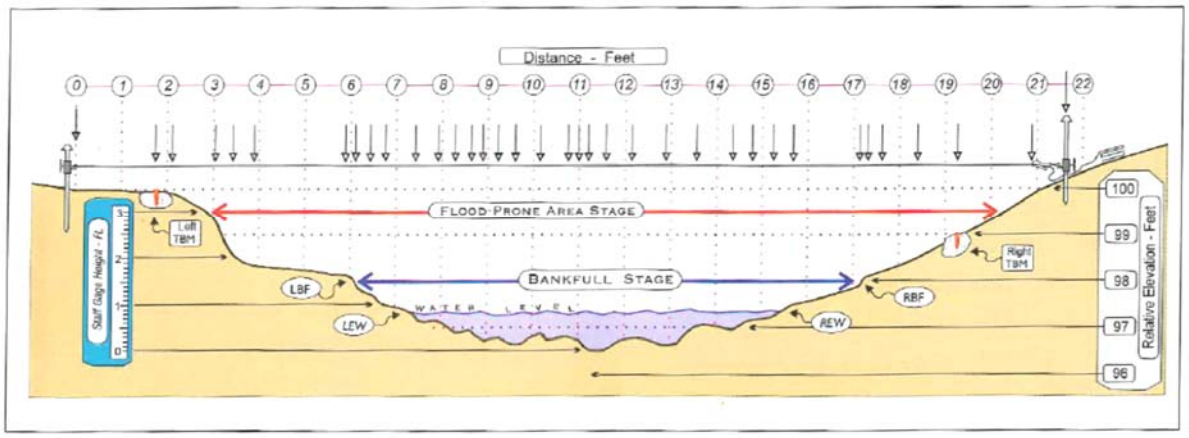
			RANGE OF VALUES					
NAME	DEFINITION	UNITS	TYPICAL		POSSIBLE		FUNCTION OF ...	COMMENT
			MIN	MAX	MIN	MAX		
PWAT - PARM2								
FOREST	Fraction forest cover	none	0.0	0.50	0.0	0.95	Forest cover	Only impact when SNOW is active
LZSN	Lower Zone Nominal Soil Moisture Storage	inches	3.0	8.0	2.0	15.0	Soils, climate	**Calibration**
INFILT	Index to Infiltration Capacity	in/hr	0.01	0.25	0.001	0.50	Soils, land use	**Calibration**, divides surface and subsurface flow
LSUR	Length of overland flow	feet	200	500	100	700	Topography	Estimate from high resolution topo maps or GIS
SLSUR	Slope of overland flow plane	ft/ft	0.01	0.15	0.001	0.30	Topography	Estimate from high resolution topo maps or GIS
KVARY	Variable groundwater recession	1/inches	0.0	3.0	0.0	5.0	Baseflow recession variation	Used when recession rate varies with GW levels
AGWRC	Base groundwater recession	none	0.92	0.99	0.85	0.999	Baseflow recession	**Calibration**
PWAT - PARM3								
PETMAX	Temp below which ET is reduced	deg. F	35.0	45.0	32.0	48.0	Climate, vegetation	Reduces ET near freezing, when SNOW is active
PETMIN	Temp below which ET is set to zero	deg. F	30.0	35.0	30.0	40.0	Climate, vegetation	Reduces ET near freezing, when SNOW is active
INFEXP	Exponent in infiltration equation	none	2.0	2.0	1.0	3.0	Soils variability	Usually default to 2.0
INFILD	Ratio of max/mean infiltration capacities	none	2.0	2.0	1.0	3.0	Soils variability	Usually default to 2.0
DEEPFR	Fraction of GW inflow to deep recharge	none	0.0	0.20	0.0	0.50	Geology, GW recharge	Accounts for subsurface losses
BASETP	Fraction of remaining ET from baseflow	none	0.0	0.05	0.0	0.20	Riparian vegetation	Direct ET from riparian vegetation
AGWETP	Fraction of remaining ET from active GW	none	0.0	0.05	0.0	0.20	Marsh/wetlands extent	Direct ET from shallow GW
PWAT - PARM4								
CEPSC	Interception storage capacity	inches	0.03	0.20	0.01	0.40	Vegetation type/density, land use	Monthly values usually used
UZSN	Upper zone nominal soil moisture storage	inches	0.10	1.0	0.05	2.0	Surface soil conditions, land use	Accounts for near surface retention
NSUR	Manning's n (roughness) for overland flow	none	0.15	0.35	0.05	0.50	Surface conditions, residue, etc.	Monthly values often used for croplands
INTFW	Interflow inflow parameter	none	1.0	3.0	1.0	10.0	Soils, topography, land use	**Calibration**, based on hydrograph separation
IRC	Interflow recession parameter	none	0.5	0.7	0.3	0.85	Soils, topography, land use	Often start with a value of 0.7, and then adjust
LZETP	Lower zone ET parameter	none	0.2	0.7	0.1	0.9	Vegetation type/density, root depth	**Calibration**

Source: USEPA BASINS Technical Note 6

Model assumptions for channel reach infiltration rates were derived through calibration based on data collected within the reaches of Aliso Creek (11 stations) and Rose Creek (6 stations). In the model, infiltration rates vary by soil type. Channel infiltration was calibrated by adjusting a single infiltration value, which was varied for each soil type by factors established from literature ranges (USEPA 2000) of infiltration rates specific to each soil type. The final resulting infiltration rates were 1.368 in/hr (Soil Group A), 0.698 in/hr (Soil Group B), 0.209 in/hr (Soil Group C) and 0.084 in/hr (Soil Group D). The infiltration rates for Soil Groups B, C, and D are within the infiltration range given in literature (Wanielisata et al. 1997). The result for Soil Group A is below the range given in Wanielisata et al. (1997).

APPENDIX F - Channel Classification Procedure

Channel stability over time may be assessed by monitoring the channel for five factors: 1) aggradation; 2) degradation; 3) shifting of particle sizes of channel bed sediment; 4) changing the rate of lateral extension through accelerated bank erosion; and 5) morphological changes following the Channel Evolution Model (Simon et al., 1992). It is recommended that annual assessments of channel stability at cross sections at each monitoring site be carried out at the same time of the year, at the end of the spring season, thus maximizing the chances to monitor similar weather patterns.



Evaluation of vertical or bed stability will serve as the reference method to understand geomorphological changes of a channel over time. Vertical or bed stability will be evaluated at each of the identified cross sections; this field method will identify a potential aggradation or degradation, if any, of the channel. Rate, magnitude, and direction of vertical change, if any, will be quantified.

Vertical or bed stability

Rosgen (1996) has documented a couple of methods for assessing aggradation or degradation over time, including one, known as the "Monumented Cross-sections Method", a derivative of which is utilized by this HMP Monitoring Program. This method requires installation of a permanent monument consisting of a 10-inch stove bolt set up in a pad of concrete to record coordinates and reference elevations to establish site cross sections. However, in order to avoid permanent impacts to private property, modern surveying techniques, including GPS devices, are also available to record cross section locations, and a permanent monument may not be necessary. Field measurements and bank angles may also be used to establish cross sections.

During each cross section survey, a leveled tape line or alternative measuring technique may be used. Figure 16 depicts the intercept of the rod with the leveled tape line.

Figure 16 - Typical permanent channel cross section with benchmark locations and points of measurement – Rosgen (1996)

The following guidance is provided where a level tape is used:

- Locate the permanent benchmark, if applicable, on both sides of the channel (or, if on one side, a bearing for the transect is needed)
- Stretch the tape very tight with spring clamp and tape level
- Locate tape at same elevation as reference bolt on benchmark
- Read distance and elevation reading of rod intercept with tape
- Measure major features, such as:
    - Left benchmark (LBM)
    - Left terrace/floodplain (LT, LFP)
    - Left bankfull (LBF)
    - Left bank (LB)
    - Left edge of water (LEW)
    - Various bed features, bars, etc.
    - Thalweg (TW)
    - Inner berm features (IB)
    - Right edge of water (REW)
    - Right bank (RB)
    - Right bankfull (RBF)
    - Right terrace/floodplain (RT, RFP)
    - Right benchmark (RBM)

Measurements will include the floodplain, terraces, and channel adjacent slopes. Other surveying procedures such as auto or laser levels and total station surveys may be adapted from the described "measuring tape and elevation rod" method. If technically feasible, any exceptional event associated with a level higher than the bankfull level will to be marked and indicated on the cross section. The cross section will be plotted for each measurement and compared to previous cross sections to evaluate bed stability. Finally, the longitudinal slope will be assessed based on measurements taken at two consecutive cross sections.

Each channel segment being surveyed will initially be classified per the simplified Rosgen system of channel classification (Rosgen, 1996). Classification will be possible upon identification of the following parameters: flood-prone width, bankfull width, bankfull depth, and longitudinal slope. **Figure 17** shows the different types of channels per Rosgen channel classification (Rosgen, 1996). During each subsequent year, surveyed channel segments will be compared to the six-stage Channel Evolution Model defined by Simon, as well as the previous year's cross section data, to correlate any potential impacts of urbanization to a change of channel geomorphology (Simon et al., 1992). A channel segment will be considered stable over time if features of the channel segment (such as dimension, pattern, and profile) are maintained, and the channel system neither aggrades nor degrades.

Figure 17 - Simplified Rosgen Channel Classification (Rosgen, 1996)

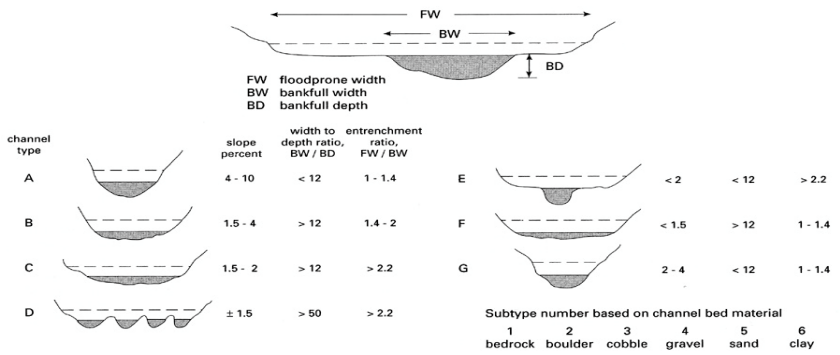


Figure 1.12 The Rosgen system of channel classification.

APPENDIX G - Santa Margarita Region Hydrology Model Guidance Manual

APPENDIX H - Conducting a Site-Specific Hydromodification Analysis

A User may choose to develop a site-specific Hydromodification susceptibility analysis in lieu of using the continuous simulation tool provided by the SMR HMP. The site-specific analysis must be developed to demonstrate that the project will not adversely impact the receiving channel through either changes in the receiving channel hydrograph, or changes in Bed Sediment Load supply to the channel.

The following items are not intended to be an approach to complete the analysis, rather, they are provided for information as suggestions for the engineering analysis. Each project will have unique conditions and will require a customized approach for analysis. A site-specific analysis may or may not be ultimately approved by the Copermittee with jurisdiction over the project site. It is the responsibility of the User to assess the potential for an analysis to successfully demonstrate that the project is consistent with the guidelines of this HMP.

1. It is recommended that the User develop a study approach and outline, and review it with the Copermittee with jurisdiction over the project site prior to beginning the full study.
2. The study must demonstrate that the project is consistent with the requirements of the 2010 SMR MS4 Permit and this HMP.
3. Site-specific information to characterize Bed Sediment gradation, flow and rainfall data, and watershed hydrologic parameters will be required. Continuous simulation is required.
4. An objective of the study may be to determine if the loss of Bed Sediment Load from the project-site to the receiving channel can be partially or fully managed by additional management of the runoff discharge from the project-site.
5. Sediment transport modeling has inherent uncertainty. The Copermittee with jurisdiction over the project site may not approve a site-specific analysis if it is apparent that the change in conditions that will be modeled are about the same magnitude as the model uncertainty.

The selected lower flow threshold should correspond to the critical channel flow that produces the Critical Shear Stress that initiates channel Bed Sediment Load movement or that erodes the toe of channel banks of a comparable soft-bottom channel.

The method of analysis, including the specific modeling program, the sediment transport function, the reach of the receiving water to be modeled, the method of determining Bed Sediment discharge in the receiving channel, the method of determining Bed Sediment discharge from the project-site, the period of record for continuous simulation and other parameters are left to the discretion of the User. The study report should document and justify the approach, selected models and methods, data requirements, analysis method and results for review.

APPENDIX I - Identification of a Site-Specific Low Flow Threshold

If allowed by the Copermittee with jurisdiction over the project site, Users have the option to use a site-specific low flow threshold for individual projects instead of 10% of the 2-year peak flow specified in the HMP.

A User may assess the viability of pursuing a site-specific low flow threshold based on the results of a planning-level analysis that is presented in this Appendix. The planning-level analysis consists of a critical flow sensitivity assessment, which provides the User with a general indication that a site-specific low flow threshold may be appropriate, but is not sufficient to quantify the threshold. The stepwise approach is consistent with that developed for the San Diego County HMP (2011).

The demonstration of an applicable low flow threshold must be performed based on field geomorphic evaluation, non-uniform hydraulic modeling, and sediment continuity modeling. This Appendix provides general concepts on these topics. A person knowledgeable in sediment processes should be consulted if the User desires to take the next step and establish a site-specific low flow threshold.

A. For Planning Purposes Only: Simplified Stepwise Approach

For initial planning purposes, the User may run the desktop-level analysis using the proposed empirical equations and assess the viability of pursuing a site-specific low flow threshold. To establish viability of a site-specific threshold, the User may perform and document the findings of each of the following six steps.

The simplified stepwise approach is only provided as an attempt to assist the User with a simplified method. The uncertainty associated with each of the variables of the simplified approach can potentially falsely influence the results. It is the User's responsibility to analyze the results and the geomorphic environment of the downstream channel before attempting to pursue a site-specific low flow threshold.

Step A-1: Identify the Typical Range of Rainfall Conditions for the HMP Area

The purpose of Step 1 is to identify the mean annual precipitation at the project site based on existing records from a nearby precipitation station. The mean annual precipitation serves as an input to characterize the dominant discharge for the receiving channel. Based on 70+ years of District SMR rainfall records, the mean annual precipitation ranges from 11.6 to 20.6 inches in the SMR. The User should identify on **Figure 3** of the main document, the meteorological zone where the project site is located, and subsequently refer to **Table 12** to select the associated mean annual precipitation.

Table 12 - SMR Mean Annual Precipitation per Meteorological Zone

Meteorological Zone	Mean Annual Precipitation (in inches)
Eastern Slopes	14.7
Temecula Valley	15.8
Western Plateau	20.6
Wildomar / North Murrieta	11.6

Step A-2: Identify a Range of Typical Receiving Channel Dimensions for Each Watershed Area

Empirical relationships have been developed to express channel dimensions (width, depth, and to a lesser extent, gradient) as a function of the dominant discharge. For undeveloped channels in semi-arid parts of the U.S. such as in the SMR, dominant discharge can be approximated by the 5-year discharge flow.

Step A-2.a – The dominant discharge, Qbf, assumed to be approximately equivalent to the 5-year peak discharge (Q5), may be estimated using the USGS regional regression for undeveloped watersheds in the South Coast Region (Waananen and Crippen, 1977). This equation calculates Q5 (cfs) as a function of watershed area (sq. mi.) as determined in Step 2, and mean annual precipitation (MAP, in/yr) as determined in Step 1. The relationship is:

$$Q_5(cfs) = 0.4 \cdot [Watershed\ Area\ (sq.mi)]^{0.77} \cdot [Mean\ Annual\ Precipitation\ (inches)]^{1.69}$$

Step A-2.b –Identification of the width and the depth of each channel reach: The User may iteratively identify the type of channel as defined in **Table 13** that most corresponds to each individual channel reach that is selected within the domain of analysis (defined in APPENDIX C). In addition to the channel type, **Table 13** identifies the source and the empirical channel geometry relationships. Empirical relationships were developed based on channel geometry and hydrology in Southern California.

Table 13 - Empirical relationships for Channel Dimensions

Channel Type	Source	Empirical Channel Geometry Relationships
Undeveloped channels in Southern California – narrow, deep, and steep dimensions	Coleman et al., 2005	$Width(ft) = 0.6012 \cdot Q_{bf}^{0.6875}$ $Depth(ft) = 0.3854 \cdot Q_{bf}^{0.3652}$ Q_{bf} in cfs
Gravel channels – wide, shallow, flat braided dimensions	Parker et al., 2007	$Width(m) = 4.63 \cdot \frac{Q_{bf}^{2/5}}{9.81^{1/5}} \cdot \left[\frac{Q_{bf} \cdot d_{50}^2}{\sqrt{9.81 \cdot d_{50}}}\right]^{0.0667}$ $Depth(m) = 0.382 \cdot \frac{Q_{bf}^{2/5}}{9.81^{1/5}}$ Q_{bf} in the bankfull discharge in m^3/s d_{50} is the diameter of median channel material in m
Medium width, depth, and gradient channels	Hey and Thorne, 1986	$Width(m) = 2.73 \cdot Q_{bf}^{0.5}$ $Depth(m) = 0.22 \cdot Width^{0.37} \cdot d_{50}^{-0.11}$ Q_{bf} in the bankfull discharge in m^3/s d_{50} is the diameter of median channel material in m

Step A-3.c – Compute a channel slope using Manning's equation such that the wetted cross-sectional area at bankfull depth conveys the dominant discharge. Manning's equation is expressed as:

$$Q = 1.486 \cdot \frac{A \cdot R^{0.67} \cdot \sqrt{s}}{n}$$

Where:

- Q = Flowrate (cfs)
- A = Cross-Section Flow Area (ft2)
- R = Hydraulic Radius (ft) = A / P
- P = Wetted Perimeter (ft)
- s = Energy Gradient Assumed Equal to Longitudinal Slope (ft/ft)
- n = Manning Roughness (unitless)

For planning purposes, the User can assume a Manning Roughness value of 0.025, corresponding to a non-vegetated, straight channel of small slope, after aging whose Bed Sediment is composed

of colloidal alluvial silt (ASCE No.77, 1992). However, it is suggested that the User determine the retardance coefficient from
Table 14. This reflects the small, ephemeral receiving channels which are prevalent in Southern California. A different Manning Roughness value may be used only if it has been previously approved by the Copermittee with jurisdiction over the project site. A sensitivity analysis performed in the San Diego HMP found that the retardance coefficient had little effect on the estimated critical shear flow rate.

Table 14 - Critical Shear Stress per Sediment Type (Source: ASCE No.77, 1992)

Material	n	Clear Water		Water Transporting Colloidal Silts	
		V (fps)	τ (lb/ft2)	V (fps)	τ (lb/ft2)
Fine sand, colloidal	0.020	1.50	0.027	2.50	0.075
Sand loam, noncolloidal	0.020	1.75	0.037	2.50	0.075
Silt loam, noncolloidal	0.020	2.00	0.048	3.00	0.11
Alluvial silts, noncolloidal	0.020	2.00	0.048	3.50	0.15
Ordinary firm loam	0.020	2.50	0.075	3.50	0.15
Volcanic ash	0.020	2.50	0.075	3.50	0.15
Stiff clay, very colloidal	0.025	3.75	0.26	5.00	0.46
Alluvial silts, colloidal	0.025	3.75	0.26	5.00	0.46
Shales and hardpans	0.025	6.00	0.67	6.00	0.67
Fine gravel	0.020	2.50	0.075	5.00	0.32
Graded loam to cobbles when noncolloidal	0.030	3.75	0.38	5.00	0.66
Graded silts to cobbles when colloidal	0.030	4.00	0.43	5.50	0.80
Coarse gravel, noncolloidal	0.025	4.00	0.30	6.00	0.67
Cobbles and shingles	0.035	5.00	0.91	5.50	1.10

Step A-3: Identify a Range of Typical Channel Material for Receiving Channels

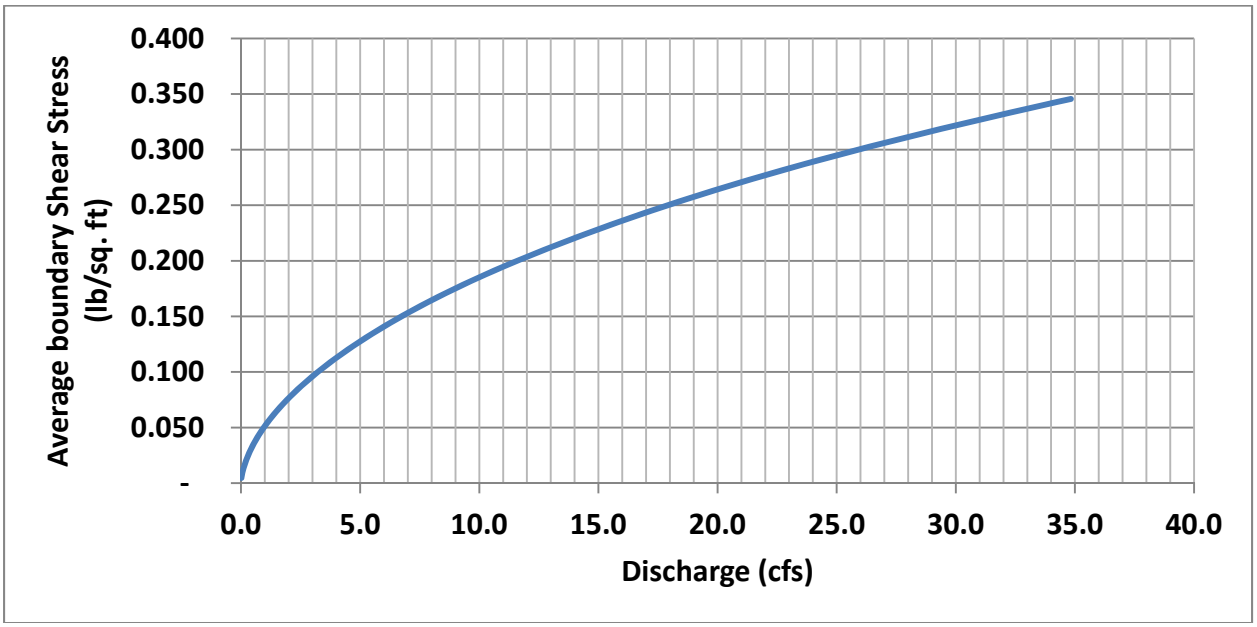
The User should identify the weakest predominant type of Bed Sediment in each section of the receiving channel within the domain of analysis. A simple identification from aerial imagery, available photography, or existing technical documentation is deemed sufficient for planning purposes, or a field review or a geotechnical investigation can be used. The User should

subsequently identify the critical shear stress associated with each type of predominant Bed Sediment using Error! Reference source not found.
Table 14 presents a nonexhaustive list of critical shear stresses for typical channel materials and covers the range of Critical Shear Stresses to be encountered in the SMR.
Table 14 may be used for planning purposes only.

Appropriate references for Critical Shear Stress values are provided in ASCE No.77 (1992) and Fischenich (2001). To account for the effects of vegetation density and channel irregularities, the applied shear stress can be partitioned into form and bed/bank roughness components, and the lowest value of d50 be used for calculations. Other references include the procedure for application of allowable velocity to determine the Critical Shear Stress or equivalent allowable velocity associated with a specific type of Bed Sediment. Design of Open Channels, TR-25 (USDA, 1977) will guide the User through the allowable velocity approach, which relates allowable velocity to sediment concentration, grain diameter of the non-cohesive boundary material, and plasticity index and soil characteristics for cohesive boundary material. Another effective reference is the National Engineering Handbook Part 654, Chapter 8, which contains the Shields diagram and describes the allowable shear stress approach (NEH, 2007).

Step A-4: Identify the Flow Rate at Which Boundary Shear Stress Exceeds Critical Shear Stress for the Channel and Material

The tractive force theory was initially described in Shield's diagram (1936) and further translated into an equation by the Bureau of Reclamation (1987). The tractive force theory establishes that Bed Sediment Load is being displaced when the shear stress applied on the boundary of a particle of Bed Sediment exceeds the critical shear stress associated with that particle. The average boundary shear stress on a particle of Bed Sediment may be expressed as:



$$\tau = \gamma \cdot R \cdot s$$

Where:

- τ = Effective Shear Stress of d_{50} from sieve analysis (lb/ft2)
- γ = Unit Weight of Water (62.4 lb/ft3)
- R= Hydraulic Radius (ft) as determined in Step 2
- s = Longitudinal slope (ft/ft) as determined in Step 2.c

Using Manning's equation for the established channel cross-section, roughness, and gradient, the flow depth is iterated to produce a shear stress rating curve for each of the channel section selected within the domain of analysis. A shear stress rating curve correlates the average boundary shear stress to a discharge, which can be as high as the dominant discharge in this exercise. For the purpose of the exercise, an example shear stress rating curve is shown in **Figure 8**. The example shear stress rating curve was developed with the following parameters: s= 0.005 ft/ft; n= 0.035; side slope = 1H: 1W; bankfull depth = 1.51 feet; bankfull width = 7.91 feet.

Figure 18 - Example Shear Stress Rating Curve

Based on the Critical Shear Stress identified in Step 4, the User should identify on each shear stress rating curve, Qcrit, or the flow rate at which boundary shear stress equals critical shear stress.

Step A-5: Express Critical Flow As A Function of Q2

The User may use the USGS regional regression of the 2-year peak discharge for the South Coast Region (Waananen and Crippen, 1977) to determine the 2-year peak discharge in each channel reach selected within the domain of analysis. The regression equation is expressed, as follows:

$$Q_2(\text{cfs}) = 0.14 \cdot [\text{Watershed Area (sq. mi)}]^{0.72} \cdot [\text{Mean Annual Precipitation (inches)}]^{1.62}$$

The critical flow (Qcrit) is expressed as a function of Q2 to remain consistent with the standardized relationship stated in existing HMPs throughout California.

Step A-6: Identify the Most Conservative Low Flow Threshold

In a final step, the User should summarize in a tabular format the findings of the stepwise approach applied to each section of channel. An example of such tabular representation is showcased in **Table 15**, in which critical flow rates are grouped by type of channel material.

Table 15 - Summary Table of Critical Flow Rates per Section of Channel

Drainage Management Area	Trib Area	Mean Annual Precip	5-year Flowrate	2-year Flowrate	Critical Flowrate	Low Flow Threshold	Bankfull Width	Bankfull Depth
	A	MAP	Q5	Q2	Qcrit	Qcrit/Q2	W	D
	sq mi	in/yr	cfs	cfs	cfs	% of Q2	ft	ft
τ_{crit} = 0.025 lb/ft2, sand bed (low end)								
Section A1	1	15.8	42.5	12.2	0.296	**2.4%**	7.91	1.51
τ_{crit} = 0.05 lb/ft2, sand bed (high end)								
Section A2	1	15.8	42.5	12.2	0.947	**7.7%**	7.91	1.51
τ_{crit} = 0.12 lb/ft2, gravel								
Section A3	1	15.8	42.5	12.2	4.452	**36.4%**	7.91	1.51

In the above example, for Section A1, the ratio between the critical flow and the 2-year peak flow is computed as: (0.296 cfs) / (12.2 cfs) = 0.024 = 2.4%.

From the summary table, the User should identify the most conservative low flow threshold among all downstream sections. For instance, in the presented example, the User should select 2.4% Q2 as the site-specific low flow threshold. In this instance, a site-specific low flow threshold would not be advantageous for the project.

B. For Consideration and Approval by the Copermittee with jurisdiction over the project site: Full-Scale Geomorphic Assessment

For consideration and approval of a site-specific low flow threshold by the Copermittee with jurisdiction over the project site, demonstration must be established based on field geomorphic evaluation, nonuniform hydraulic modeling, and sediment continuity modeling. A person familiar with sediment transport should be consulted if the User was to establish a site-specific low flow threshold.

The field geomorphic assessment, to be performed within the domain of analysis, should identify the geometry of each selected cross-section and characterize the associated Bed Sediment Load. The geomorphic evaluation requires surveying the cross-section and longitudinal profile geometry of the active channel, estimating the hydraulic roughness of the channel, and evaluating the critical shear stress (pounds per square foot) of the most sensitive bed and bank material. For non-cohesive material, a Wolman pebble count or sieve analysis is used to obtain a grain size distribution, which can be converted to Critical Shear Stress using an empirical relationship or reference tables in the literature. For cohesive material, an in-situ jet test or reference tables are used. For banks reinforced with vegetation, reference tables are generally used.

The site-specific hydrologic and hydraulic evaluation should determine the 2-year peak discharge Q2 based on a flow gage record in the receiving channel or a continuous hydrologic model, if available. In computing Q2, the original condition of the watershed tributary to the channel, before development, should be considered. This provides a means of apportioning the critical flow in a channel to individual projects (on a pro-rata area basis) that discharge to that channel,

such that cumulative discharges do not exceed the critical flow (Qcrit) in the channel of concern. This flow apportionment must be provided as a part of the analysis by the User.

The User must demonstrate through a channel stability impact assessment that the changes to both the amount of Bed Sediment transported and the amount of Bed Sediment supplied to the channel, will maintain the general trends of aggradation and degradation in the impacted channel reaches, which are representative of the dynamic equilibrium of a channel.

I. Introduction

This Santa Margarita Region (SMR) Hydromodification Management Plan (HMP) has been established to manage increases in runoff discharge rates and durations from applicable Priority Development Projects (PDPs); the overall goal of the SMR HMP is to ensure that geomorphic stability within SMR channels will not be compromised as a result of receiving runoff discharges from PDPs. The level of understanding of the variables influencing the geomorphologic changes in channels receiving urban runoff may be deduced through monitoring. As such, this SMR HMP Monitoring Program defines a Hydromodification monitoring approach, as required by Provision F.1.h.(1)(m) of San Diego Regional Board Water Quality Control Board (SDRWQCB) Order No. R9-2010-0016 (2010 Permit); Provision F.1.h.(1)(m) requires that the SMR HMP:

> Include a description of monitoring and other program evaluations to be conducted to assess the effectiveness of implementation of the HMP. Monitoring and other program evaluations must include an evaluation of changes to physical (e.g., cross section, slope, discharge rate, vegetation, pervious/impervious area) and biological (e.g., habitat quality, benthic flora and fauna, IBI scores) conditions of receiving water channels as areas with Priority Development Projects are constructed (i.e. pre- and post-project), as appropriate.

The goals of the SMR HMP Monitoring Program are to:

- Gather data which can assist in assessing susceptibility and characterizing the physical conditions of surface waters to Hydromodification in the upper SMR Watershed Management Area (WMA);
- Gather data which may be used in future monitoring and development of the SMR WMA Water Quality Improvement Plan (WQIP), required under SDRWQCB Order No. R9-2013-0001, as amended by R9-2015-001 and R9-2015-0100 (Regional Permit);
- Assess whether monitored surface waters are impacted by Hydromodification; where impacts may be identified, those surface waters will be considered during assessment of priority water quality conditions in the SMR WMA WQIP; and
- Provide gathered information to existing stream rehabilitation efforts in the upper SMR.

The SMR HMP Monitoring Program proposes to achieve these goals by conducting monitoring at two sites within the SMR WMA, through Fiscal Year 2018-2019; additional sites throughout the SMR WMA will also be monitored through a collaborative effort with the Southern California Monitoring Coalition (SMC) to account for both temporal and spatial variability. The gathered data will also be used to supplement an ongoing effort spearheaded by the Meadowview Community Association and the U.S. Fish and Wildlife Service (USFWS) to rehabilitate a reach of Meadowview Stream, which is located in the northern portion of the city of Temecula.

This HMP Monitoring Program also includes a mechanism for assessing and addressing cumulative Hydromodification impacts from development projects within the SMR, as required by 2010 Permit Provision F.1.h(1)(n). After assessment and survey data is gathered from each site, it will be utilized to track site geomorphic evolution, and assess what type of impacts may have occurred; if necessary, those impacts can then be addressed within the context of the SMR WMA's identified highest priority water quality conditions.

II. Background

In accordance with 2010 Permit Provision F.1.h(5)(a), the SMR Co-Permittees submitted a public-reviewed draft SMR HMP, with SMR HMP Monitoring Program Plan, to the SDRWQCB on June 30, 2013; comments were received from the SDRWQCB, and a revised draft SMR HMP was re-submitted in March 2014, pursuant to 2010 Permit Provision F.1.h(5)(b). The SDRWQCB found the revised draft SMR HMP to be conditionally adequate, and prescribed an effective date for the final SMR HMP: July 11, 2014. This effective date provided a unique situation for the SMR HMP Monitoring Program in the following ways:

- The effective date of the SMR HMP was less than one and a half years before the expiration date of the 2010 Permit. Provision F.1.h(1)(m) of the 2010 Permit prescribes that the SMR HMP Monitoring Program must, "assess the effectiveness of implementation of the HMP". Similarly, Provision F.1.h(1)(l) requires development of a protocol to evaluate potential impacts which may be observed from Priority Development Projects (PDPs) which have implemented the hydrologic performance standard of the SMR HMP. However, by the end of Fiscal Year 2014-2015, there were no PDPs conditioned to implement the hydrologic andor sediment supply standards of the SMR HMP which had been constructed in the SMR WMA, and it was anticipated that more time may pass before a significant number of hydrologic and sediment control BMPs could be constructed and assessed within the SMR for monitoring purposes.
- By May 8, 2013, the SDRWQCB had developed and adopted the Regional Permit, and had notified the SMR Co-Permittees that upon expiration of their 2010 Permit, they would be enrolled into the Regional Permit. The Regional Permit allows the SMR Co-Permittees to focus their efforts on identified highest water quality priorities in the SMR WMA, and to develop management measures, goals and schedules in the SMR WQIP to address those priorities. The Regional Permit also requires that Co-Permittees monitor for Hydromodification and other impacts, with the purpose of assessing the effectiveness of measures implemented in key watershed areas to address the WMAs identified highest priority water quality conditions. This is in contrast to the 2010 Permit, which requires Hydromodification monitoring at selected individual sites located downstream from PDPs, to assess whether the science behind the hydrologic and sediment performance standards is operating as intended. Monitoring driven by management actions at particular locations (i.e., a local scale) will always benefit from information gathered from one or more regional-scale reference sites that can characterize natural or background variability (SCCWRP, 2012). Therefore, the effectiveness of future measures implemented under the SMR WQIP can only be properly assessed if background conditions regarding Hydromodification of SMR WMA streams are monitored and assessed prior to implementation of those measures.
- In December 2014, representatives from the Meadowview Community Association (Association) contacted the Riverside County Flood Control and Water Conservation District regarding a reach of the Meadowview stream which is located on Association property within the city of Temecula, and displays substantial mass wasting of the stream banks. Observed impacts include damage to infrastructure (an adjacent road partially collapsed during a recent storm event), and possible threats to public safety (eroding stream banks appear to be encroaching upon open trails used by pedestrians, cyclists and equestrians). The Association and the USFWS are currently working on a plan to

implement environmentally sustainable solutions to restore and stabilize the stream's banks. The Co-Permittees wish to support the proposed project by contributing data, reports and any other helpful information gathered under this SMR HMP Monitoring Program to project stakeholders. Beginning July 2015, coordination with the Association, project stakeholders and applicable federal agencies was underway, and a license agreement to gain access to the site for monitoring was executed in November 2015.

Given this unique situation of the Co-Permittees' need to revise the 2014 SMR HMP Evaluation Program and the need to obtain data to assist with the requirements of the Regional Permit, the Co-Permittees saw an opportunity to modify the Hydromodification Monitoring Program to accomplish both efforts, and meet the monitoring program goals noted above. The program concept was presented to SDRWQCB staff, and preliminarily agreed upon on July 15, 2015.

III. Monitoring Measures

Monitoring measures aim at identifying potential susceptibility of monitored stream reaches to Hydromodification and then tracking their geomorphology over time. The Co-Permittees will collect the following Hydromodification monitoring observations and measurements at the two monitoring locations described in Section IV.D., below:

1) Channel conditions, including:
   a) Channel dimensions
   b) Hydrologic and geomorphic conditions
   c) Presence and condition of vegetation and habitat
2) Location of discharge points
3) Photo documentation of existing erosion, with location (i.e., latitude and longitude coordinates) where photos were taken
4) Measurement or estimate of dimensions of any existing channel bed or bank eroded areas, including length, width, and depth of any incisions
5) Known or suspected cause(s) of existing downstream erosion impact, including flow, soil, slope, and vegetation conditions, as well as upstream land uses and contributing new and existing development

A. Field Methods

Stream Susceptibility

The "Hydromodification Screening Tools: Field Manual for Assessing Channel Susceptibility" developed by SCCWRP (Technical Report 606, 2010) will be utilized as appropriate to make the observations and measurements described above. In support of the Hydromodification monitoring observations and measurements noted above, two data types will be calculated through GIS analysis and collected during field efforts:

1) Landscape GIS Metrics
   a) Contributing drainage area above the point of interest
   b) Mean annual area-weighted precipitation
   c) Geomorphic confinement: valley bottom width at site
   d) Valley slope at site
   e) Upstream land use coverage

2) Site-Specific Field Metrics
   a) Bank angle
   b) Bank height
   c) Stream gradient
   d) Substrate particle size (if necessary)
   e) Vertical susceptibility
   f) Lateral susceptibility

A stream reach at each location will be delineated. Once the stream reach to be assessed has been determined, the risk potential for mass wasting (erosion) will be measured. At representative transects, the left and right bank angles and bank heights will be measured using a stadia rod and

gravity-driven protractor. If necessary, the stream substrate particle size (pebble count) will be measured and a median particle size will be determined. Vertical and lateral susceptibility to bank wasting will then be assessed. Vertical susceptibility will first be assessed by recording the status of three streambed parameters: composition of the stream substrate, armoring potential (i.e., bed consolidation), and grade control presence and effectiveness. Lateral susceptibility will then be assessed through a decision tree using a combination of vertical susceptibility rating, bank stability threshold, and valley width index to determine the lateral susceptibility.

Stream Geomorphology

In addition to assessing susceptibility, geomorphology of each monitored site will be tracked over time; a channel survey at each sites' selected cross sectional transects will be conducted annually. The channel survey will consist of collecting topographic and bathymetric measurements along each cross section to characterize morphology and longitudinal slope of the channel segment. Four parameters will be surveyed: 1) the floodprone width; 2) the bankfull width; 3) the bankfull depth; and 4) the longitudinal slope. Initially, each surveyed channel segment will be classified per the simplified Rosgen system of channel classification (Rosgen, 1996), as detailed in Figure 1. During each subsequent year, surveyed channel segments will be compared to the six-stage Channel Evolution Model defined by Simon, as well as the previous year's cross section data, to correlate any potential impacts of urbanization to a change of channel geomorphology (Simon et al., 1992). The six-stage Channel Evolution Model and steps for assessing geomorphology of each monitored site are described in more detail in Section IV.A. below.

Figure 1: Simplified Rosgen Channel Classification

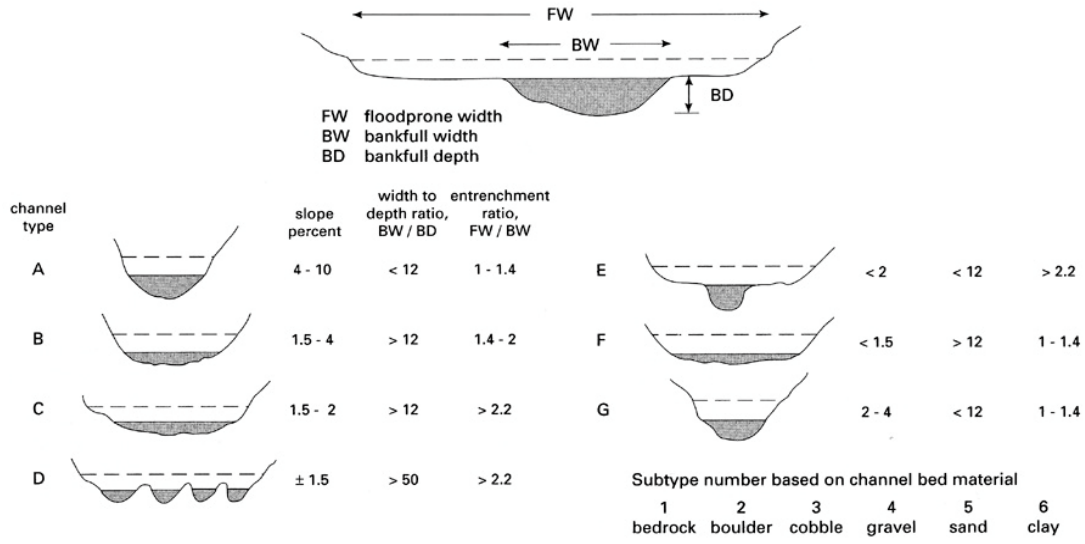

Figure 1.12 The Rosgen system of channel classification.

(Rosgen, 1996)

Stream Bioassessment

Biological communities can provide a direct representation of the health of flowing channel segments; however, the SMR is a predominantly non-perennial region, where flows in the vast majority of streams are characterized as 'episodic'. Conversely, 2010 Permit Provision F.1.h(1)(m) requires that the SMR HMP Monitoring Program "include an evaluation of changes to…..biological (e.g., habitat quality benthic flora and fauna, IBI scores) conditions of receiving water channels as areas with Priority Development Projects are constructed, as appropriate."

As part of the State of California's Surface Water Ambient Monitoring Program (SWAMP) Bioassessment program, the Southern California Index of Biotic Integrity (SoCal IBI) and the California Stream Condition Index (CSCI) scoring systems, amongst a handful of other SWAMP Standard Operating Procedures, have been evaluated for their applicability in perennial and non-perennial streams. Current research suggests that these tools provide a good indication of the benthic macroinvertebrate (BMI) health in perennial streams and for a sub-set of non-perennial streams. Non-perennial streams exhibit a wide spectrum of hydrologic conditions from flowing the majority of the year, to flowing for only a short duration after storm events. Current research by SCCWRP and the SDRWQCB is investigating the extent of applicability of the scoring tools in non-perennial stream systems. However, currently there is no SWAMP approved scoring method for assessing streams on the ephemeral end of the non-perennial stream spectrum, rather only experimental metrics have been discussed or employed in the past few years by a handful of technical workgroups or interested parties whose goal remains to develop the tools to assess California's ephemeral or 'episodic' streams.

Therefore, while monitoring methods described in this SMR HMP Monitoring Plan can be used in assessing physical habitat characteristics (i.e., substrate composition, canopy cover, flow, channel alteration) because a viable biological assessment procedure does not yet exist for episodic streams, it will not include biological assessments at this time.

B. Spatial and Temporal Variability

The single most important factor affecting the temporal variability inherent to measuring channel aggradation and degradation is variable inter-annual rainfall frequency and intensity. Droughts in California can last years, with little to no rainfall occurring in southern California. During El Niño years, anomalously high storm frequencies and intensities can result in sudden geomorphic changes. Rainfall intensity also varies intra-annually.

Physical habitat metrics and cross sectional transects of a representative set of channel segments is important to capture the range of watershed conditions of the SMR. Other important factors that reflect channel responses to Hydromodification include channel grade, watershed area, and channel sinuosity. In addition to channel and watershed features, location within the watershed is an important consideration.

The two selected monitoring stations (described in Section IV.D. below) are distributed within the SMR WMA to provide for representative geographic variability.

C. Monitoring at Additional Sites

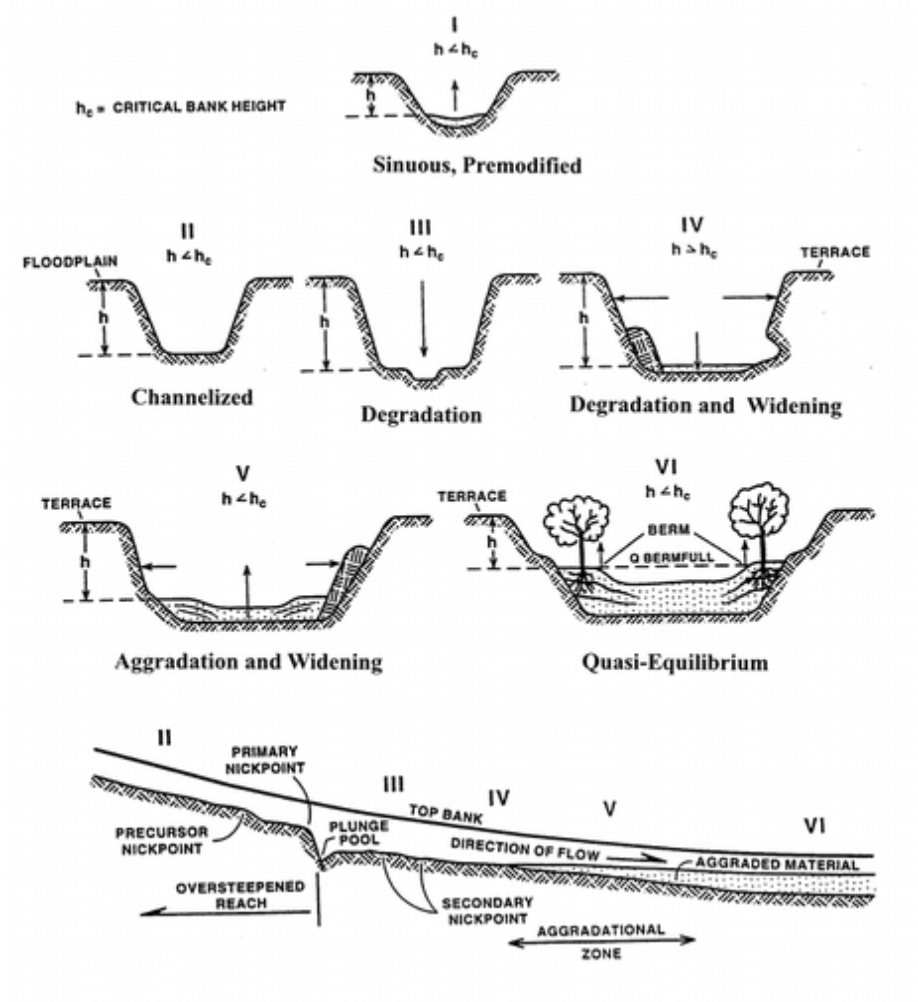
In accordance with Section E.7 of Attachment E of the 2010 Permit, the SMR Co-Permittees partner with other southern California MS4 Co-Permittees in the development and implementation of the southern California regional stream survey, through the SMC. The SMC's current workplan (see: SCCWRP Technical Report 849 - http://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/849_SMCWorkplan2015.pdf) describes the program for the years 2015 through 2019, and includes addition of an enhanced physical habitat assessment with Hydromodification module; this added method to assess susceptibility of southern California streams to Hydromodification is consistent with the methodology being utilized by this SMR HMP Monitoring Program.

Over the five-year term of SMC's survey, both condition sites and trend sites will be monitored annually throughout southern California. Within the SMR, one trend site has been selected which is located on Sandia Canyon Creek, adjacent to De Luz Road in unincorporated Riverside County; this is a site which will initially be assessed for susceptibility to Hydromodification impacts (i.e., physical habitat assessment with Hydromodification module, the same methodology utilized by this SMR HMP Monitoring Program), and will again be monitored each year throughout the five-year period of the SMC study. Additionally, SMC will monitor one condition site each year within the SMR WMA, with site locations being distributed throughout the upper SMR, and varying from year to year.

The SMR Co-Permittees will utilize data gathered during the first three years of the SMC survey to supplement the findings and final report of this SMR HMP Monitoring Program.

IV. Data Analysis and Reporting

The SMR HMP Monitoring Program extends through Fiscal Year 2018-2019; this period of time is necessary to implement monitoring, analyze data from selected sites and the SMC survey, and to account for spatial and temporal variability of the conditions in the SMR. Implementation of the SMR HMP Monitoring Program will be discussed in the Transitional SMR Annual Reports, pursuant to Regional Permit Provision F.3.b(2). Analytical data and a final report will be submitted to the SDRWQCB at the end of the monitoring program period, tentatively in Fall 2019.



A. Data Analysis

Desktop GIS analysis for calculating drainage area, valley width, and valley slope for each site will be performed using the USGS National Elevation Dataset Digital Elevation Models.

The risk of bank failure will be calculated using a combination of bank height and bank angle field measures relative to the probability of mass wasting equation and table published in the Hydromodification Screening Tool document. Lateral and vertical susceptibility will be assessed through pebble counts, field measures, and decision trees available in the screening tool document.

Geomorphology of each site will be tracked by annually surveying each site's selected cross sectional transects. The temporal evolution in geomorphology, if any, of the surveyed channel segment will be compared to the six-stage Channel Evolution Model defined by Simon et al., as well as the previous year's cross section data, to correlate any potential impacts of urbanization to a change of channel geomorphology (Simon et al., 1992). Figure 2 illustrates the six-stage sequence of incised channel evolution (Simon et al., 1992). A channel segment will be considered stable over time if features of the channel segment (such as dimension, pattern, and profile) are maintained, and the channel system neither aggrades nor degrades. General guidance for conducting channel surveys and the classification procedure are described in more detail in Appendix F of the SMR HMP.

Figure 2: Six-Stage Channel Evolution Model

(Simon et al, 1992)

B. Mechanism for Assessing Cumulative Impacts

2010 Permit Provision F.1.h(1)(n) requires that the SMR HMP "include mechanisms for assessing and addressing cumulative impacts of Priority Development Projects within a watershed on channel morphology." The mechanism that will be implemented in upper SMR is described here:

- As described in Section III.A. above, stream susceptibility will be assessed during the first monitoring event at each site;
- Channel geometry surveys will be performed annually, using pertinent surveying techniques, including cross sectional survey, and each channel will be initially classified using the simplified Rosgen system of channel classification;
- Each subsequent year, surveyed cross section data from both monitoring locations will be compared to the previous year's cross section data to determine if significant aggradation or degradation is detected. A significant aggradation or degradation of the channel segment will be deemed by the analyst as a rapid change of the morphology of the channel (cross section) that follows Simon's Channel Evolution Model;

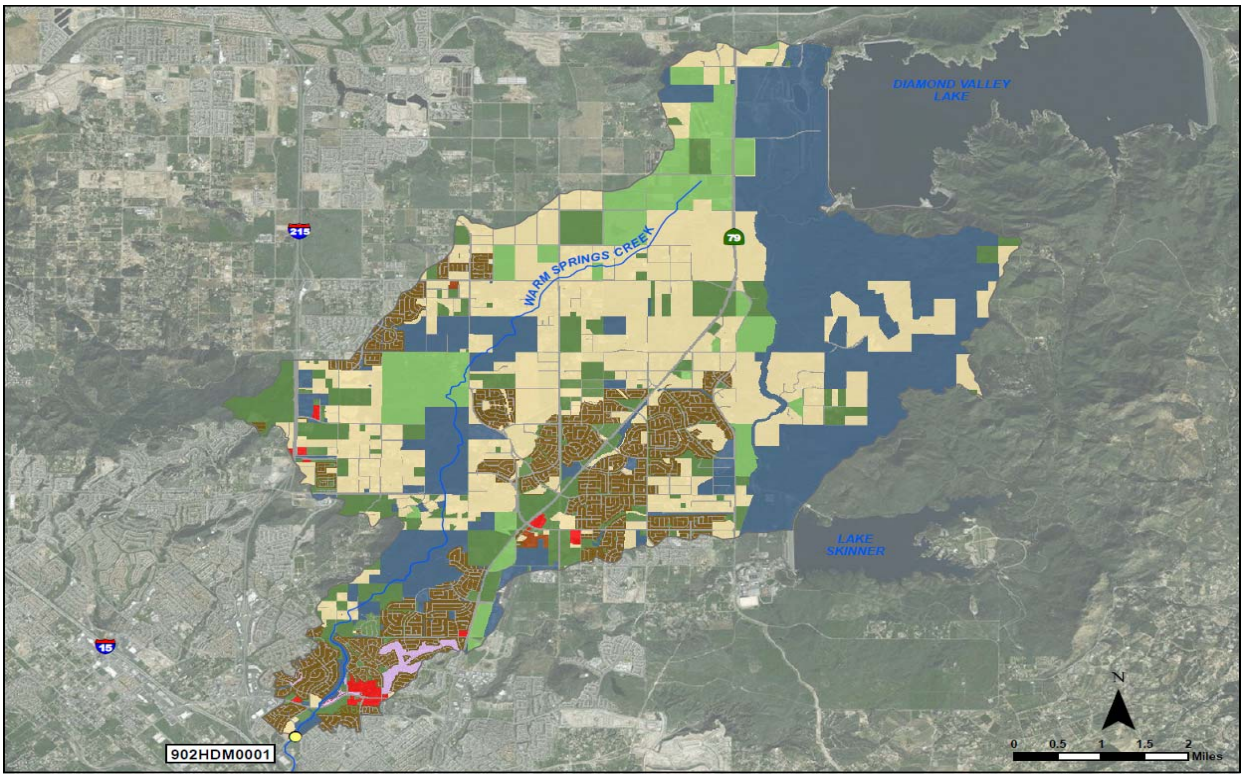
- Where the analyst observes a rapid change of channel morphology, the tributary area of the impacted channel segment may be investigated in an attempt to identify the potential source(s) for the degradation of the morphology of the channel segment; and
- Stream reaches identified as impacted will be considered when the SMR Co-Permittees assess and prioritize SMR WMA water quality conditions to be addressed by the SMR WQIP.

C. Reporting

The term of the SMR HMP Monitoring Program will extend through Fiscal Year 2018-2019. As previously mentioned, implementation of this SMR HMP Monitoring Program will be discussed in the Transitional SMR Annual Reports, pursuant to Regional Permit Provision F.3.b(2). Additionally, after the last monitoring year (projected to be Fiscal Year 2017-2018), data will be gathered from the two monitored sites (described in Section IV.D. below) and from the SMC southern California regional stream survey, to be compiled into a final report, which will be submitted to the SDRWQCB, tentatively in Fall 2019. The final report will contain:

- An explanation of field monitoring and GIS methods utilized;
- A summary of the monitored sites;
- A characterization of the physical conditions of monitored surface waters to Hydromodification;
- An assessment of whether any of the monitored sites exhibited impacts due to Hydromodification, and any sources which may be suspected; and
- A description of how the data gathered under this SMR HMP Monitoring Program will be used in future monitoring and/or implementation efforts.

D. Monitoring Sites



Site Name – Warm Springs Creek (902HDM001)

Location:

Latitude 33°32'54.02" N

Longitude 117°10'14.24" W

Monitoring site 902HDM001 is located in Warm Springs Creek approximately 720 meters downstream of the Murrieta Hot Springs Road crossing. The monitoring reach is approximately 165 meters long with relatively homogenous bank and channel characteristics.

*Drainage area boundary and acreage may be subject to revision as additional data is received.

Site Name – Meadowview Stream at Meadowview Community Association (902HDM002)

Location:

Latitude 33°31'22.66" N

Longitude 117° 7'51.46" W

Monitoring site 902HDM002 is located in Meadowview Stream where it bisects property of the Meadowview Community Association. This reach of the creek is approximately 1000 meters long, between Del Rey Road at the upstream boundary and Via Norte at the downstream boundary. Surface flow is ephemeral in this reach, flowing only during storms and for a short time thereafter.

*Drainage area boundary and acreage may be subject to revision as additional data is received.
